THERE is an airy lightness about the cut-leaved varieties of such trees as the Beech, Alder, Birch, and others, that renders them invaluable aids in producing a pretty effect in ornamental planting, an effect entirely different from that derived from other cut-leaved, or, to speak correctly, pinnate-leaved trees, such as the Ash, Walnut,

A form of the Cut-leaved Beech.

Ailantus and others. I know of few trees more beautiful than a Cut-leaved Beech as you see it in May after its leaves are unfolded of a tender sap-green colour, and if it happily associates with a Copper Beech, glowing at that early date with ruddy foliage, greater beauty is added to it. The Cut-leaved Beeches are simply forms of the common Beech, and differ in no other respect from it except in the cutting of the leaves. The fineness of the cutting of the foliage varies considerably, some forms being much more finely cut than others,

Another form of the Cut-leaved Beech.

and distinct names have been given to the sorts, according to the difference of cutting. There are several names, the commonest being heterophylla, asplenifolia, incisa, filicifolia, laciniata, and comptoniaefolia, but these are mere names for simply the Cut-leaved Beech, and in proof of this I have seen at least three of the so-called forms growing on the same tree. At Shopwyke, near Chichester, I saw last autumn a tree half of whose foliage was of the normal broad-leaved Beech, the rest cut-leaved, and this

did not result from grafting, as the cut-leaved branches were in parts intermixed with the other. Sometimes a whole tree of the cut-leaved form has been known to revert to the common form. The two illustrations herewith given represent two twigs with variously cut leafage. There is a distinct sort called salicifolia, or Willow-leaved Beech, that has the leaves long and narrow like a Willow, and not incised at all; but this is not constant, as the leaves will often appear cut on the same branch. But what concerns us most here is the value of the Cut-leaved Beech for ornamental planting. Like other good things among trees, one can have too many of them about a place. The position for a Cut-leaved Beech to show itself to the best advantage is on the outskirts of a heavy group of broad-leaved trees, such as the outermost point of a bend in the group. You then see the full beauty and gracefulness of the tree, its delicate green and distinct rounded outline. A good spreading Cut-leaved Beech makes a capital shade tree on a lawn, not being so dense as the common Beech. A Cut-leaved Beech does not associate well with the common Beech; they are too much alike, and the difference in foliage is not so apparent as when seen in company with entirely different trees; but, as before remarked, the copper Beech goes admirably with it, and there is a multitude of ways it can be used with telling effect. Little need be said about the culture of the Beech, as everyone who knows anything about trees is aware that Beeches of all sorts grow finest in chalky districts or in deep sandy loams. They do not thrive well on peaty soils; they grow certainly, but are very slow, and never develop characteristic growth. But there is scarcely any kind of soil on which one may not plant Beeches with successful results. Those who are making lists of trees to finish the planting season should bear in mind the Cut-leaved Beech, and they invariably do the copper or purple Beech.

The Myrtle-leaved Portugal Laurel.—The common Portugal Laurel, fine Evergreen as it undoubtedly is, may become very monotonous if planted too plentifully in small places, but its monotony may be relieved if a few of the small Myrtle-leaved variety is associated with it. This variety has a very neat appearance, as it is more compact in growth, has much smaller leaves, but of the same rich shining green. In small gardens where a good winter effect is wanted it would be found useful.

Ilex dipyrrena.—London classed this Holly with the species "that may probably be found half-hardy." But when he wrote this thirty years ago, *I. dipyrrena* was scarcely known in gardens; now it is known to be as hardy as our native Holly, and, moreover, a very handsome Evergreen, different from any variety of *I. Aquifolium*. The leaves are of a very dark, dull green, quite smooth-edged, and show a tendency to droop. It is not without value in ornamental planting where variety of effect is sought. In the best tree nurseries it may be bought, and specimens as much as 15 feet and 20 feet high may be met with. It is somewhat pyramidal and compact in growth, and reminds one of the Japanese Evergreen Oaks, such as *Quercus Euergeri*. This Holly grows wild in Nepal and Chinese Tartary.

The Chequer Berry, called also the Partridge Berry by the Americans and *Gaultheria procumbens* by botanists, is a diminutive little trailing shrub which I should like to meet with more frequently in private gardens, as it is one of the few precious shrubs that one can depend upon for winter effect on a rockery or rootery. It makes a dense creeping carpet of small leathery foliage of a deep green, and during autumn and winter the foliage is studded with bright scarlet berries about the size of Peas. It has a charming effect, especially when growing among old tree roots, where it seems most at home. It blooms in May, but the flowers, being so tiny and white, are not worth taking into account. It likes a

peaty soil and half shady spot. It is a Canadian plant, and also reaches the sunny mountains of Carolina. It grows wild in dry woods, mostly in sandy soils, and is strictly a cold climate or mountain plant. It may be seen at Kew in the rock garden.

LEYCESTERIA FORMOSA.

THIS is one of the many beautiful shrubs introduced to our gardens from the mountainous regions of Northern India. It is without doubt one of the handsomest hardy shrubs we have, possessing a beauty peculiarly its own. It is a medium-sized shrub, growing to a height of 6 feet or more in places most adapted for it. It is of elegant growth, as each long shoot takes a graceful curve. The bark is of a singularly bright green and so are the leaves, and these contrasted with the flowers and berries have a fine effect in autumn. The flowers are white, but the floral leaves or bracts are of a deep vinous purple, and these are really the showiest part of the inflorescence. The berries, too, are very ornamental, being of the same colour as the bracts. For several weeks towards the close of summer and far into autumn the Leycesteria is one of the most attractive of open-air shrubs, and the fact that it grows well in almost any soil adds to its value. It cannot be called a perfectly hardy shrub, because even in the south it is liable to be badly injured during severe winters, but it is rarely killed outright. During the terrible winters of 1880-81 it was killed to the ground in many places, but by May it again threw up vigorous shoots. It is an unsafe shrub for a heavy soil in a low spot, but the finest specimens I have seen were growing on heavy clay in mid-Sussex. These were planted on a high exposed bank by the side of the public road, and were fully 10 feet through and 6 feet high. I conclude, therefore, that the Leycesteria likes a strong soil and a dryish spot. Shade or even partial shade is not essential, though it is a capital shrub for forming an undergrowth under tall trees, provided that the shade is not too dense. It has been advocated even for covert planting, but it has not been used much in that way, probably on account of its not being grown on a large scale for the purpose in nurseries. Some beautiful effects may be obtained by it in pleasure grounds by planting large masses of it, with here and there an outlying isolated specimen cultivated so as to induce luxuriant growth. It is beautiful, too, when a few plants of it are seen rising out of a low undergrowth of such Evergreens as Mahonia, for then its bare winter effect is not so much noticed. There are many ways of planting this shrub with others so as to show off its beauty. In many old-fashioned gardens I have seen luxuriant specimens growing against warm walls, or conservative walls as they used to be commonly called. It has been, no doubt, planted in such places under the impression that it is tender. Other perfectly hardy shrubs used often to be grown on conservative walls, and a beautiful effect they produced. The Leycesteria was introduced about the year 1824, so that it is quite an old garden plant. It grows wild on the highest mountains surrounding the valley of Nepal, at elevations of from 6000 feet to 8000 feet. It grows there in forests of Pine and Oak. W. G.

Californian Wax Myrtle (*Myrica californica*).—In this North American shrub, commonly called the Californian Candleberry Myrtle, we have a most valuable Evergreen for English gardens, a shrub almost unknown beyond the limits of botanical collections, but it is assuredly one that would pay tree nurserymen to grow, propagate, and make it better known, as it is a first-rate Evergreen, hardy beyond a doubt, and grows and thrives in the poorest soils. It is a crooked-growing shrub, but in no sense an untidy-looking bush. It may be best described as being similar to the common Sweet Gale (*M. Gale*) in growth, but far superior to it, because its foliage retains a fresh green appearance throughout the winter, and it always forms a dense thicket of green, old plants being as much as 8 feet high. The leaves are narrow,

about 3 inches long, coarsely toothed, and are disposed in tufts on the branches. Unlike the Sweet Gale, there is no pleasant odour to the leaves when bruised. For dry, sandy mounds there is not a more suitable shrub, as it grows naturally on hill-sides. In the neighbourhood of San Francisco it grows into huge bushes. Another American *Myrica* (*M. cerifera*), is called the Wax Myrtle on account of wax being obtained from the berries. These abound in wax, and when boiled the wax is extracted. In the parts of North America where the shrub grows plentifully in a wild state the wax is used as a substitute for tallow for candles; these give a brilliant light, and while burning give off an agreeable perfume. The Wax Myrtle grows wild over a wide range in America. It is found in Carolina and Virginia, and extends northwards to New England and Pennsylvania. It is a very old shrub in English gardens, having been introduced so long ago as 1699, but even now one only meets with it in very old gardens and botanical collections.

The Butcher's Broom.—Mr. Wilks (p. 154) appears to doubt the hardness of this native shrub, but my impression is that there is not a hardier shrub in gardens than it. The most luxuriant growth I have seen of it is that at the foot of the chalk hills of Surrey, Sussex, and Hampshire, notably about Box Hill, near Dorking, and if I remember rightly it is one of the chief features in the open-air garden at Sir Trevor Lawrence's residence at Burford, which nestles snugly at the base of the hill; at Kew it grows admirably on the light soil, particularly along the bottom of the large mound near the Cumberland Gate entrance. It is doubtful if it would succeed if protected, as Mr. Wilks suggests, in a conservatory or winter garden, for, like other hardy plants under glass, it would soon become a prey to thrips and other pests. The observations of others in different parts of the country would, I am sure, be valuable to many readers. It is important to state the nature of the soil as well as the situation the plant is growing in.—W. G.

Variiegated Wellingtonia.—On the lawn in front of our conservatory there is a strong tree of the golden variegated *Wellingtonia gigantea*. Although it has not reverted to the green form in the slightest degree and grows freely, I have never been much enraptured with it, and at the present time if allowed to do as I liked with it, this winter would be its last. On the whole the variegated or most golden portions are not much damaged by either frosts or winds, but the leader is evidently badly injured, and a *Wellingtonia* without a good centre is far from being ornamental.—W. I. M.

Chimonanthus fragrans and Jasminum nudiflorum.—These useful wall plants have braved the cold of the winter so far well, and have been in flower here for these last five weeks or more. Although the individual flowers of the *Chimonanthus* are not very imposing in the way of colour, they make up for that deficiency by their fragrance. A small handful of flowering sprays of this plant placed in a vase will scent a whole room sweetly for days, while the *Jasmine* can be cut and used effectively amongst other flowers. Our plant of *Chimonanthus*, which is an old one, covers 25 feet of a 12 feet-high east wall. It would extend a good deal further, but that is its allotted space. When done blooming it is pruned hard back to last year's wood; all suckers that come up about the main stem are also cut close in, and the strongest shoots are shortened back about halfway. This is all the treatment it receives, except keeping it fastened to the wall, and when flowering time comes round the shoots are clothed with bloom like the shoots of a well managed Peach tree. The *Jasmine* is treated in the same way, except that it is not cut back in summer. It is allowed to grow freely and to assume its natural drooping habit, and when in flower in winter it has a cheerful appearance. We have it on a west and north-west aspect, and it does well on both.—W. WATSON, *Englehurst, Farley, Hants.*

The Algerian Silver Fir (*Abies baborensis*) is without question one of the handsomest Conifers

yet introduced, as it embodies all the points constituting a first rate ornamental tree. It has very handsome growth, is symmetrical in outline, yet not too stiff; the foliage is a bright cheerful green; it is a rapid grower and is thoroughly hardy, the late spell of cold having had no effect upon it. It is a strong grower, even on the poor soil at Kew, where by its luxuriant growth it may be at once singled out from the rest. Its affinity is with the common Silver Fir (*A. pectinata*), but nobody would mistake the one for the other. We have not seen any specimen in this country bearing cones, but Carrière states that the cones are borne erect, and from 5 inches to 8 inches long. This Fir is a native of Algeria, where it grows on the mountains at an elevation of from 4000 feet to 6000 feet, and, according to Veitch's Manual, is accompanied by the Mount Atlas Cedar (*Cedrus atlantica*). It was introduced to Europe about twenty years ago, M. de Lannoy having brought it into France. It has been till lately known as *A. numidica*, and is still grown under that name in nurseries.—G.

RAINFALL IN 1886.

SUBJOINED is the rainfall of 1886 here (Belvedere House, Mullingar) and at Belvoir Castle, Grantham. Belvoir is 237 feet above sea level, and Belvedere 367 feet. Both are in midland counties.

BELVEDERE, WEST MEATH.

Rain gauge: diameter of funnel, 5 inches; height of top above ground, 1 foot; above sea level, 367 feet.

Month.	Total depth.	Greatest fall in 24 hours.	Date.	Number of days on which '01 or more fell.

W. INGRAM.

The rainfall in Ireland exceeds that at Belvoir by no less than 8.12 inches. There are, however, sixty-three more days on which rain fell, entered at Belvoir, but that is probably owing to the fact that rainfalls only reaching '01 inches are registered there, and that these are probably due to local evaporation. In both places herbaceous plants, Roses, and bulbous plants do well. Evergreens do better at Belvedere, but the

striking difference between the two places is in fruit growing. While at Belvoir all hardy fruits are remarkably successful, at Belvedere even Apples are an uncertain crop. A striking exception is the *Pyrus Maulei*, which has fruited well in the open. It makes a most excellent preserve. It would be very desirable if the success or failure of the same plants in different parts of the United Kingdom could be carefully noted. There is nothing so misleading as a nurseryman's catalogue, and the arbitrary distinction of hardy, tender, and semi-hardy. The presence of limestone in the soil, of moisture in the atmosphere, of prevailing bursts of wind, of elevation, render a plant hardy in one place and tender in another. If a catalogue was properly drawn up, the conditions under which plants grew in their native habitat should be stated, and new introductions should not be supposed to thrive under conditions totally dissimilar to those under which they have been discovered.

BRINSLEY MARLAY.

PROPAGATING.

FERNS—This is the best season for sowing Fern spores, as if done now they pass rapidly through their more critical stages, which are, generally speaking, after they have been sown from one to two months, that is when the surface of the soil becomes thickly covered with their small mossy-like growth, and before any signs of young fronds can be seen. With regard to the composition of the soil on which the spores are to be sown, there are many different opinions, but I prefer a mixture of good yellow loam, peat, and sand, the whole sifted fine before using. Many choose a rough surface on which to sow the spores, and under these conditions they germinate just as well, but when necessary to be pricked off, that operation is rendered far more difficult if they are growing on lumpy soil. Before using, the soil should be thoroughly baked, in order to destroy all signs of life in it, whether animal or vegetable, for if this is not done, very frequently on the soil being placed in a position favourable to the growth of the spores, the whole surface will be overrun with coniferæ. This evil will be greatly lessened if the soil is baked beforehand. Whatever sized pots are used for sowing the spores in, they must be perfectly clean, and filled to within 2 inches of the top with broken crocks, then over these may be placed a thin layer of fibrous peat, and after that the above-mentioned compost. This must be pressed down moderately firm, and when finished should present a perfectly smooth and level surface. After that a good watering, or rather a succession of waterings, sufficient to give the entire contents of the pots a thorough soaking, must be given, and when this is the case all is then ready for the reception of the seed. The fertile fronds required for sowing having been gathered a little time previously, and laid in white paper in a dry place, will discharge their spores, which, owing to the colour of the paper, are very easily seen. All that is then necessary is to sprinkle the fine dust like spores as thinly as possible on the still moistened surface of the soil, to which they will readily adhere. They will then need to be so situated that a uniform state of moisture is maintained, and to ensure this a good plan is to place them in a close propagating case, and, in addition, to lay a pane of glass over each pot. Thus treated, they will need but very little water before germination takes place, but should they become dry, the better way to moisten the soil is to stand the pots in a pan of water sufficiently deep to reach about half-way up each pot. The moisture will, in this case, percolate through the whole of the soil, and thoroughly moisten it, without in the least disturbing the surface. As soon as the young Ferns make their appearance in the shape of a Moss-like carpet of green on the soil, the glass laid on the pots had better be taken off, and at the same time each pot should be examined, and any Moss that may be forming on the surface at once removed, for it is not done directly, the future growth of the Moss and Fern becomes inseparably associated, and in the end

the Moss will choke the remaining vegetation. Even after the glasses are removed from the pots, the young Ferns make more satisfactory progress if kept in the humid atmosphere of a propagating case, but constant supervision will be needed to see that they do not damp off, for should any signs of decay make its appearance a certain amount of air must be given to the case by tilting the lights, and if that does not stop the decay, or the spores become too much crowded, they must be pricked off.

To succeed with this operation, the pots and soil must be prepared as for seed sowing, except that, instead of being pressed down moderately firm, it is left quite soft, though level at the top. Then with a pointed stick take a small cluster of the growing spores and place them in position on the surface of the soil in the newly prepared pot. The soil being so light, a gentle pressure with the forefinger will keep them in position without in the least bruising the growing spores. After a pot is filled with these little tufts, each standing well clear of its neighbour, the whole should receive a good watering through a fine rose, which will settle everything in its place. After this the pots may be returned to the case, when, if the operation has been carefully performed, they will grow away without check.

Some kinds are far more liable than others to damp off during their earlier stages, the Maiden-hairs being, as a rule, among the more vigorous, while *Pteris tremula*, which is such a strong-growing kind when established, is, when first germinating, as subject to decay as any. Many kinds will need pricking off two or three times before fronds are pushed up; indeed, from one good clean pot of young seedlings in its first stage it is often easy to make a dozen pots all full of growing plants. By the time the fronds are seen, the curious Liver-wort-looking prothallus of a Fern will, in some cases at least, spread out to quite a considerable size and produce several young plants around the edge. The spore of a Fern differs widely from the seed of a plant, as this latter contains the future plant in embryo; while in the case of a Fern the spore may be rather regarded as a flower, for the organs of fructification are undeveloped when first sown. Owing to this, the possibility of raising hybrid Ferns has been frequently demonstrated, the mingling of the spores of two distinct species or varieties before sowing having resulted in a very mixed crop, the greater part of which would be simply a reproduction of the two kinds sown, while not unfrequently some individuals, exactly intermediate in character between the two, will make their appearance. This is especially observable in the genus *Adiantum*, for where several kinds are raised in this way, some very curious forms generally result therefrom. The temperature at which Fern spores should be kept when sown will, of course, depend upon the natural requirements of the plant, but, generally speaking, the better plan is to keep them a little warmer than the temperature required for the adult plant.

DIVISION.—This in various ways is also available for the propagation of many Ferns, especially those of a tufted growth, such as several kinds of Maiden-hair, the smaller *Pteris*, and a host of others. Another class amenable to this mode of increase is represented by those kinds with creeping rhizomes, such as *Gleichenias*, *Davallias*, many *Polypodiums*, and others. This latter class, even when the rhizome is above the surface of the soil, frequently produces roots on their own account, so that no further care is necessary than to take them off, and after potting place them under conditions favourable to growth. In the case of those of a tufted character, the usual plan is to shake them out of their pots as carefully as possible, and then divide the plant to the extent required. Any that may be obtained in this way are all the better if kept close for a little time till root action recommences.

This method was at one time much employed for the propagation of the cuneatum section of *Adian-*

tums, but those raised from spores are now generally preferred, especially where needed in the shape of small plants, as they are when young better furnished and of a more pleasing outline than those obtained by division. A great many Ferns, again, are prolific, that is to say, they produce perfect plants on the fronds, and in that case all that is necessary is to bring them in contact with the soil under conditions favourable to growth. This may be effected in two ways, either by bending down the fronds while still on the plant, or cutting them off and pegging them down on pots of soil. In this latter case especially they are better if kept close for a time; indeed, most Ferns make far more rapid progress if nursed during their earlier stages.

One caution to be particularly observed in sowing Fern spores is that, owing to their minute character and lightness, they float readily in the air, so that should several sorts be sown at one time the pots required for any one kind must be isolated, and the actual sowing carried out at some distance from the pots prepared for others, as if this is not carefully followed out a confusing mixture will in most cases be the result, and then the stronger growing kinds are very liable to destroy the weaker ones. Another precaution is to wipe the hands on a towel after each sort is finished and before commencing another. A good illustration of the way in which the spores of Ferns are transported from place to place is to be observed in most structures devoted to their culture, as young plants may be seen springing up in all directions, and often clothing a damp wall or some such spot with quite a mass of greenery. Though many kinds grow thus readily, there are, on the other hand, numbers that require very great care to raise them successfully from spores. T.

ORCHIDS.

W. H. GOWER.

CATTLEYS ALL THE YEAR ROUND.

ORCHID BLOSSOMS, owing to their singularity of form, variety in the way of colour, and often delicate perfume, are always appreciated. They are also remarkably persistent, some kinds retaining their beauty for months together. This to a great extent may be attributed to their not being fertilised by insects, for Orchid flowers, as well as those of other plants, quickly fade when fertilised. Certain genera of Orchids become now and then fashionable. At present *Lady's Slippers* carry the sway. Of these we have nearly two hundred species, varieties, and garden hybrids—an enormous number when one considers that some forty years ago they might have been counted on the fingers. At that time one who could successfully grow air-plants, as they were then called, was deemed a clever plantsman; and we fear the notion that they are difficult to cultivate has not yet been got wholly rid of. Be that as it may, it be may safely asserted that the majority of Orchids are as easily grown as ordinary stove or greenhouse plants. Much depends on the way in which their culture is commenced. Many begin with small imported plants, but these are just the plants on which the most skill and attention require to be bestowed in order to restore them to health and vigour, and years may elapse before they make a good display; therefore beginners should always start with fair-sized specimens of typical forms. Amongst these the selection should be confined to the most showy kinds, as, for instance, to the *Cattleyas*, which are all strikingly beautiful, although their flowers, as a rule, are not so long-lived as those of many of the *Odontoglossums*; nevertheless, they will keep in good condition for three or four weeks; therefore, anyone possessing from twelve to eighteen varieties of *Cattleya* may reasonably hope to have flowers the whole year round.

In January and February *C. Trianae* and *C. Percivaliana* will be in bloom; the flowers of the former measure about 6 inches across, and consist for the most part of some shade of blush or lilac, with a rosy purple lip, stained in the throat with some shade of orange or yellow. In *Percivaliana* the sepals and petals are deep blush, and the lip, which is prettily fringed, is deep magenta-crimson, with a paler margin, the centre being more or less mottled and streaked with velvety crimson and gold. In March *C. amethystoglossa* and *C. Mendeli* come into bloom; the first grows about 3 feet high, and usually produces from six to ten thick fleshy flowers upon a spike, sometimes many more; the sepals and petals are white, suffused with rose, and profusely dotted and spotted with purplish magenta, the lip being rich purple, flushed with magenta. *C. Mendeli* is a somewhat variable plant as regards colour, but in all forms it is extremely beautiful; indeed, it may be considered to be one of the best of *Cattleyas*. Its flowers measure from 6 inches to 8 inches across; the sepals and petals are white, or blush-white, suffused with pink, and the lip is large, and more or less magenta or magenta-purple. In April the two kinds just named will still remain in flower and be supplemented by *C. Skinneri*, which produces from five to ten rich, clear, rosy purple flowers on a spike. In May we have *C. Mossiae*, *C. intermedia*, and *C. Leopoldi*. Of these the first bears from three to four flowers upon a spike, each bloom measuring about 6 inches across; sepals and petals pinkish; lip crimson or purplish crimson. In *C. intermedia* the flowers are not so large, but they are numerous; the sepals and petals in this case are white, tinged with rose, and the lip is deep rosy purple. *C. Leopoldi* produces many flowers on a spike; the sepals and petals in this species are yellow, flushed with green and dotted with crimson, the lip being white and purple. In June, in addition to the last-named kinds, we have *C. Warneri*, a kind with flowers measuring upwards of 6 inches across; their sepals and petals are deep rose; the lip intense deep crimson, and beautifully frilled on the edge. This will continue well into July, when *C. crispa* and *C. Harrisoniana violacea* will maintain the display. *C. crispa* bears from three to five flowers on a spike; the sepals and petals are white, and the lip, which is also white and deep crimson in front, is much crisped or curled on the edge. In *C. Harrisoniana violacea* the sepals and petals are soft violet, the lip being a deeper shade of the same hue, with a stain of yellow on the front lobe. In August comes *C. Gaskelliana*, a very variable plant as regards growth; the flowers of the type are large, and their sepals and petals are rosy lilac, the lip being blotched with orange or yellow. *C. Dowiana aurea*, which also flowers this month, has golden-coloured sepals and petals, and a very large lip which is velvety purple, flushed with crimson, and beautifully veined with lines of gold. *C. labiata pallida* has pink sepals and petals, and a purplish crimson fringed lip. In September some of last month's flowers will still be in good condition, and to them may be added *C. bicolor* and *C. Eldorado*. The first, a tall, slender-growing plant, bears on a spike many flowers, the sepals and petals of which are coppery green; the lip is rosy purple edged with white. The sepals and petals of *C. Eldorado* are pale pink with a deep orange and purple lip; these two plants will keep in flower until October, and will be succeeded by *C. Harrisoniana violacea*, a variety which produces a second crop of blooms on the young growth made since August. In November *C. maxima* comes into bloom; its flowers, eight or ten on a spike, are bright rose, more or less heavily veined in the lip with crimson. With this may be associated *C. guttata*

with its many-flowered spike of flowers, the sepals and petals of which are greenish yellow dotted with red; the lip is white, flaked with purple. Both these sorts will continue into December, by which time *C. Trianae* will be ready to again come into bloom, and also the variety *delicata*, in which the flowers are white faintly tinged with blush and stained in the throat with yellow. There are many other beautiful species and varieties of *Cattleyas*, but the above will be found a good selection to start with, and if success is obtained in their culture, choicer kinds may be added at pleasure.

These *Cattleyas* are, with but one or two exceptions, profuse blooming kinds, and may be grown in pots or baskets as shown in the annexed illustration. An intermediate house suits them best—that is to say, a temperature which does not

or they may become permanently disfigured. *Cattleyas* do not require much water at their roots, but a genial moisture should always be kept rising between and through the plants. When growth is finished they should be kept somewhat drier, but never so dry as to cause shrivelling of the pseudo-bulbs. When the flowers begin to push through the sheath the plant should be watered freely, for if starved at that particular time the blooms are apt to open either small or deformed. Plants belonging to this genus do not like much soil about their roots; the pots in which they are placed should be drained in such a manner as to remain in working order for two or three years, and the compost should consist of fibrous peat from which all fine particles have been shaken, some nodules of charcoal, and Sphagnum or wood Moss; the

Cattleya Trianae.

fall below 60° at night, and rises during the day some few degrees higher. In summer the night temperature should not fall lower than 65°; an abundant supply of air should be freely admitted whenever possible, but cold draughts must be avoided, and a moderate amount only of moisture should be kept in the atmosphere. *Cattleyas* grow naturally upon the exposed branches of trees and upon rocks, a sure indication that they enjoy strong light; consequently they should be placed near the glass, and shading should be resorted to only during the hottest part of the day; it must never be forgotten, however, that the action of the sun's rays upon the foliage under glass is very different from what it is in the open air; therefore under glass the leaves should never be wet when exposed to sunshine,

latter will be found equally as good as Sphagnum for mixing with the peat. Plants at rest should be kept at the coolest end of the house.

***Cattleya Trianae* at St. Albans.**—This *Cattleya*, like the majority of plants that exist in widely distant localities, varies considerably in the colours and markings of its flowers; indeed, no two separate plants can be found to produce flowers exactly alike. It is a robust and free-growing kind, and generally begins to open its blooms about Christmas or early in the new year. *Cattleyas* indeed, if properly selected, can be had in flower all the year round, and they are, moreover, especially manageable even under Vines if these are kept properly stopped and thinned, so that they do not unduly monopolise the light. *C. Trianae* produces large flowers, which range in

colour from the purest white (which is even now extremely rare) through all shades of blush, mauve, lilac, rose, and purple to rich crimson, and hundreds of its gorgeous blooms are now to be seen at Mr. Sander's nursery, St. Albans.

Odontoglossum blandum.—This is by no means a common species in our collections, being very difficult to import alive; even in its native country it is not plentiful. It is found in very moist forests in New Grenada at an elevation of from 6000 to 7000 feet; consequently it requires to be kept both cool and very wet. At first sight it reminds one of *O. navium*, from which, however, it is very distinct. The spike is nodding, dense, and the flowers have a sweet perfume, somewhat resembling that of honey. The sepals and petals are pointed, white, and spotted with reddish purple; the lip, which has a spreading front lobe, tapers to a point, and is serrate at the edges. It is white, spotted sparsely with reddish purple near the base, and more or less dotted with the same colour in front. We recently saw this beautiful form in Mr. Measures's garden at The Woodlands, Streatham.

Cypripediums at Cambridge Lodge.—This genus is a specialty with Mr. Measures at Cambridge Lodge, Camberwell, and is represented by nearly a hundred and seventy species, varieties, and hybrids in luxuriant health, many of them possessing such strikingly handsome foliage, that flowers are scarcely necessary, so great is its beauty. Amongst the many fine forms, however, which are now in bloom we specially noted *C. Meirax*, with vinous purple flowers; a very fine form of *C. nanthum superbum*, in which the whole flower is richly suffused with crimson; a distinct form of the rare *Cypripedium Sallieri*, and a remarkable variety of *insigne* called *grande*, in which the dorsal sepal is large, and even whiter than in *Cypripedium Maulei*; another beautiful variety of the *insigne* type is *Richardi*, which, in addition to its other attractions, has the petals streaked and blotched with violet. *C. Williamsianum* is a very handsome cross between *C. villosum* and *C. Harrisianum* (the latter itself a hybrid); the peculiar markings of the leaves of this variety are perpetuated, whilst the flower is a happy combination of the colours of the parents. *C. melanophthalmum* is a pretty plant, the ruling colour in its flowers being Indian purple; *C. Haynaldianum*, which may with propriety be styled the winter-flowering *Cypripedium Lowi*, and many others are all here.

Moth Orchids (Phalæopsis) at Clapton.—Amongst the enormous quantities of Orchids in Mr. Low's nursery, at Clapton, especially noticeable at the present time is the great houseful of *Phalæopsis*, where thousands of spikes are just unfolding their buds, and, in the event of the weather being bright during the next fortnight, they will present a sight which has seldom been equalled in this country, as by that time many thousands of flowers will be open which at present are undeveloped. In looking over these plants it is no easy task to decide which is the fairest, as they each and all present so many charms to the eye. Of kinds expanded we noted *P. Stuartiana*, of which there are innumerable forms. The leaves when young are marked and streaked with silvery grey, but become almost plain when mature. The flowers are borne upon much-branched panicles; the upper sepal is white, the lower ones white or creamy white, dotted and freckled with cinnamon or chestnut, the markings varying much in density in the different plants. The central part of the lip is marked similarly to the lateral sepals, the margins and the recurved horns being white. *P. Schilleriana* is now well known for its beautifully marbled and transversely banded leaves, but with the return of each flowering season it appears to reveal fresh beauties. Amongst the numbers now flowering with Mr. Low it is not surprising that distinct varieties have appeared from those having flowers with deep mauve-coloured sepals and petals, through all shades to almost pure white; the mauve lip, ornamented in front with two recurved points resembling buffalo horns, is more or less spotted with reddish purple and stained with yellow. Another kind is *P. leucorrhoda*, which would appear to be a

hybrid between *P. amabilis* and *P. Schilleriana*. The leaves of this are marbled, but in a less degree than those of *Schilleriana*, whilst the beauties of both flowers are charmingly blended. *P. rosea*, although one of the smaller-flowered kinds, is a most desirable species, especially on account of the profuse way in which the blooms are produced, combined with the great length of time during which they continue in perfection. *P. Sanderiana*, now also open, appears to be another variety raised between *P. amabilis* and *P. Schilleriana*, the beauties of the two commingling and producing a totally distinct flower from that of *P. leucorrhoda*. In *P. Sanderiana* the sepals and petals are white suffused with a charming tinge of rose, whilst the lip is more or less marked with purple and yellow. The large snowy-white flowers of *P. amabilis* and *P. grandiflora*, the lip of the former being stained inside with rosy pink and purple, and that of the latter yellow or orange, are also opening in countless numbers, and go to make up a display which will amply repay a long journey to see.

SHORT NOTES.—ORCHIDS.

Cattleya bicolor.—From Mr. Marriott come flowers of a magnificent variety of this fine old species, large masses of which are flowering in his Edmonton nursery; the rich deep, rosy plum-coloured lip, having a broad marginal border of pure white, renders this *Cattleya* very effective.

Lælia alba.—This charming plant is now flowering freely in various nurseries round London, notably in those of Mr. Williams at Holloway, Mr. Bell at Chelsea, Mr. Lang at Forest Hill, Mr. Shuttleworth at Clapham, and Messrs. Horsman at Colechester. We would specially direct attention to the fact that it, and also various other Mexican kinds, such as *L. anceps* and *autumnalis*, grow and flower well if superceded in a sunny window.

Lælia flava.—This brilliant-coloured species is now in bloom in Mr. Measures's garden at Streatham, the brightness and distinctness of its flowers rendering it very conspicuous. It is a dwarf-growing plant, bearing upon a rather long scape a dense head of brilliant yellow flowers, the front lobes of the lips of which are heavily fringed.

Saccolabium bellinum.—This small-growing variety belongs to the same section as *Saccolabium eucoloræ*. The sepals and petals are pale yellow, irregularly blotched with blackish brown; lip pouched, white, with a large flat-spreading middle lobe, which is beautifully spotted with purple; disc yellow, dotted with red; edges prettily fringed. This is a Burmese species, which we recently saw in Mr. Southgate's choice collection at Streatham.

Pilumna nobilis.—This plant belongs to a small family which is closely related to the *Trichopogonias*. It is a dwarf plant of easy culture, and its fragrant blooms are produced freely during winter and early spring. The sepals and petals are pure white, as also the lip, which is stained in the throat with an eye-like spot of deep orange. We saw this recently in great profusion with Mr. Sander in his nursery at St. Albans.

Odontoglossum Ruckerianum.—This is considered to be a hybrid, *O. crispum* being one of its parents; its flowers are paniculate; the sepals and petals white, faintly suffused with blush on the margins, and spotted with chocolate-brown; lip creamy yellow, blotched with chestnut. This is said to be an early summer bloomer, but we saw it with Mr. Measures at Cambridge Lodge, Camberwell, early in February, where it had then been in full beauty for upwards of a month.

Cattleya Trianae (P. J.).—The *Cattleya* sent is one of the many forms of the variable *C. Trianae*, and is often named *alba*, which is misleading, the albivariety being pure snowy-white, with a slight stain of yellow in the throat. There are plenty of plants that produce white sepals and petals, and the lip is also white when it first appears; but in the course of a few days the front portion becomes suffused with pale mauve or blue, as in the flower you send, which is a good form, but not the *alba* variety.

Odontoglossum coronarium.—We recently saw this plant in bloom with Mr. Measures at The Woodlands, Streatham, under the name of *Odontoglossum brevifidulum*, a mistake we invariably see made in gardens. The flowers are produced from the pseudo-bulbs when just mature, and measure some 2 inches or $2\frac{1}{2}$ inches across, having the appearance of being varnished; sepals and petals reddish brown, with narrow yellow border, slightly serrated lip, with a spoon-shaped blade, bright yellow.

Cologyne cristata Lemoniana.—A well-grown plant of this lovely orchid now bears upwards of forty spikes of snowy blossoms in the gardens at Straffan, Co. Kildare. As this seed strong and healthy and laden with its pendant sprays, there are but few Orchids more beautiful at this season. At Mount Merrion there are several good and well-flowered plants of the typical *C. cristata* with large egg-shaped bulbs and a profusion of flowers. So fine are they, that they remind one of the Chatsworth and Bowden specimens of years ago.

Lycaste Skinneri.—These are largely grown by Mr. Sander at St. Albans in suspended baskets, in which position they show even to more advantage than in pots. Baskets full of these plants, bearing scores of bloom, have been conspicuous in the cool houses for upwards of a month, and yet to all appearance they are as firm and fresh as if they only opened yesterday. The ease with which these plants

may be grown, the great variety in their colours, and the length of time during which the flowers remain in good condition cannot be too strongly impressed upon the attention of our readers.

Orchid culture.—The arguments brought forward to prove that trade in Orchids is thriving are somewhat amusing. I have said that Orchid culture is on the wane, and given evidence to that effect, but the best evidence on that head is that furnished by "T. B." "At one time," he says, "desirable kinds realised more pounds than they now do shillings," and although this is given as a proof that trade in them is increasing, no one will accept that view. It would be the first time in the history of trade that a steady reduction in prices indicated a brisk business in anything. No doubt extensive importations have helped to bring this about, but the fall to shillings from pounds in price shows that the supply exceeds the demand by a hundred per cent., and that is exactly what Orchid dealers say. "T. B." has clearly not reckoned the significance of his admission on this head. Another cause of low prices is the numbers of private collections that have been thrown back upon the market of late years. I am not striving to render Orchid culture unpopular, but only stating facts. When purchasers disappear, trade is on the wane; and who, knowing the unparalleled reductions that have taken place in gardens all over the country lately, can pretend to say that the culture of the most expensive plants in the garden is on the increase. I could record facts that would demolish "T. B.'s" figures if I was at liberty to mention names. One private grower seeking a purchaser for his collection, consisting wholly of fine plants in good health, was obliged at last to part with them for about one-tenth of what they had cost him, and only one party could be induced to take them on these terms. Another grower parted with a similar collection on similar terms after offering his plants privately to reputed Orchid fanciers, none of whom were, however, buyers. A third grower, one of the best known, parted with a large collection of grand plants on equally easy terms.—W.

SEASONABLE NOTES ON ORCHIDS.

WHEN February comes in Orchid-growers carefully look over their collections, and every plant that ought to be repotted is seen to at once. Some may not require repotting, but they will need surface-dressing. During winter they will have been kept comparatively dry at the roots, and the Sphagnum dies; therefore, now that growth has in most cases begun, a little fibrous peat and some live Sphagnum pressed on to it will cause a mass of healthy roots to push over and into it. We began with cool Orchids; the first operation was to carefully sponge the leaves from dust, and to brush off any greenfly hanging upon the flower-spikes. When this was done the plants were ready for repotting or surface-dressing. Except in very exceptional cases, none of them are repotted in autumn, as they have to be kept comparatively dry at the roots, and in a dry atmosphere subsequently, which causes the Moss on the surface to die, and the plants must have a surface-dressing in spring. Many repot their *Odontoglossums* in autumn, and some continue the work through the winter. We are now repotting most of ours; the roots are not disturbed more than is necessary. Their state in the different specimens varies a good deal, being healthy in one case and in another decayed. Plants that have healthy roots will be repotted into larger pots. The others will have all decayed roots, and their surrounding compost removed and be repotted in pots one, or even two, sizes smaller than those in which they were previously. If the case is a bad one, the old potting material is washed off with rain-water, the roots are shaken dry, and the plant is at once repotted. We fill the pot half full of clean potsherds arranged very loosely, and the plant is potted firmly in the usual Orchid compound of fibrous turf, Sphagnum, and broken potsherds. These remarks apply to most of the *Odontoglossums* and *Masdevallias* of the M. Harryana, M. Veitchi, and

M. ignea types. Some species of valuable cool-house Orchids, such as *Oncidium maeranthum*, *O. Marshallianum*, and other *Oncidis* of this class, which push their roots more out of, than into the potting soil, require more careful handling. The last-named species does best in baskets suspended near the roof of the cool house. Under these circumstances, the roots twist out and in around the teak rods. *O. maeranthum* does well in pots, but it is best not to disturb it too often. Repotting once in two or three years will be sufficient. When repotted or surface-dressed the surface must be regularly watered with rain-water to encourage the emission of roots near the surface, and to keep the Moss in a healthy growing condition.

CATTLEYA HOUSE.—Inmates of this house should be attended to at the end of the month and in March. The handsome *Cymbidium eburneum* is pushing up its flower-spikes freely. We generally pot *Cymbidiums* in May once in two years. They have been surface dressed with turfy loam and decayed manure, for in potting or surfacing these we use very little or no peat in the soil. *C. Lowianum* requires much the same treatment. *Cologyne eristata* is also coming freely into flower, and at this time a little weak manure water applied to the roots is a useful stimulant. *C. Massangeana* and *C. barbata* are now pushing up their new growths; indeed I have potted these in peat and Sphagnum. *Aerides* also ought to be seen to as well as *Vandas* that succeed best in this house; all are grown in pots, as they are more convenient than baskets. These are filled up to two-thirds of their depth with clean drainage, and on the top are placed some Sphagnum and drainage in about equal proportions. *Vanda cerulea* has not yet been repotted. It seems to be quite at rest, so far as one can judge by the appearance of the roots. It does not take to pot culture so readily as the *V. suavis* and *V. tricolor* type do. We have always had the greatest success with it when potted in teak cylinders three-parts full of drainage. The cylinders become firmly interlaced with roots, which are also coiled round the insides of the pots. Rather than disturb these roots we merely remove the Moss from the surface and replace it with fresh material when the plants appear to be starting into growth. After that both Moss and roots are kept comparatively moist. *Cattleyas* are all pushing growths in various stages of development, and over-dryness would probably give them a check; but, on the other hand, watering them too freely might be even more injurious. A large specimen *Cattleya* might not require to be watered more than once in two or three weeks, even in the growing season, and much will depend upon the character of the material in which it is potted, and also as to its depth. Some give a greater depth of potting material than others.

IN THE EAST INDIAN HOUSE plants of *Odontoglossum Roczi* are throwing up their flower-spikes, and it is as well to look over them carefully with a lamp at night to prevent them from being injured by slugs, &c. I am inclined to attribute any success we have had in the culture of these plants to keeping the leaves quite clean by dipping them in tobacco liquor and keeping them in a minimum winter temperature of 60°. They are also repotted in June or July when the flowering period is quite over. *Oncidium ampliatum majus* has now pushed up a plentiful supply of flower-spikes. Slugs attack these most persistently when just pushing out from the sides of the bulbs, and destroy great numbers of them. These plants require to be placed at the warmest end of the house, and to be plentifully supplied with water when making their growth, and even when at rest water must not be withheld to the same extent as may be deemed essential to the well-being of some species of *Oncidium*. Plants of *C. gigas*, *C. Dowiana*, and others of this type have been kept in the *Cattleya* house in a comparatively dry state; they have not shown as yet any signs of growth, but as soon as they do so they will be placed in the warmest house quite close to the glass, and will also receive a good

supply of water at the roots. I fancy that all Orchids kept in quite a dry state at the roots during winter may be more freely watered after the resting period is over than others not so treated. The very remarkable *Cologyne pandurata* is a plant that ought to find a place in every warm house, and as it has been imported rather plentifully during the past year, many may be glad to know that it succeeds best in the warm house, and the best time to repot it is when the flowering period is over. Large specimens occupy a considerable space, and it is probably not adapted for culture in small houses; but the green and black flowers of large size produced on vigorous spikes are very remarkable. The handsome *Oncidium Lanceanum* succeeds best suspended close to the roof and grown in teak baskets. As the season advances and the leaves feel hot to the hand during sunshine, it is best to place it on the stage, hanging it up close to the glass again in winter. It ought not to be much disturbed at the roots; I would rather pick out any decayed material and replace it with fresh than turn the plant out altogether. The plants of this and other kindred species, such as *O. hamatophilum*, are now starting into growth, and require more water than they have hitherto had.

J. DOUGLAS.

NOTES OF THE WEEK.

The Crystal Palace exhibitions of plants, flowers, and fruit to be held during this year are as follows: Spring exhibition, March 26; great summer exhibition, May 21; Rose exhibition, July 2; fruit and National Dahlia show, September 2 and 3; great autumn fruit show, October 6 to 8 inclusive; and Chrysanthemum exhibition, November 4 and 5.

Royal Horticultural Society.—A special meeting of the council of this society has been summoned for Tuesday, the 22nd inst., when part of the business will be to appoint a sub-committee of the council to confer with the committee nominated at the annual general meeting to consider the future of the society's affairs. The following dates have been fixed for the meetings of the Narcissus committee, viz, March 22, April 12 and 26. Should the season be backward, it may be found desirable to hold another meeting on May 10.

The London parks.—According to the Public Parks and Works Metropolis Bill, it is proposed to transfer on the 1st October, 1887, the following parks and places, viz, Victoria, Battersea, Kennington, Bethnal Green, and Westminster Bridge, to the jurisdiction of the Metropolitan Board of Works, who are to maintain them, such maintenance (as far as is not met out of the income of properties transferred with the above places) to be paid out of the consolidated rate, and no part of the metropolis to be exempt from whatever rate may be levied for such maintenance.

Spring flowers in the Isle of Wight.—I send you a few spring flowers which have not appeared in your lists. Their names are as follows: *Colchicum luteum*, *C. vernum*, *Leontice Alberti*, *Iris Sophronitis*, *Muscari lingulatum*, *Helleborus colchicus formosus*, *Crocus Sieberi* and *C. damascenus*. The yellow *Colchicum* is a very pretty flower, and does not belie its name. The *Leontice* is closely related to *Bongardia Rauwolfi*, which Mr. Elwes declares to be "so choice, that no garden should ever be without it." I am indebted to the kindness of Prof. Foster for *Iris Sophronitis*, which is a most valuable little possession, as it bridges over the comparatively dead time of the year just before *Iris reticulata* makes its appearance. I plucked the first blossom of *Iris reticulata* in the open ground yesterday, which I send to you; it is just in time to shake hands with *Iris Sophronitis* before the latter disappears from the scene. *Anemone blanda* is an old friend, and not at all behindhand this spring. *Muscari lingulatum* came to me from Herr Max Leichtlin, and is certainly both precocious and very pretty. I wonder why *Niphion Histro* is not much more generally known than it is. It is invaluable during the winter months, and astonishes the beholder who sees it for the first time. Mr. George Paul seems to get on very well with it at Broxbourne, and it would, I think, do well any-

where in a light sandy soil. I have come to think that it seeds over my borders, as I have some flowering bulbs this year in places and patterns which neither I nor my gardener would have chosen for them. *Helleborus colchicus formosus* is one of the handsomest varieties I have ever seen of this delightful Hellebore. A whole array of Christmas Roses are in blossom here now, but I will not trouble you with their names. Of the Snowdrops mentioned by Mr. Webster, I cannot understand why *Galanthus latifolius* is so much later here than with him. I have no sign of bloom yet; all the rest are in blossom or they will be so in the course of a day or two. *Galanthus virens* was most kindly given to me by Mr. Allen. If fogs and snow still hang over the regions about London, it must be some consolation to you to know that in two or three weeks' time you will be as we are now. Though east winds still prevail, I can safely tell you that, so far as flowers are concerned, the winter is over and gone.—H. EWBANK.

National Chrysanthemum Society.—On Monday evening last the new floral committee of this society was elected, and the dates of meetings were arranged as follows: October 12 and 26, Nov. 9 and 23, Dec. 7. The society's exhibitions of early flowering varieties will be held on Sept. 14 and 15, the November show on Nov. 9 and 10, and that for late-flowering Chrysanthemums on Jan. 11 and 12, 1888. The new schedule was then submitted for the consideration of the committee, and various rules and regulations altered and amended.

Erythrina marmorata.—Unlike the common Coral plant and its varieties, this requires stove temperature all the year round, but under that treatment it is undoubtedly a free-growing kind. It is a plant of erect habit, shrubby in appearance, and has brightly-coloured variegated leaves, which, although of the same form as those of other kinds, are much broader. Their ground colour is dark green, heavily blotched and spotted with creamy white, the two colours forming an agreeable contrast. It was introduced, we believe, from the South Sea Islands some ten years ago, and since then its elegant and cheerful aspect has been noticed favourably on several occasions. Unfortunately, it is deciduous, remaining leafless during the winter months, and in that state it is now in flower in Messrs. Veitch's nursery at Chelsea, a small plant only a few inches high bearing one spike, consisting of about a dozen flowers, which, though smaller than those of the *Erythrina Cristagalli*, are disposed in the same way, and, indeed, are equal in brilliancy to those of a *Vesuvius Pelargonium*. If full-grown plants produce flowers in comparison to their size, it will prove to be one of the best plants which we have of recent introduction.—G.

Violets (A. D. P.).—The varieties sent are very fine flowers of their respective kinds.

Stephanotis (J. B.).—This occasionally produces fruits, but we do not remember to have heard of their ripening in this country.

Old yellow Rose.—If "F. W. Y." cannot obtain *Rosa sulphurea* at Rodger, McCalland's, of Newry, by next autumn, I will give "F. W. Y." a cutting of my plant.—FRANK MILES, *Shirchampton, Bristol.*

Narcissus seed.—Mr. Barr, King Street, Covent Garden, desires us to state that he has a quantity of *Narcissus* seed which he will be happy to distribute in small packets to anyone who cares to apply for them, and who will send their name and address on a stamped envelope. It should be sown, he says, where it can remain undisturbed till the bulbs get to flowering size.

Names of plants.—*A. Chelidonium.*—You *Cattleya Trianae* is an ordinary form only, but very handsome; *Odontoglossum Rossi majus*, good form; *Laelia anceps*, typical form; *Dendrobium Wardianum*, will probably improve.—*J. B., Rochester.*—Send leaf or specimen.—*G. S. B., Weybridge.*—*Cryptomeria elegans.*—*Falcata* 1, *Dendrobium Pierardi* 2, *Chelidonium elegans*; Orchids should be gathered when their growth is completed.—*G. B., Dunfermline.*—*Odontoglossum triumphans*, *Cypripedium venustum*, *Oncidium maculatum*; we cannot say where seeds of *Ambonia fragrans* can be obtained, but should think large seed firms could supply you.—*E. H. S.*—*Eupatorium riparium*, *Rhynchospermum jasminoides*; greenhouse.—*Leiberg.*—*Onoplosides verna*—*J. S., Cornforth.*—*Reineckia carnea.*—*Rondeletia.*—1, *Scleria aurea*; 2, *Eriola glauca*; 3, *E. sp.*; 4, *E. comosa* var.; 5, *E. campanulata*; 6, *E. lutea*; 7, *E. urceolata*; 8, *E. brunneata*; 9, *E. albicoma*; 10, *E. Monsoniana*; 11, *E. sp.* Will the sender of these specimens state in what district, and by whom they were collected? Seeds of 2, 5, 6, 7, 9, 10, and, indeed, of almost any of these *Eriolas*, would be acceptable.—*J. M.*—Without flowers we cannot name your *Araca*.

WOODS & FORESTS.

"YORKSHIREMAN."

WOODS THAT PAY.

AFTER all is said and done, I think it can be shown that the reason why English woods do not pay in these days is not because of the cost of management and culture on the whole, but because of the poverty of our woods in the matter of saleable timber of the right sort and size. Estates generally are greatly deficient in quantity and quality of timber. The ground planted has not been planted with the right sort of trees, and has not been allowed to produce as good a crop as it might have done. In the colliery districts of England foreign prop-wood is delivered in millions of feet annually at about as low a price as it is ever likely to reach, to the almost total exclusion of English timber, but low as the price is it would have paid any estate near these districts to produce the same kind of timber; $\frac{1}{2}$ -inch to 6-inch prop-wood, such as is used, could be grown here at the rate of about 5000 feet to the acre, which at 5d. per foot in the wood would give a return of from £2 to £3 per acre. I see no difficulty whatever to produce colliery poles of Larch at that rate, and I am estimating at the price of foreign Spruce poles as delivered here, which are inferior to Larch, and can seldom be used more than once, as they give way at the ends or in the middle. Corsican Fir would return even more. This is allowing room to grow poles 6 inches square in forty or fifty years or less time, according to the land. Spruces that I assisted to plant less than forty years ago in Scotland now girth more than that, but having been too freely thinned out have too many branches and knots for colliery purposes, and are useless for anything else. Of all the fallacies ever taught on the subject of forestry, that which inculcates giving timber trees room to produce more than a fair top only of branches is the worst, and it is a fallacy that has been freely acted upon. For those who are prepared to plant Ash, Sycamore, and Corsican Fir extensively, and to grow it as thickly on the ground as it should be grown, there is yet prospect of remuneration to themselves or their children, and the man who now plants freely and in proportion can afford to turn his mature crops into money at the same time. This is the right way to regard estate forestry at the present time. Fell what is ready for the axe and plant in proportion. This would give a good income from the wood and provide a future supply of timber; and after all, thriving young plantations are just as good to look upon as old ones, not to speak of woods that are both old and useless. Money without end has been lost on estates through neglect to fell and sell timber when it was good and in demand, and to plant an equivalent. On every well-managed estate there should be crops of trees of all ages and sizes, and a complete succession of crops regularly kept up, and so provide a regular return without impoverishing the estate.

Pinus rigida.—Mr. Webster's impression (p. 158) that this Pine will not succeed by the seacoast would be removed were he to see how it grows along the whole line of the south coast, where it stands better than most other Pines. He may see fine trees of it in the various arboretums from Devonshire to Sussex and the Isle of Wight, while a little way inland it thrives on the most exposed places. As to the composition of the soil it grows best in by the sea, I cannot inform Mr. Webster, as it never occurred to me that such a hardy Pine as *P. rigida* refused to grow in any ordinary soil; nor does it, as far as my experience goes. As regards the illustration given in THE GARDEN, which Mr. Webster criticises, I contend that it represents the tree well as far as the outline and

branching go, though it may not be the best example of the engraver's art. I see this Pine perhaps not "day by day" (as Mr. Webster says he does), but often, and not merely in one place, but in various parts of the country in old arboretums where it has developed its true growth, and I am well acquainted with the tree's peculiarities. Minute details as to the wings of the seeds being a fiftieth of an inch broader or narrower, or the cones being larger or smaller, are matters more for botanists than foresters, for whom we write. Mr. Webster has come to the conclusion that a good deal of the knowledge derived from books is faulty in the extreme. I grant this, but from what source did he get his? Life is too short to begin at the beginning of such a wide subject as trees, and not avail ourselves of what others have done for us. There is faulty information in books certainly, and in old ones this must necessarily be so, but it is only by comparing the observations of others with our own that we can hope to get knowledge on such wide subjects as gardening and forestry. There is happily a good storehouse of information about trees, which in the main is as true now as when written fifty years ago. We have to add to this knowledge, and the more we endeavour to do so, the less danger is there that we will look at things in a narrow-minded kind of way.—W. G.

COST OF RAISING FOREST TREES.

AMONG the various arguments that have been advanced in favour of planting, there is a rather important one not yet touched upon, and that is, the reasonable prices at which forest trees can in these times be obtained from public nurseries. As most readers will know, nursery stock, at least the forest tree department, increases in value until it is four or five years old, and if not disposed of then, it must be pulled up and burned. In dull times, such as those we have passed through during the last few years, a large proportion of the nurseryman's profit has been swallowed up in this way. It is not easy for those who have no experience of the cost attending the rearing of forest trees for the first four or five years to realise the expense and risk incidental to it. Take, for example, a crop of Larch. I shall suppose the seed to have been sown in May, 1885, and to have produced a good crop of healthy one-year seedlings which would last autumn be worth from 2s. to 3s. per 1000. Instead, however, of clearing them off during last winter or spring, suppose it was determined to leave them another year in the beds, they might then be expected to be worth 5s. per 1000 in the trade, or from 6s. 6d. to 7s. 6d. retail. But the temperature falls a few degrees below the freezing point in the end of April or in May, as it did last spring, nips the tender tops of the seedlings, and the nurseryman's hopes are blasted, so far as these are concerned. It is, however, a very much more serious matter when seedlings that have been planted out and grown in nursery lines for three or four years have to be burned on account of there being no demand for them. The expense incurred in the rearing of them is very considerable. In the first place, there is, as we have seen, the cost of the seedlings, then there is the rent of the land, which in different parts of the country varies from £5 to £12 per acre, the manure which will cost from £5 to £6 per acre, the cost of planting say 9d. to 1s. per 1000, the weeding, which will cost about £5 per acre, at least during each of the first two years after transplanting. If, then, after all this expense has been incurred the trees cannot be disposed of, but have to be burned, as many hundreds of thousands have had to be during the last two or three years, there still remains to be added the cost of the burning. This may be thought to be an insignificant item, but when I mention that I know one nurseryman who last winter paid £40 in wages for the mere pulling up and burning of unsaleable stock it will be admitted that it is an item not to be altogether ignored. I know also that the nurseryman I allude to had to purchase a portion of that stock as seedlings some four years ago at 4s. per thousand, from which fact the inference may fairly be drawn that the farmers have not a monopoly of hard times. The natural consequence of this is that nurserymen are, as a rule, curtailing their stock of forest trees, and I do not

think I am exaggerating when I state that there are at least 200 acres less of land under nursery crop in Scotland alone than there was five years ago. On the not extravagant computation that an acre should produce 100,000, this represents 20,000,000, which, at 3½ feet apart, would plant 5264 acres. The quantity of nursery stock that has been in recent years sold by auction is also a pretty clear indication that the supply has been considerably in excess of the demand. The moral to be drawn from all this seems to be that the nurseryman's necessity is the planter's opportunity. N.

THE LARGE-CONED PINE.

(PINUS MACROCARPA.)

IF only for its remarkable cone, this Pine is well worthy of attention, for certainly in the specimen before me its huge size and pretty colour are not surpassed by those of any other species with which I have come in contact, or had the opportunity of examining. That it is a tree in every way well adapted for planting in this country I need only refer your readers to the noble specimens at Bayfordbury, Knap Hill, Pampesford, Kew, and many other places we know of; yet for all this, and considering that it has been introduced to us for upwards of half a century, few indeed, save in the collections of connoisseurs, are the trees to be met with, even at the present day. Scarcity and the high price of young trees may to some extent account for the absence of this Pine in our woodlands, or it may be that its hardihood and value in an ornamental and commercial sense are not so well known as the merits of the tree entitle them to be. It grows well in a variety of soils, as has been proved in this country, that of a limy or chalky nature having, however, preference for its particular wants; but on the London clay it is one of the few trees that really do well, while in good dampish loam and in a free, sandy soil we have likewise found it to grow in a fairly satisfactory manner. As to whether or not well-reclaimed peat—that specific for most miffy Conifers—will sustain and bring to perfection specimens of *Pinus macrocarpa*, I am, unfortunately, not in a position at present to state; but that young trees have survived and flourished in such a soil for a considerable length of time may be made mention of.

Speaking widely, or rather as a casual observer, I might say that in appearance *Pinus macrocarpa* approaches very nearly to *P. Sabina*, but is usually in young trees not so crooked in growth, and of a more pleasant green tinge in the foliage. The leaves are usually arranged in threes (this is, however, not always the case, for on the same tree we have found them in fours and in fives), 10 inches long, stiffish, rounded on the outside, and sharp-pointed. The cone now before me is conical-oblong, hard as a piece of carved work, and of a pleasant yellowish brown colour. It is 8 inches long, by fully 5 inches in diameter at the base, and weighs about 2 lbs.—small certainly when compared with the four-"pounders" and 12-inch-long specimens said to be found in its native wilds. The footstalk is 1½ inches in length, by three quarters of an inch in diameter; while the scales of the cone, which are much hooked, are fully 1½ inches wide, as seen in the unbroken specimen. Seeds, wing and all, 1 inch long—not large, comparatively speaking, and of a colour almost approaching the surface of the cone.

The nursery management of *Pinus macrocarpa* is simple enough, for I am informed by a continental friend who has raised it in some quantity that in their younger stages seedling plants are stout of growth and robust in constitution, and may be planted out permanently at an earlier stage than almost any other Pine. The seeds are heavy and with an unusually

hard outer coating, only 1360 being included in a pound weight, while of other Pine seeds—take, for example, *P. Laricio*—no less than fully 43,000 are required to turn the same scale. Like the *Pinus Laricio*, *P. macrocarpa* produces a strong tap root or usually two or three stout roots, and is, unless frequently transplanted, wanting to a great extent in the numerous fibrous rootlets that are so valuable an adjunct to young trees of the Pine tribe when planted out permanently. Plenty of room for perfect development should be allowed to this tree when planted out, more particularly where a well-furnished standard specimen is required, for when grown in a confined situation the usually tufted foliage and bare branches, which, by-the-bye, are not very ornamental features of the tree even when in the best of health, are rendered conspicuously ugly, and remind us much of the appearance, wretched in the extreme, of an ill-grown specimen of *P. ponderosa*. Our largest tree has a north-eastern aspect, is growing in loamy leaf-mould, and sends its roots far in amongst the broken, shingly rock that crops out every here and there through the woodland in which it is planted. It is in perfect health, but I do not class it as even second-rate amongst the Pines as an ornamental tree, although its distinct tufted or massy glaucous foliage and pretty warm brown bark, which is well set off between the widely-placed whorls of branches, have peculiar charms for the lover of our Pines in general.

In this country the growth of *Pinus macrocarpa* is not by any means slow, for a tree at Bayfordbury planted in 1845 was in 1885 39 feet in height and 6 feet 6 inches in girth of stem at a yard from the ground, while another that was brought under my notice recently, is now fully 10 feet in circumference, although only planted in 1839. A section of the wood of English growth in the Royal Horticultural Society's garden is fully a foot in diameter, and shows from its wide annual rings that the tree which produced it must have been quite at home in Surrey. At Blenheim, Dropmore, Castle Ashby and Nettlecombe, as well as the various places before mentioned, there are goodly specimens of the Pine in question. In company with *Pinus Lambertiana*, *P. macrocarpa* inhabits, in fair abundance, a few of the high-lying Californian mountain chains, notably Santa Lucia, where it was discovered by Dr. Coulter and named, in compliment to him by Professor Don, *P. Coulteri*, a name which, so far as we can trace, has priority of right over that of *P. macrocarpa* given by Lindley.

A. D. WEBSTER.

VARIOUS SYSTEMS OF PLANTING.

THE serious havoc sometimes made by storms in artificially formed plantations is so disheartening to proprietors, that we may well pause, and ask, Can nothing be done to remedy this state of things? In the formation of young plantations three different systems are practised; first, by sowing the seeds; second, by slit or notch planting; and third, by pit planting.

THE SOWING SYSTEM.—This, the natural method, is best adapted for heather moor, bare wind-swept hill-sides, and barren peat bogs. By this system the trees are inured to the blast from infancy, and as they spread their roots in all directions and penetrate chinks and fissures of rocks in search of food, and send down their tap root into the subsoil, they thus become securely fixed and moored as it were to the spot, so that it is seldom that we see such trees torn up by the roots during a gale. Fine examples of this may be seen in solitary trees in natural forests, and although such trees are exposed to the blast from all quarters, yet they are seldom torn up by the roots, although the tops and branches are often rent asunder and suffer severely.

NOTCH-PLANTING.—Many fine plantations have been formed in the north of Scotland and elsewhere by the cross-notch system of planting, and when the work is properly performed, and the roots spread out in a regular manner from the base of the stem, they are at once placed in a proper position to collect food and support the trees against wind attack from all quarters, and when young plants have been used, and the work carefully done, it is found that such trees establish themselves in a way little, if anything, inferior to such as have been raised on the ground by sowing the seeds. On the other hand, however, there is a system of notch-planting called the L notch, formed by two cuts with a spade at right angles, thus—L, and by pressing down the handle of the spade, the turf is opened up and the plant inserted at the corner. The spade is then withdrawn, and the turf trampled down with the foot, and the work finished. Now by inserting the plants in this way it must be evident that the roots cannot be spread out in a regular manner from the collar of the plant in all directions; consequently trees planted in this way are not only apt to be blown over, but from the roots being principally placed at one side of the tree only, they have to collect food from one spot, all of which put together forms a serious drawback to the stability of the trees and healthy development of the plant. Trees handled in this way are not planted, they are merely laid in by the heels; and although they may grow and appear all right for a time, yet by the time they require to be thinned to allow them space for development and the formation of timber, the evils of the system then become apparent by many of their number being upset by the wind during the first trying gale, and others so much loosened in the ground as to be a serious drawback to their healthy development in after years. The principal aim of the planter should therefore be to have the work thoroughly executed by insisting that the roots are spread out in a regular manner from the base of the stem, so that they can collect food from all quarters, and fix the tree securely in the ground at the same time, and thus lessen the risk of being uprooted by the wind during a storm.

COST OF NOTCHING.—The expense incurred for planting an acre by the cross-notch system is about 9s.; a man with a boy for inserting the plants can plant about 1200 plants per day in fairly workable ground, the distance apart being about $3\frac{1}{2}$ feet, which would give 3600 plants per acre, or a fraction more than what is required to plant an acre at that distance apart, the exact number being 3556. It will be seen from the above statement that the rate of wages allowed for the man and his assistant is 3s. per day. Now, it is not to be inferred that trees planted according to the above directions will always be proof against the blast; we only wish to impress upon the mind of the planter the necessity of using every reasonable means within his reach to give the trees fair play, and prevent as far as possible their destruction during a gale of wind.

PIT PLANTING.—This mode of planting is generally practised in the formation of hard-wood plantations, as well as in cases where it is necessary to use plants of a large size on account of the surface being overgrown by rank grassy vegetation. There can be no doubt in cases where it is really necessary to use large plants for the above or other cause, that the pit system is the best on account of the ground being well broken up, and the facility afforded for spreading out the roots of the plants, both of which are of vast importance for the success of the trees. In opening pits, the size of the latter should always be regulated to suit the size of the trees to be planted, and the subsoil should be thoroughly broken up and pulverised with a pick, and if possible left exposed to the weather for a few months previous to being planted. In performing the operation of planting the trees, these should be placed in the centre of the pit and the roots spread out to their full length in all directions from the base of the tree towards the sides of the pit, and by covering them with a portion of dry friable soil they will thus get a favourable start when they commence to grow in spring. Some planters, however, in place of planting the tree in the centre of the pit, place it in the corner of the latter, by which means they say that, by doing so, the young tree has two firm

sides to rest upon, and consequently is not so easily blown over as when planted in loose soil in the centre, and in this they are certainly right, but ultimately the evils of such a system show themselves, as the trees so treated never can establish themselves so firmly in the ground as those that have been planted in the centre of the pit, and the roots properly spread out in all directions from the collar of the plant. No doubt trees planted in loose soil will require to be examined in spring, and any plants upset by wind during winter will require to be set up and made firm with the foot, but as soon as they take to the soil and commence to grow they will give no further trouble; and as the roots will be enabled to gather food from all quarters, and act as cables to support and keep the trees in their proper position against wind attacks, no matter from what point of the compass the storm may come, the advantages of such a system must be immense. Now, on the other hand, by placing the tree in the corner of the pit, the roots are necessarily all on one side of the tree only; in fact, trees thus treated are not planted at all; they are in the same position as a fruit tree planted against a wall, they are merely wedged in between a hard bank of earth on one side and the loose soil in front, with the roots all one way, and although it may answer the purpose of keeping the plants firmly in their position at the outset, yet the system is bad, and should never be countenanced. Young trees naturally send down their tap roots to fix and steady the trees in their position, and extend their side ones in all directions, and any departure from this fundamental law of Nature, from whatever cause, is at the expense of the healthy development of the trees. The size of pits for ordinary young plants is about 18 inches wide and about 15 inches deep, and generally cost from 1s. to 1s. 6d. per 100 pits, according to the quality of the soil and rate of wages in the district where the work is to be carried out.

In the formation of plantations for utility, it is a matter of great importance for the success of the trees that each species be planted on soil the most suitable for its growth and healthy development. In the formation of ornamental plantations, one can improve the texture of the soil where necessary by adding fresh soil according to its requirements; but in planting trees for profit or utility, the case is quite different, as such a system would never pay; all we can afford to do in this case is to fence and drain the ground where necessary; then by selecting the trees most suitable for the different classes of soil, and planting them either mixed or in masses according to the circumstances of the case, we have every reason to expect our efforts to be crowned with success. Another point of importance, and one which should never be lost sight of altogether in planting for utility, is to plant as many as possible of the kinds of trees which will be wanted in the locality, and thus have a prospect of a ready sale. Thus in planting rich, deep, swampy ground, the different sorts of Tree Willows may be employed with advantage, as well as Alder, Ash, Poplar, &c., with a mixture of Spruce, Silver, and Scotch Firs for evergreen cover; and on clay lean resting upon clay, the Oak will answer as the principal with a mixture of Larch for nurses; the former feeds chiefly on the subsoil and the latter near the surface. Birch and Pine, again, are suitable for poor soil at high elevations, and mossy ground, and so on. All these points should be well considered and digested at the time of the formation of the plantations. J. B. W.

SHORT NOTES—WOODS AND FORESTS.

Charcoal. Can any reader of *Woods and Forests* tell me whether there is any market for charcoal in the south and west of England and at what price? There are large quantities of timber undesirable in this neighbourhood which would make capital charcoal, but it seems to have gone out of use for cooking now.—H. J. EWES, *Freston, Gloucesters.*

Autumnal tints. For truly gorgeous colouration in autumn some of the American Oaks bear off the palm. Perhaps the most beautiful is the Quercitron Oak, of the Eastern United States (*Quercus finctoria*), the fine deeply-lobed foliage of which, in autumn, exhibits a lovely combination of dark glossy green, crimson, and reddish brown, the green occupying generally the central portion of the leaf. *Quercus rubra* (the Red Oak) and its varieties are also noteworthy.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

FERNS.

W. H. GOWER.

THE LOMARIAS.

THESE are nearly allied to Blechnums; indeed the chief distinguishing characteristics are to be found in the fertile fronds. In Lomarias they are much contracted and wholly covered with sori, while in Blechnums the fronds are of equal width both in the sterile and fertile state. This distinction holds good for all ordinary purposes of identification; but, nevertheless, many genera merge so much into other genera, as to render it difficult to draw a line of demarcation. Lomaria contains some fifty species, some being very small and low in stature; others rise upon stout stems several feet in height, and bear large leathery massive fronds, which contrast well with Ferns of more delicate growth; moreover, as the majority of Lomarias are natives of cool countries they thrive in an ordinary greenhouse, and some are even well adapted for growth in Wardian cases. The sterile fronds of Lomarias are evergreen and very persistent; on the other hand, the fertile ones are somewhat fugitive, but while they remain they give quite a distinct aspect to the plant, and as they are for the most part produced annually, this fault may be readily overlooked. Large plants of Lomarias are very effective in the open-air fernery during summer, whilst smaller ones are equally useful indoors, and even as window plants. The following are among the best kinds. *L. discolor* is a bold, vigorous growing plant, which, when old, rises upon a short stout stem. It is a native of New Zealand, and thrives admirably in a greenhouse, or even in sheltered, shady spots in the open air during summer; the fronds are deeply pinnatifid, that is to say, they are once-divided, but the divisions do not extend quite down to the mid-rib. In cultivated plants we have seldom seen the sterile fronds more than 18 inches or 20 inches long, but in native specimens we have seen them upwards of 2 feet 6 inches in length, tapering towards both ends, and about 5 in. broad at the widest part. The fertile fronds are narrower, and usually wholly covered with sori; but in some cases the basal portion of the segments is leafy and auriculate. The fronds are of a bright lively green on the upper side and brownish white beneath, the sori, which are abundant, being chestnut-brown. *L. fluviatilis* is also a New Zealand plant, but wholly different in aspect from that previously named. The outline in this case is vase-like, the fronds being from 12 inches to 18 inches long and pinnate, with closely-set, almost round, segments of a pale green colour; the fertile fronds, which are about the same length, are erect, and bear narrow oblong segments, wholly covered on the undersides with deep brown sori, and thus furnished they form beautiful ornaments in a greenhouse or fernery. In *L. ciliata* we have a miniature Tree Fern, rising, when old, upon a slender stem. It comes from New Caledonia, and thrives best in this country in a cool stove or intermediate house. The sterile fronds are divided into segments, which are cut down nearly to the mid-rib. They are much lobed, very blunt (almost square), pointed at the apex, and fringed on the edges with teeth-like hairs; they are thin in texture and bright green. The fertile

fronds grow erect. *L. alpina* is found plentifully in the Falkland Islands, Cape Horn, and in various parts of Antarctic America. It is a very desirable plant for the outdoor rock garden, in which it forms a dense carpet consisting of deep green fronds, which seldom reach more than 6 inches in height. It may be briefly and familiarly described as a miniature form of our native species (*L. Spicant*), with shorter and more rounded segments. *L. blechnoides*, which comes from Chili, is well adapted for Wardian cases. Its fronds, which are from 5 inches to 6 inches long, have broad rounded segments, leathery in texture and deep green. The fertile fronds are usually wholly contracted, and bear narrow linear segments; more rarely, however, only the upper portion becomes contracted and fertile, these three characteristics being sometimes found upon one plant. In *L. capensis* we have a bold-growing plant, of massive appearance, from the cooler parts of South Africa. This species, when planted in a cool-house fernery, forms in a few years a majestic ornament, and in that state becomes a fine background against which to group smaller-growing and more delicately-divided Ferns. The root-stock is creeping, and the fronds vary from 1 foot to 3 feet or more in height. The segments, which are divided to the mid-rib, are from 3 inches to 6 inches long, rounded at the base, and tapering to a point. They are finely toothed on the edges, dark green above, but below slightly paler. *L. gibba*, though common, is none the less beautiful. It comes from New Caledonia and the various islands in the Pacific. It may be grown in a stove or greenhouse, or, indeed, in a dwelling-house. When old it forms a short trunk, which adds to its attractions, or it may be planted in the top of a dead Tree-Fern stem.

A variety of this species of Fern, called *Belli*, from Chatham Island, differs from the type in having all the bright green segments densely tasselled, but it has hitherto not proved to be a free grower. *L. Germaini*, which upon its first introduction from Chili went by the name of *crenulata*, makes a pretty ornament for a Wardian case. It produces quantities of underground suckers, which sometimes come up where not wanted, to the detriment of more delicate kinds. The fronds are simply pinnate, somewhat spreading, and finely notched on the edges; they are usually from 3 inches to 6 inches high and apple-green, the contracted fertile ones being erect. *L. lanceolata*, which is also dwarf and a fit companion for the preceding, has fronds about 9 inches high, the segments of which are, more or less, rounded at the points, and diminish downwards to the base. The fertile fronds are scarcely so high, and the segments are very narrow. *L. nuda* produces broadly-lanceolate fronds, divided almost to the mid-rib; they are from 12 inches to 18 inches long, and 5 inches wide at the broadest part. They are deep green, and arranged in a vase-like manner. The fertile fronds are smaller than the others, somewhat heavy in appearance, and do not add so much to the beauty of the plant as do those of most of the other species. This plant resembles *L. gibba* somewhat, but the points of the fronds are tapering, not gibbous, as in that species. A variety of *L. nuda*, called *pulcherrima* (which, by the way, we have seen with fertile fronds), is equally strong in growth. The upper halves of all its segments are deeply lobed, a circumstance which gives it the appearance of being crested. *L. nigra* is a curious little plant, a native of dense forests in the vicinity of Tauranga, in New Zealand, and a plant peculiarly adapted for Wardian cases; indeed, we have only seen it in good condition in such situations. It seldom exceeds 6 inches in height, and is often less; the sterile fronds some-

what resemble those of *L. blechnoides*, but they are intensely black-green, whilst the contracted fertile fronds resemble those of *L. fluviatilis* in miniature, thus suggesting the idea that it may be a natural hybrid. In striking contrast to the last-named kind comes *L. gigantea*, set upon a stout stem, furnished about the crown with an abundance of black, chaffy scales. It produces a dense head of pinnate fronds, which vary in length from 1 foot to 3 feet (according to the age of the plant), and are closely beset with deep green segments to the very base; the lower ones are, however, much reduced in size; the sterile fronds in this case help to enhance the beauty of the plant, as the segments, although narrow, are much longer than those on the sterile fronds. It comes from South Africa, and appears to be best at home in a stove. *L. Gilliesi*, which is a native of Chili, is an attractive plant, and one which thrives well in a cool house; its fronds, which are pinnate, are from 1 foot to 2 feet long; the segments are linear-lanceolate and pale green; the fertile segments are very narrow when wholly fertile, but in some instances the lower half only is contracted, the upper portion being leafy, thus affording an agreeable contrast. *L. L'Herminieri*, an elegant plant from the warm parts of South America, does not thrive in a cool house; it is a small species, producing once-divided fronds from 6 inches to 9 inches long and less than 2 inches wide, suddenly tapering to both ends; when young they are bright crimson, but afterwards change to pink, and finally become deep green. The fertile fronds are smaller and not very conspicuous. *L. magellanica* when old has a stout stem some 4 feet or more in height, the crown and base of which are clothed with long, harsh, brown, hair-like scales; the fronds, which are pinnate, are about 2 feet in length, ovate-lanceolate in outline, and the segments tough and leathery. They are deep green on the upper side, paler beneath, and bold and massive in appearance. It is an effective plant in an open-air fernery in summer.

There are in South America numerous forms of this plant, many of which have obtained distinctive names, and deservedly so, as when seen in a living state they differ materially one from another. *L. vulcanica* attains a height of from 9 inches to 12 inches; its root-stock is densely clothed with long, stiff, shining black hair-like scales; the fronds are pinnate, and this species is readily distinguished by the two lower segments being deflexed, thick, and leathery, and deep green. It comes from New Zealand, and is well adapted for culture in a Wardian case. *L. falcata*, from Tasmania, is an elegant cool house plant, the fronds of which are about 2 feet long and some 5 inches across at the widest part; the segments of the sterile fronds are bright pale green; those of the fertile ones numerous, narrow, and graceful. *L. procerca*, which is somewhat rare in cultivation, is both a handsome and distinct Fern. Its fronds are large, and the segments stout and leathery with thickened margins; they are deep green above, but paler beneath. In young plants the lower two or three pairs of segments are often much reduced in size, and the segments of the fertile fronds are shorter than those of the others and very narrow. It comes from New Zealand, and succeeds in a cool house. *L. Patersoni* is thoroughly distinct from any other species. It is a native of Australia. Its fronds are sword-shaped, from 9 inches to 18 inches high and about half an inch broad, tapering towards the base and pointed at the apex. They are deep green and the edges crenulate; the fertile fronds are about the same length as the others, but very narrow; at rare intervals the fronds assume a pinnate character, and bear one or two pairs of

narrow segments about the middle. In a Wardian case it is a very ornamental Fern. The last species which we shall enumerate is a bold handsome kind from Chili, and at home in the barly fernery, where it produces a distinct and bold appearance. It is *L. chilensis*, said by some to be the same as *L. capensis*; under cultivation, however, the two are abundantly distinct. *Chilensis* has a stout creeping rootstock, clothed with large brown chaffy scales, and the large arching fronds attain a height of from 4 feet to 6 feet, and have leathery, deep green segments. It is a plant that deserves attention on account of its distinctive character.

There is but little to say regarding the culture of *Lomarias*; all they want is plenty of root room, and if this cannot be had, they should be fed with liquid manure, mixed with soot, which increases the depth of colour in the fronds. For the strongest and most robust-growing kinds we prefer a compost consisting of two parts loam, one part peat, and one of sand. The smaller kinds should have less loam than those that are more vigorous. If young plants of *Lomarias* have not yet received their spring shift, it should be given at once, or the fronds will be liable to get crippled.

Brazilian Ferns (*B. W., Barnet*).—Your specimens are, 1, *Coptophyllum millefolium*, and 2, *C. buniifolium*. As far as we know, these Ferns have not yet been in cultivation in this country; indeed, they would appear to be rare even in their native habitats. They are species of great beauty, and we trust you may be successful in raising young plants from the spores. *Coptophyllum* is related to the *Anemia* family, from which it is distinguished by its fertile frond rising separately from the root and not from the base of the infertile one, as is the case in *Anemia* and *Anemidictyon*; such distinction is, however, not always considered of sufficient importance to establish a generic difference, inasmuch as the same thing occurs in *Osmunda*, *O. cinnamomea* being characterised by its fertile frond being wholly sporangiferous, and rising separately from the root. These two species of *Coptophyllum* were originally discovered by Gardner on dry hills in the north of the province of Goyaz, in Brazil. The fronds are much divided, and the segments almost as fine as hairs; indeed, without the fertile fronds they could hardly have been recognised as Ferns.—G.

PROPAGATING.

The propagation of all kinds of soft-wooded plants may now be proceeded with, that is to say, where the stock plants, after being partially rested during the winter, were a few weeks ago removed into a more genial temperature, and syringed occasionally, as they will now be bristling with young shoots, which, if taken off at once, strike very readily. These remarks apply more particularly to such things as *Fuchsias*, *Bouvardias*, *Heliotropes*, *Petunias*, and similar subjects, but the same treatment may be followed in the case of many other plants; for instance, the variegated variety of *Coprosma Baueriana*, which has been by many considered a difficult subject to strike, may be increased readily enough if the plants from which the cuttings are to be taken be placed in an increased temperature for a few weeks, and the cuttings formed of the young shoots made during that time. One thing to especially guard against is on no account to allow them to flag before insertion, as they seldom recover if much affected in this way. A few general remarks dealing with all the various subjects enumerated above may with advantage be herein given. In the first place, it is by no means necessary to leave a joint at the base of the cutting, though at one time this was considered absolutely indispensable, and where rapid propagation of any one particular sort is needed, this will be found a great advantage, for by cutting immediately above a joint, the naked piece of stem at the base of the shoot which is removed may be

inserted in the ground, and will root just as well as if one, two, or more eyes were buried in the soil. By this method the bottom joint with its attendant buds is allowed to remain on the plant, and thus forms a base from whence other and an increased number of shoots can spring, thus furnishing a second crop. When the cuttings are ready they must be dibbled into pots of light, open compost, pressed down very slightly, for firm soil so necessary in the case of hardwooded cuttings will retard the striking of such tender subjects. As these cuttings must be kept rather close till rooted, which will only take about a week or ten days, they must not be too much crowded (even though propagating room is scarce), and besides they are better if a thorough good watering is given before putting them in a close case, as then the superabundant moisture can drain away, and is not likely to cause damp. One other precaution to be particularly observed is that insect pests, especially aphides, are so prevalent just at this season, and they increase at such a rate in the confined atmosphere of the propagating house, that care must be taken if any are on the cuttings to clean them off before insertion. To prevent as far as possible the weakening effects of allowing them to remain a long time in a close atmosphere, the lights may be taken off every day for an hour or so, and as soon as the cuttings are rooted air must be given by degrees. Where possible the cuttings should be potted as soon as rooted sufficiently and hardened off, as then they grow away without check. A great many plants may be readily increased by means of cuttings of the roots, but of those herein mentioned the *Bouvardias* are the only ones that are treated in this way, and they are now more generally propagated by means of the young growing shoots than from the roots. To succeed with root cuttings, they should be taken from old-established plants and be of good stoutness, as the minor rootlets are very apt to decay instead of pushing up shoots. The roots should be cut up into lengths of about an inch and dibbled perpendicularly in the soil, after the manner of cuttings of the shoots, but as there is no foliage they may be put in much thicker than the shoots are. They should be put in at such a depth that the upper part of the cutting is just below the surface of the soil, and a little clean sand being sprinkled over the top the operation is complete. They may then be kept moderately moist, when, if plunged in a gentle heat and treated altogether as seeds, the pieces of roots will in time push out fibres from their lower portion, and a bud or buds will form on the upper end, and in time produce leaves.

DAHLIAS that have been wintered in the shape of dormant roots may be increased to an almost unlimited extent by planting-out time if the tubers are taken from their winter quarters, carefully examined to see that there are no signs of decay about them, and potted in some good, open, but not too rich soil. The tubers should be potted at such a depth that the crown of the plant is just covered with soil; or the roots may be laid side by side on a hotbed, and just covered with any light soil instead of potting them at all. This method is very good provided there are several tubers of one kind, but where single plants only are available for propagating purposes, they are better in pots, as there will then be no fear of any mistakes in the names, but if laid rather closely together on a bed or bench, errors in this respect may creep in, and are not easily rectified afterwards. Whichever way they are treated, a gentle heat of 55° to 70° must be maintained, when they quickly push up shoots, which as soon as long enough, can be taken off and put in as cuttings. They root with greater certainty if the shoots are taken off at the base, but in some kinds that do not push up so freely as others (and often the choicest varieties are amongst them) it is not advisable to treat all the shoots in this way, but a few of the principal ones should have an eye or two on the lower portion allowed to remain undisturbed, thus forming a nucleus from which other shoots will push. Where a large quantity is not desired, but simply to increase one's stock by two

or threefold, given tubers that were planted out last year to begin with, a simpler method can be followed with, in most cases, satisfactory results. It is to start them into growth a little before planting-out time, and when the shoots are about an inch in length, if the plants are examined, it will be found that most of them have pushed up more than one shoot. Then, if gone over carefully with a sharp knife, the clump of tubers can frequently be divided into as many parts as there are shoots, and if potted for a few weeks, they are then available for planting out. To dwarf the very tall *Dahlia arborea* it has been recommended to graft it on a tuber of one of the *Liliputian* varieties, but this is of little avail, as the point of union is below the surface, and consequently the scion forms roots of its own, and is thus placed beyond the dwarfing influence of the stock. To be effective the tuber of the dwarf variety must be started into growth, and when the stem is a few inches high it can be cleft-grafted with a shoot of *Dahlia arborea*, and if kept close for a week or ten days a union is effected.

SINGLE DAHLIAS can, of course, be increased by cuttings in the same way as the others, and this is the principal method employed for the propagation of the named varieties, but as seeds are ripened in such quantity, great numbers of seedlings are raised. Next month will be early enough to sow the seeds, as on a gentle hotbed the plants make their appearance in a few days and grow quickly during their earlier stages. With regard to cuttings of all the varieties of *Dahlia*s, they do best if inserted singly in small pots, a suitable soil for the purpose being equal parts of loam, well-decayed leaf-mould, and silver sand, the whole sifted fine. They must be kept close till rooted, and from their tender nature they are very susceptible of draughts or too much sunshine, but at the same time too humid an atmosphere must not be maintained, nor too much water given, as they are of rather a succulent character and apt to rot off suddenly. To prevent this as far as possible, a little air should be given every morning.

CLEMATISES.—The usual method of increasing the many beautiful garden varieties of this now popular flower is by grafting the young growing shoots on pieces of the roots of our common *Traveller's Joy*, and where this practice is followed out the stock plants are kept in pots, as they can be removed into a greenhouse temperature about this time and then start quickly into growth. The operation of grafting may be dealt with later on, but, at the same time, it is by no means absolutely necessary to graft them at all, as the young growing shoots will strike root fairly well, and plants obtained in this way never give any trouble by pushing up suckers. I have a quantity struck last summer, including the new *Jackmanni alba*, all of which are now ready to start strongly into growth. In any case, whether grafts or cuttings be the method employed, it is better to commence as early in the season as possible, for then the young plants will be well established before winter. T.

Vine insects (*J. L.*)—Your *Vine* roots are apparently injured by a small mite, very similar to, if not identical with, the *Eucharis* bulb mite (*Rhizoglyphus echinopus*). I could only find one or two colonies on the root you forwarded, but the whole root appears to me as if it had been attacked by them. I am sorry I cannot suggest any practical remedy except that of taking up the *Vines*, cutting off the injured roots, thoroughly cleansing the others, and replanting in fresh soil, or, perhaps better, planting fresh *Vines*. No insecticide will reach the mites with sufficient strength to kill them when the roots are in the ground. I have found that hot water of 110° or 115° Fahr. kills the mites; if the roots would stand immersion in water of that temperature for fifteen minutes, the mites would be killed, but I am uncertain if the vitality of their eggs would be destroyed. The mites much resemble grains of sand, but are rounder and more shining; they should be looked for with a magnifying glass.—G. S. S.

STOVE AND GREENHOUSE.

T. BAINES.

FORCED LILY OF THE VALLEY.

AMONGST hardy subjects forced in winter none are held in greater estimation than this charming little native plant, but when induced to come into bloom towards the end of the old year or the beginning of the new one success is not always achieved, for though most growers experienced in flower forcing are able to get Valley Lilies to bloom, still oftener than not the flowers forced so early are drawn and weak, and so far wanting in size and substance, that they are much inferior to those that come later on when less forcing is needed. One of the defects which the earliest-forced Lily of the Valley often presents is the absence of leaves in sufficient numbers to

requisite relief to the flowers. The way in which Mr. Elphinstone treats his Valley Lilies is to plunge the pots up to their rims in a brisk temperature, the thermometer sometimes showing as much as from 100° to 110°. Each plant is covered with an inverted pot, which is kept over it until some 2 inches of growth have been made, and after that the inverted pots are dispensed with. The crowns are deluged with water every day, given at a temperature equal to that of the bed in which the pots are placed, so that the soil is kept constantly saturated from the time the plants are put in until the flowers open. This thoroughly wet condition of the roots is considered to be essential to success, and I think there is little doubt that it is this saturation of the soil that enables the early forced crowns to produce leaves simultaneously with the flowers. Under this treatment the average time taken to force Lilies of the Valley is as follows:

Lily of the Valley forced, showing leaves as well as flowers. Engraved for THE GARDEN from a photograph.

set off the flowers to advantage. When required in a cut state only this deficiency is often met by forcing some of the thin crowns that have no flowers in them, and which at once push up leaves when placed in heat. But when plants of this Lily are wanted for ordinary purposes the want of leaves obviously cannot be met in this way. The accompanying illustration, prepared from a photograph, represents a Valley Lily sent to THE GARDEN office by Mr. Elphinstone, Shipley Hall, Derby, early in January, and which occupied only twenty-one days from the time when the crowns were put in heat to their arriving at the condition here shown. As will be seen, many of the spikes had nearly all their bells open; the individual flowers, too, were of unusual size and substance. In short, the plant taken altogether presented no more of the weak, drawn appearance that usually follows hard forcing than if it had been flowered in the open air, whilst the leaves were sufficient to give the

December 25 days, January 21 days, February 20 days, and March 15 days.

The best Abutilons.—The list of the best Abutilons given in THE GARDEN (p. 143) is certainly capable of being improved upon, for whereas some of Mr. George's varieties are undoubtedly among the very best, not one is named in the above mentioned list, and the rich crimson-coloured kinds, some of which are suffused with a violet sheen, are altogether omitted. Again, no mention of the best Abutilons would be complete without that vigorous-growing species *A. venosum*, which is such a good pillar plant for large conservatories, and for smaller structures the pretty little *A. vexillarium* is well worthy of a place. Of those mentioned by your correspondent, *Boule de Neige* is undoubtedly the best white we have, better indeed than *Seraph*, which may, however, be grown for the sake of variety. The yellows given are also good, but the brick-red coloured *Darwini robustum* and *La Lorraine* cannot be

classed under the head of rose-coloured varieties. Of rose flowers, including those with a lilac tinge, two good distinct kinds are *Anna Crozy* and *King of Roses*, while of reds, *Lustrous*, rich, glowing crimson, with very stout flowers, *Emperor*, rather a purplish crimson, and *Brilliant* are among the best. Of purples I should be inclined to consider as the best *The Premier* and *purpureum*, this latter being the deeper coloured of the two. In *striatum splendidum*, a hybrid variety, dwarfier than *striatum* itself, the flowers are of an orange colour, thickly veined with red, which makes it very distinct from any of the others previously mentioned. The large palmate foliage of *venosum* is very showy, added to which the bell-shaped, yellow flowers, conspicuously marked with crimson veins, are not only very attractive, but borne in great profusion, when the plant is allowed plenty of room to develop itself. *A. vexillarium* is a slender growing plant of a rambling character, with flowers of a very distinct shape from the others, the calyx being yellow, and the corolla which partly protrudes therefrom is deep purple. There is a variety of this in which the leaves are marbled with yellow. Considering the great beauty and distinct character of *A. insigne* it is a matter for surprise that it has not ere this become more common.—H. P.

WINTER-FLOWERING CARNATIONS.

BEING a great lover of Carnations, I have grown some of the winter-flowering section with what we call in the country a fair amount of success. For four years past we have grown *Miss Joliffe* exclusively, a variety always welcome. Last season I invested in one dozen (to me) new varieties. These arrived in excellent condition, so far as good plants were concerned. Each plant had a good stock of cuttings breaking out from the flowering stems. The dozen consisted of the following, viz., *Madame Carle*, *Alegatière*, *Mrs. Keen*, *Alexandra Regina*, *Bright Phoebus*, *Empress of Germany*, *Lucifer*, *Seraph*, *Sir George*, *Valencia*, *Vulcan*, and *Matchless*. Being desirous of having a thoroughly good stock of these charming flowers for the Christmas festivities, I grew about 300 plants, not forgetting my old love for *Miss Joliffe*, which I knew could be depended upon; 150 plants of that variety were grown. The cuttings were put in in the latter part of March. After being established in 3-inch pots, they were shifted into 6-inch pots, grown under glass in cool houses, and the promise which they gave me of a rich harvest was indeed a bright one. They were duly pinched back through May and June, and grew into remarkably fine specimens. In August we placed them outside, close to a south wall, well protecting them, and letting them stand there until the end of September. They were then removed to their winter quarters, which was a very light house, the plants standing well up to the glass in a temperature of 50°. After being at all this trouble, learning much, but netting little, the following is a truthful account of their behaviour. When we brought them into this house *Miss Joliffe* and *Madame Carle* were already bristling with flower-buds, and the same may be said, although in a less degree, of *Alegatière* and *Mrs. Keen*. These four varieties have been blooming all through the winter in profusion. *Empress of Germany*, a white one of which we have a dozen fine plants, has rewarded us with four single blooms. I therefore look upon the varieties just mentioned as being worthy of the name of winter-flowering Carnations, while the others have no just right to such a name. This opinion is based on practical experience, which I hope will keep others out of the pit into which I have unfortunately fallen.

Broughby.

RICHARD GILBERT.

Staphylea colchica.—When forced into bloom early in the season, this is far more effective than when allowed to flower naturally out of doors, for under glass the clusters of flowers are pure white in colour, whereas in the open ground they are tinged with green, and consequently do not so readily attract attention. Indoors, too, the delicate green of the partially expanded foliage is a

pleasing feature, and serves to set off the blossoms to advantage. This shrub has only within the last few years been valued for forcing, yet its beauty is such, and it is so distinct from others employed in this way, that it should be made a note of where plants of this kind are in demand. — H. P.

RHODODENDRONS UNDER GLASS.

WHEN simply grown in a greenhouse temperature—that is to say, without any of the forcing required to get many subjects in bloom at this season of the year—the early-flowering Rhododendrons are laden with bloom, and make just now a goodly display. One of the most attractive plants in the greenhouse at present is a bush of *Rhododendron præcox*, raised twenty-five years ago or thereabouts, between the pretty little hardy species *R. dahuricum* and the Sikkim *R. ciliatum*. It forms a compact-growing, much-branched bush, which is often used for the front rows of shrubby borders, for rockwork, and similar spots, for it will not grow too large, even if space is very limited. The flowers are of a very pale lilac colour, and borne in the greatest profusion. Though it does not flower for a month or six weeks later when in the open ground, yet even then it is frequently injured by spring frosts, while under glass the flowers retain their delicate tints to the last. From this kind, crossed with one of its parents, viz., *R. dahuricum*, was obtained R. Early Gem, another most useful variety, with the foliage of *R. dahuricum*, and flowers a good deal like those of *præcox*, but larger. Again, *R. dahuricum* itself is readily amenable to just the same treatment, and affords a pleasing change from the other two. It forms a rather upright-growing shrub a yard or so high, and bears great numbers of bright, rosy, purple-coloured blossoms about an inch in diameter. This species varies to a considerable extent in many particulars, some being, from an ornamental point of view, much superior to others. Another hybrid kind, Countess of Haddington, is under the same conditions, just unfolding its blossoms, and a goodly display they will make in another few days. This is the result of a cross between *Rhododendron ciliatum* and the straggling-growing Primrose-flowered *Rhododendron Dalhousie*, whose large bell-shaped flowers are so showy, but the plant is very rambling in habit and by no means robust in constitution. *Rhododendron Countess of Haddington* is a bold-growing kind, more vigorous, in fact, than either of its parents, but equally floriferous. As a proof of this I may mention that a small specimen here in an 8-inch pot has, from a clear stem a few inches high, divided off into nine branches, each of which is terminated by a fine plump flower-bud, two of them having already expanded blossoms. The earliest to bloom of all the Himalayan species, and one that will soon be in flower, is *Rhododendron argenteum*, which is of quite a tree-like habit, and furnished with stout leathery leaves a foot or so in length, and of a beautiful silvery whiteness on the under surface, from which character the name of *argenteum* is derived. The flowers are borne in large, closely-packed, terminal trusses, and in the bud state are pinkish, but after expansion they become white, with the exception of a dark blotch at the base of the throat. This species, too, in common with many others, passes through a very attractive stage just as the young leaves are in process of expansion, at which time they are altogether white, but more conspicuously so on the under than on the upper surface. Besides these above enumerated, the different hybrids of the tube-flowered section are in full bloom, and for months they have not been without flowers, but during the winter they succeed best in a temperature rather above that of an ordinary greenhouse. These have been so often noted in THE GARDEN, that no further mention of them now is needed, except to say that no garden where suitable structures exist for their cultivation should be without a selection of this beautiful class of plants. Besides the hardy Rhododendrons noted in the early part of this article as flowering well under glass, many of the various garden hybrids which impart such a charm to woodland scenery later on may be forced prematurely into bloom, and are then grand objects for the embellishment of the conservatory. The little hardy evergreen *Azalea amona* is now

under glass quite a mass of its bright purple blossoms, although no care whatever was bestowed upon it, except lifting it from the open ground, potting, and keeping it in a greenhouse temperature throughout the winter. Under the same conditions *Azalea mollis* is, though still leafless, bearing its large clusters of buff, orange, or salmon-coloured flowers. T.

CANTUA BUNIFOLIA.

THIS handsome plant (sometimes called *C. dependens*) is not so generally met with as it should be. The moderate growth and its inclination to climb rather than to form a bush fit it for use where dense bushy plants or vigorous growing climbers are inadmissible. Grown in a pot and trained to the rafter of a greenhouse or on a pillar, its beauty is best seen. It blooms in spring or in the early part of the summer, according to the warmth it is subjected to. It does not require much more warmth than will preserve it from frost. There is no difficulty in keeping it within bounds, the annual growth being moderate. It strikes from shoot cuttings, but the wood being wiry, we must secure cuttings when the young growth is in a soft state. The points of the shoots when about 4 inches long may be put in 6-inch pots, drained and filled with sand. Keep them fairly moist in moderate heat, cover with a propagating glass, and shade from the sun; they will soon strike. When rooted, tilt the glass a little, ultimately dispensing with it altogether. They should then be put singly into 3 inch or 4 inch pots. The plants will thrive in either peat or loam. Keep them in an intermediate temperature, with a moderately close moist atmosphere until they begin to move freely, after which let them have more air, and allow them to remain for a time where they will have more warmth than an ordinary greenhouse affords. This will enable them to attain a larger size than if kept cooler. During the summer give a little shade in sunny weather. They will require moving into larger pots before the plants become pot-bound. Give more air in autumn with less water at the roots, and winter them in a greenhouse temperature. I have said nothing about stopping the shoots, an operation that is seldom necessary further than pinching out the point of the leading one, and which, if the plants break of their own accord so as to make two or three branches, will not be necessary, as the object is to get them on in height rather than to assume bush form.

In spring, just as growth is about to commence, shift into pots two or three sizes larger, and encourage the plants to move freely by keeping up a genial humid atmosphere, with plenty of light, giving air in the middle of the day and a little shade in bright weather. The syringe should be used freely every afternoon when the house is closed. The plants may now be stood where they are to remain, training their shoots to the pillar or rafter they are intended to cover. From this time all that is necessary is to give more pot room as may be required. This plant will, however, do with smaller pots than many things after it has attained a size sufficient to show its character, provided that a little of the surface soil is renewed each spring, and manure water or other stimulants are given during the time the growth is being made. When planted out the bed or border should be much smaller than that required by stronger growing subjects.

In regard to pruning, proportionately less will be necessary than with vigorous growers, simply shortening back any shoots that seem to require it. This should be done after the plants have flowered. Treated in this way, this *Cantua* will last for many years. T. B.

Kæmpferia ornata.—This new and beautiful *Kæmpferia*, which was recently introduced to cultivation from Borneo by the *Compagnie Continentale d'Horticulture*, is as yet but little known in gardens. Its rather long-stalked, sharply-lanceolate leaves are dark green on the upper

surface, and present on the whole a slightly velvety appearance. On each side of the midrib, and contiguous to it, is a broad, irregular, silvery-white band. The under surface is purple. The flower-spikes, which rise from the sheaths of the leaves, bear rich orange-coloured flowers of moderate size. In a gardening point of view, the importance of this plant undoubtedly lies in its beautifully marked leaves and graceful habit, characteristics which will readily secure for it a prominent place in all ornamental collections. A plant of it is now in flower in the stove at Kew. —A. Z.

CHRYSANTHEMUMS FOR THE CONSERVATORY.

HAVING a large space to fill up, I find that large plants help to do so in such an effective manner, that I will briefly describe the way in which we obtain them. When the plants go out of flower I set aside a certain number of one-year-old plants to grow on into specimens for the next season's flowering.

These plants will not produce such large blooms as young ones, but they will give a far greater number, and as we only want them for effect, the more flowers we can get the better, as we depend on young plants to give the largest blooms. These old plants entail less labour than the others, and one specimen will fill up as much space as three plants raised from cuttings the same season. I consider the incurved and reflexed varieties are best suited for this purpose. The sorts I prefer are Mrs. G. Rundle, G. Glenny, *arcum multiflorum*, Pink Perfection, Mr. Bunn, Venus, Prince of Wales, Fingal, Cherub, and Hetty Barker. Some of the dwarf-growing Japanese varieties do fairly well, especially Golden Dragon, Gloire de France, and Cossack. The most suitable place for them up to the time they are repotted is a cold pit or frame where they can have pl-nty of air without being exposed to frost. About the middle of April they may have about two-thirds of the old soil shaken away from the roots, and then put into their flowering pots. The weakest growers should occupy pots 12 inches in diameter, and the strongest 2 inches larger. Good fibrous loam and a little sand are what we use as a compost, in which they make satisfactory growth. The plants may remain in the frame until the end of May. On all favourable occasions the lights should be drawn off after the beginning of May, the object being to get the growth firm. During the summer I have dealt with the plants in two ways, with very little difference in the results, except that by the one plan I did not get so good leafage near the bottom of the plants as by the other. The first plan was to plunge the plants in a bed of soil, quite covering the pots, so that the roots could get over the rims as well as through the bottoms. These plants were perhaps a trifle larger, but, owing to the mass of roots which had found their way outside the pots, they lost a good many of the bottom leaves after they were lifted in the autumn. Plants thus treated require less water than those which stand on the surface. The loss of some of the bottom leaves is not a serious disfigurement when the plants are wanted for massing. I gave the plants that were grown in this way very careful treatment. They were lifted carefully at the beginning of October, and not a root was injured at the time, except those that were damaged in coming out of the soil. All the roots as well as the soil that adhered to them were left intact, and the plants placed on the floor of a greenhouse, which was kept close for a week, and the plants syringed two or three times a day. By leaving the roots on the plants as they were lifted, the check was not so severe, as the dry air of the greenhouse soon caused these roots to shrivel up sufficiently to allow us to remove them altogether, and to cleanse the pots before they were wanted for the conservatory. The plants suffered less than they would have done had we removed the roots when they were taken out of the ground. Where the loss of the lower leaves is of no consequence, I can certainly recommend this plan in preference to leaving the pots exposed to the air, as the saving in labour is very great; but it must not be understood that they will do without the assistance of the watering-pot altogether. They will require liberal supplies

in dry weather, especially at first, but after that much less will serve them. The other plan is to set them on a hard surface, so that the roots cannot find their way out of the pot. When this is practised, most of the lower leaves may be kept green and fresh, which enhances their appearance when the plants have to occupy prominent positions. But whether they are grown on a hard surface, or plunged in a bed of soil, they yield such a quantity of flowers, that I would not willingly be without them. It is not unusual to see as many as 130 to 150 flowers on such varieties as Mrs. G. Rundle and aureum multiflorum, and this with only a minimum amount of training. On the large flowering varieties I leave about eight strong stems, and on the others twelve. Early in June the shoots are pinched, and then allowed to grow, and when necessary staked. The other details of management are the same as are given to the general stock J. C. C.

GESNERA CINNABARINA.

This useful Gesnera has been in flower here since November, and we find it very handy in many ways, particularly as a vase plant indoors, where the rich colours of both its foliage and flowers intermixed with Ferns have a striking effect. When done flowering, the stems are cut off, and the plants are placed near the light in a stove to ripen their tubers, just sufficient water being given them to keep the foliage from flagging. As soon as the tops have died down and have been cleared away, the pots are taken to a warm greenhouse and laid on their sides underneath the stage, or stored in any out-of-the-way corner where the temperature does not fall below 50°. About the end of May the tubers begin to grow. They are then taken out and assorted as to size, the largest being put singly in 6-inch pots, and of the next size we place three in a 6-inch or 7-inch pot. The compost which we use is turfy loam, leaf mould, and silver sand in equal proportions. Our tubers are now put into the pots in which they are intended to flower. There is no advantage obtained by putting the bulbs into small pots and then shifting them into larger ones. They require plenty of drainage; we therefore fill the pot half full of potsherds; on this a thick layer of the mould is put, and on it the tubers are placed, and covered about an inch deep; the soil is pressed gently around them, but in no case should it be pressed hard. As soon as potted they are placed in a vinery, in which the temperature ranges from 60° to 65° at night. No water is given till the young leaves appear, and then it must be carefully administered until the roots have taken good hold of the soil; after this they should never be allowed to get dry. They remain in the vinery until they get 3 inches or 4 inches high, when they are removed to a warm pit and kept close to the glass. Here they are grown until they begin to show bloom, when they are taken to a stove in which to open it. On no account must they be syringed or water spilt over the leaves, as it is sure to disfigure them, and they must be kept shaded from the direct rays of the sun. Treated in the way just described, they make strong, robust plants, from 2 feet to 2½ feet high, with numerous side-shoots that flower as freely as the main stems.

W. WATSON.

Eglchturst.

Alpinia pumila.—This beautiful Scitameneous plant, a native of the Malay Archipelago, does not seem to be a favourite in gardens, owing doubtless to its size and lax habit after a few years' growth in a warm moist house. It was introduced to cultivation some sixty years ago, but was soon afterwards lost, and only reappeared some few years since. The stems of a plant now flowering in the Palm house at Kew have reached a height of about 9 feet. The leaves are about a foot long and from 4 inches to 5 inches broad, quite smooth, lanceolate, and tapering to a sharp point. They are bright green on the upper surface, paler green beneath, and have a still paler midrib. The flower-spike is covered with short silky hairs, and is clasped at the base by a striated sheath from 3 inches to 5 inches long. The flowers are about 3 inches in length; the petals are pure white, and the lip

broad, ovate, recurved, and bright orange in colour, marked with scarlet stripes.—A. Z.

SEASONABLE WORK IN PLANT HOUSES.

ARISTOLOCHIAS.—Those who are fond of singular-looking flowers can scarcely fail to appreciate the merits of these climbers, which, in addition to their distinct appearance, have the further good property of being free-growers and free-bloomers, producing their distinct-looking flowers in succession during summer and autumn. The plants are easily propagated from cuttings, which, if put in in a brisk heat now, will strike in a few weeks. They will last for years, but when grown in pots it is as well not to keep them until they are old, as young stock raised from cuttings at this time, and grown on freely during the summer, will make large specimens the ensuing year that will often flower quite as well as older examples; consequently, it is advisable to have young plants coming on to take the place of those that are discarded. Strong-growing sorts, such as *A. gigas* and *A. ornithocephala*, when their roots are confined within the limits of even a large pot, exhaust the soil to an extent that necessitates a greater proportion of it being shaken away at the time of repotting than is necessary with less vigorous growing things. Plants that were cut back a short time since should now be turned out of the pots, removing as much of the old soil as can be got away without breaking the roots and replacing it with loam made richer with rotten manure than plants that are less vigorous in growth would require; 18 inch pots will not be too large for full-sized specimens of the strong-growing kinds. When planted out it is not well to give them too much root room, otherwise they make so much top-growth as to encroach upon everything near them. The beds in which their roots are located should now have a dressing of rich soil applied, removing an inch or two of the old material to make way for it. *A. elegans* is a comparatively new species of unusual merit. The flowers are smaller than those of the largest species, but the beautiful combination of colours which they possess, and their singularity of form, place this species in the front rank of stove-climbers.

THUNBERGIAS.—The climbing kinds of Thunbergia are best suited to a large house where they have sufficient head room to admit of their tops extending in the way their vigorous habit of growth necessitates. They require to be pruned close in after flowering; presuming this has been done, the plants when grown in pots will be in a condition for repotting. Like the Aristolochias, as much of the old exhausted soil should be removed as can be got away readily, replacing it with new rich material. In addition, moreover, manure water will require to be used freely during the time in summer when the season's growth is in full force. Cuttings of these Thunbergias should now be put in, for though the plants will last for many years, it is well to always have a few young examples in reserve to take the place of any that it may become necessary to clear out. Cuttings treated in the ordinary way strike freely, and the plants in their after stages are amongst the freest and easiest to grow.

FINE-FOLIAGED PLANTS.—Taking into account the many ways in which the different kinds of fine-leaved stove plants can be used for very many purposes, they have become of nearly as much importance as the flowering section, especially when grown under conditions that give the requisite substance and endurance to their foliage that will enable the plants to be moved for a time in summer to quarters where they will be under the influence of a lower temperature than that of the house in which they have been grown. To admit of this they must, during the spring and early part of summer whilst in active growth, be subjected to all the light that can be given them, keeping them well up to the glass. The semi-darkness in which these fine-leaved stove plants are often kept is just the reverse of that which is calculated to secure the robust growth so much desired.

ANTHURIUMS.—Several of the fine-leaved Anthuriums, such as *A. Warocqueanum*, *A. crystallinum*, and *A. Veitchi*, are deserving of a place in the most select collection. They succeed best in light, open material, such as a mixture of fibrous peat, chopped Sphagnum, broken crocks, or charcoal and sand. Even when grown in such porous compost as this it is better to renew the soil at this time each spring before growth commences, as the roots will not thrive if it is too far decomposed, a condition to which the amount of water the plants require soon reduces it. The old material should be carefully shaken away from the roots: in repotting it is well to half-fill the pots with crocks, as these Anthuriums are surface-rooters. To grow them in a way that will admit of their leaves attaining their full size when the plants are large they must not be stinted for root-room; 16-inch or 18 inch pots are not too large for full-sized specimens, but, except where there is some special object in view for growing large plants, smaller examples are more useful.

ALOCASIAS.—Some of the best kinds of Alocasia increase by the production of tubers as well as by the multiplication of their crowns. Now, when the plants are repotted, these should be removed and grown on by themselves for a season. Soil of a like description to that advised for the Anthuriums will answer in every way for most of the Alocasias, and in potting it is well to give plenty of drainage, as the plants succeed best when their roots are near the surface.

MARANTAS.—These plants should now be repotted, and where the stock is to be increased the crowns ought to be divided more or less according to the size required. In effecting the division care must be taken not to mutilate the roots, as Marantas do not recover so readily as many things when they suffer in this way. When the plants are divided in this manner they should be kept somewhat close until the roots have begun to move freely, giving no more water than is necessary to keep the soil slightly moist.

DIEFFENBACHIAS. Now is the right time to repot these showy plants. They will thrive in either peat or loam, with enough sand to keep it open. Most of the old material should be got away. In potting, make the soil moderately firm. Where the stock has to be increased, this is easily effected, as the thick, fleshy stems, if cut into lengths of a few inches, root readily in sand, keeping them warm and shaded. Medium-sized examples, each consisting of two or three stems, will be found to be the most useful.

PANDANUS.—These plants are much more useful in the form of small examples, consisting of a single crown, than when larger. The suckers, which large specimens of most of the varieties produce freely, root readily in a brisk heat; they should be taken off with all the stem that can be got attached; a few of the lower leaves must be removed, placing them singly in small pots. Stand in a brisk heat, but do not confine them too much; they are light-loving plants; consequently when sufficiently established they must be kept well up to the glass, without which the leaves come weak and are wanting in endurance. In the case of the variegated kinds, *P. variegatus* and *P. Veitchi*, suckers should be chosen that have sufficient of the white colour in them; if this is not attended to the plants when established will most likely remain deficient in this respect. Where large specimens are required proportionate root room must be given, at the same time it is well to remember that all these Screw Pines will thrive in smaller pots than most things.

CROTONS.—Large specimens of these may be grown in smaller pots than are frequently given them, provided manure water is applied freely during the time the plants are making growth, yet from the fact of their being free rooters they must not be kept for an indefinite time without a partial renewal of the soil. Large examples that have been cut in since their growth was completed last autumn will have now pushed young shoots, and should be turned out of the pots and have some of the old material from the tops of the balls

removed, replacing it with new; good yellow loam, with some sand, suits them in every way, giving manure water freely in the active season. Contrary to what might be supposed, the leaves come finer coloured when so treated than when the plants are kept poor. Few things are better suited for the various purposes for which small plants are now used than the drooping narrow-leaved varieties of Croton, as, notwithstanding their requiring a comparatively high temperature, they will bear removal for a time during the summer season to cool houses and living rooms. Cuttings composed of the points of last summer's shoots, about 6 inches long, if put in now will root readily, and if grown on freely in a warm stove will attain a useful size before autumn.

TUBEROUS BEGONIAS.—These should now be started. If wintered in the old soil in which they

using a little more moisture in the atmosphere. Shading materials should be got ready, as it not unfrequently happens that the sun is so powerful early in the ensuing month, that if means are not taken to protect the young, tender leaves, they suffer proportionately more than they would later on, when, if the solar rays are more powerful, the plants are in a better condition to bear them. Whatever is used for shading, it should be moveable, without which the majority of the plants will be wanting in the substance of their leaves. T. B.

FLOWER GARDEN.

HERBACEOUS AND SHRUBBY CLEMATISES.

THE great improvements that have, within the last few years, taken place in our garden Clematises,

The general practice is to leave them unpruned until spring, when they are merely cleared of dead wood, leaving shoots on which there are fresh healthy buds undisturbed. They are sometimes also cut down altogether, and, I am told, with good results, but I have not had sufficient experience of this practice to recommend it. Kinds possessing a woody character will only require the removal of the superfluous shoots annually. They flower on the current year's wood, and all properly placed shoots should be left so as to ensure good young growth. Such sorts as *C. graveolens*, *C. montana*, *C. cirrhosa*, and others do well in ordinary garden soil of good depth, but we, nevertheless, find a top-dressing occasionally to be very beneficial to the majority of them. Clematises may be used in various ways, but that in which we think they look

C. graveolens.

C. aethusa-fofolia.

were grown last season, they must be shaken out and repotted in fresh soil, giving pots proportionate in size to that of the tubers. Although these Begonias during all the stages of their growth will succeed in a greenhouse temperature, still, if they can have a little extra warmth for a time until the roots and tops have made some progress, it will be better. This is especially the case with small tubers which, when so treated, attain extra strength early in the season, by which means they are able to flower better than when the growth is made slower.

TEMPERATURE.—The temperature of the stove should now be raised both day and night proportionate with the requirements of the plants grown,

tises, as well as the introduction of new kinds, have deservedly raised them to the foremost rank amongst hardy climbers. *C. Jackmanni* may be seen almost everywhere, and used in all sorts of ways. In the neighbourhood of London especially hardly a garden worthy of the name is without a plant of it. I have even seen it flourishing in window boxes, and it is not at all unusual to see verandahs entirely covered with plants of it growing in small boxes. In the case of this Clematis and its hybrids, good rich soil should be used unsparingly in the first instance, and a top-dressing of good manure should be added annually afterwards, or at least when required.

best is creeping over old stumps or draping trees, which they do very gracefully. Many of them are also very effective overhanging large boulders in the rockery, such as we see in Battersea Park and in the new rockery at Kew. Old ruins, walls, isolated heaps of brickwork, and old roots may all be improved and beautified by these charming climbers. Amongst the most useful are *C. Flammula*, a native of Southern Europe, but as hardy and free as the wild *C. Vitalba*. It looks well on old rockwork or tree stumps, producing dense panicles of small white Hawthorn-scented flowers. *C. carulea*, a near ally of *C. florida*, introduced from Japan about

1834, has large pale violet flowers. It is the parent of many garden forms, both single and double, none of which surpass the type in beauty. *C. graveolens*, here illustrated, is another species with strongly scented flowers, which are pale yellowish green; although not so ornamental as

hide the foliage. It is a native of Nepal, and blooms during the greater part of the summer. *C. viticella* is another well-known species, a native of Spain and Italy, and one which has sweetly scented flowers. Under cultivation it has become greatly improved; its flowers, which are large, are reddish purple, and there are double forms of it. It is not such a rampant grower as *C. montana*, but when allowed to grow unchecked on low trees or on rustic supports, it makes a very effective plant. Others are *virginiana*, *Vitalba*, *ligusticifolia*, *lanuginosa*, *floridissima*, *crispa*, *balearica*, &c. Clematises suitable for herbaceous borders or beds are also very numerous, and when run over rustic supports, such as the tops of small Larches, they look truly beautiful mixed with other plants.

are very ornamental. It is useful for copes, covering old stumps, and it is also effective in mixed borders. It is a native of Southern Europe, and flowers in summer. *C. Viorna*, the Leather Flower of the United States, is a pretty small-flowered species, the sepals of which are thick and leathery and purplish in colour. The variety *coccinea* is a native of Texas, and has only recently been brought into notice. It is one of the prettiest of the small-flowered section;

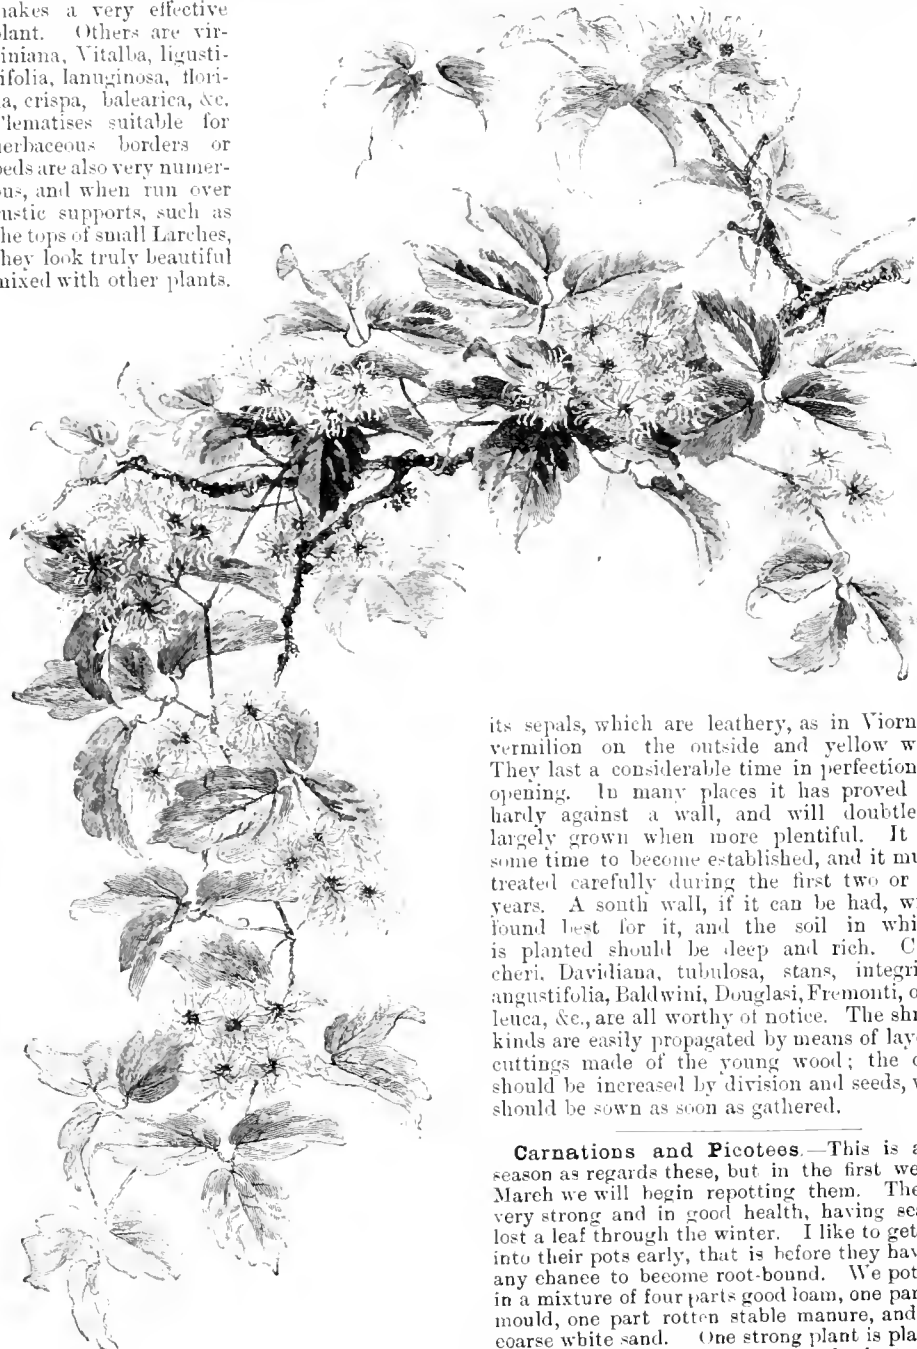

C. cirrhosa.

those of some kinds, they are produced more plentifully, and the fruits with their long feathery tails remain until November. *C. graveolens* is a free grower, and does well in any partly sheltered spot. The leaves, which are triterminate, have a pretty glaucous sheen, not unlike that of *C. songarica* or *angustifolia*. It was introduced about 1844 by Captain Munro when in India, but it is also found in Chinese Tartary. *C. cirrhosa*, the Evergreen Virgin's Bower, is an interesting early kind. Its flowers, which are white or greenish white, are produced in bunches, as may be seen by the annexed illustration. It

C. campaniflora.

is comparatively hardy, and flowers freely in sheltered positions. In floral brightness, however, few equal *C. montana* var. *grandiflora*, a perfectly hardy sort, even in the most exposed situations, and one which produces such a profusion of large pure white flowers as to entirely

Traveller's Joy (*C. Vitalba*).

Most of them flower all through the summer months, and many are useful in a cut state for wreaths, &c. Among these may be mentioned *C. aethusefolia*, a native of Northern Asia. Its flowers, as may be seen, are thimble-shaped, and produced in great profusion all through the summer months. Being nearly white they are shown off to advantage by the pale green foliage. *C. campaniflora* bears a profusion of pale purplish flowers, which

its sepals, which are leathery, as in *Viorna*, are vermilion on the outside and yellow within. They last a considerable time in perfection after opening. In many places it has proved quite hardy against a wall, and will doubtless be largely grown when more plentiful. It takes some time to become established, and it must be treated carefully during the first two or three years. A south wall, if it can be had, will be found best for it, and the soil in which it is planted should be deep and rich. *C. Pitcheri*, *Davidiana*, *tubulosa*, *stans*, *integrifolia*, *angustifolia*, *Baldwini*, *Douglasi*, *Fremonti*, *ochroleuca*, &c., are all worthy of notice. The shrubby kinds are easily propagated by means of layers or cuttings made of the young wood; the others should be increased by division and seeds, which should be sown as soon as gathered. D.

Carnations and Picotees.—This is a late season as regards these, but in the first week in March we will begin repotting them. They are very strong and in good health, having scarcely lost a leaf through the winter. I like to get them into their pots early, that is before they have had any chance to become root-bound. We pot them in a mixture of four parts good loam, one part leaf-mould, one part rotten stable manure, and some coarse white sand. One strong plant is placed in a 7-inch pot, two medium or weak plants in an 8-inch, and two stronger ones in a 9-inch pot. —J. D.

Polemonium Richardsoni.—Having just received Mr. Ware's catalogue, on the outside of which is figured a large head of *Polemonium*, called *P. Richardsoni*, I write to say that I think it a pity that plants should be distributed by wrong names, and that the plant figured certainly cannot be *P. Richardsoni*, which is correctly figured and described in the *Botanical Magazine* (tab. 2800). It is a dwarf trailing plant closely resembling *P.*

humile. Mr. Ware's plant is one of the fine North American varieties of *P. cœruleum*, of which there are now many in cultivation, varying considerably from seed. The plant Mr. Ware exhibits outside his catalogue received a certificate in 1885 from the Royal Horticultural Society under the name of *Richardsoni*, and both before and since has figured in gardens under that name which a reference to the Kew herbarium or the *Botanical Magazine* will prove to be wrong. The nearest approach to Mr. Ware's plant I can find in any figure given and described on good authority is in Edwards' *Botanical Register* for 1830 (tab. 1303). It is there called *P. cœruleum* var. *piliferum*, and is described by Lindley who says it was raised from seed sent from North America by Dr. Richardson, and flowered in the garden of the Royal Horticultural Society. The next plate (tab. 1304) is called *P. humile*, a dwarf plant distinct from the others, but considered, says Lindley, by Dr. Hooker to be identical with *P. Richardsoni*.—C. WOLLEY DOD, *Edg. Hall.*

SPRING-FLOWERING ANEMONES.

THESE are all great favourites with lovers of hardy flowers, and well they deserve to be, for few other groups of alpine are more accommodating, or yield a greater amount of pleasure amidst the trouble taken with them. The common *Hepatica*, so well known in every cottager's garden, has of late years been multiplied into almost endless numbers, each vying with the other in the richness or delicacy of its tints, or in the almost perfect doubleness of its flowers. All are worth growing, and I make a point of adding every new shade of colour I happen to meet with to my collection. They are now beginning to peep up everywhere, those in the most sheltered places being ready to burst forth with the first gleam of sunshine. They are easily managed, simply planting in good rich soil and leaving them alone. All of the varieties we yet possess belong to *Hepatica triloba*, but *Hepatica angulosa* is a much taller species, with larger, handsome starry blue flowers, and equally easy to manage. Our own wood *Anemone*, and especially the handsome variety called *Robinsoniana*, are hardly to be equalled among species of that class. The last does extremely well with us on the shady side of an old rockery, producing annually flowers in great abundance. They are larger than in the type, and suffused with a lovely blue colour. The type, however, itself is not to be despised, as when grown in the wild garden, where it reveals, it yields an amount of pleasure which few other plants under the same conditions afford. *A. trifolia* is nearly allied to the above, but readily distinguished by its very regularly toothed leaves, while those of our English wood *Anemone* are cut irregularly, and toothed somewhat like *Anemone ranunculoides*. *Anemone trifolia* replaces *Anemone nemorosa* from Remo to Genoa, in Italy. It has large flowers an inch or so in diameter, and makes a fine subject for sloping banks on or near the rockery. *Anemone ranunculoides* we have always found easy to grow. It is a charming free-flowering species, with prettily cut foliage; the flowers of the normal form are golden yellow, while those of the variety are pale sulphur, and not nearly so striking. *Anemone palmata*, which we always raise in abundance from seed sown in beds in the open air, is also a pretty plant for the rockery; we grow it on dry, exposed places, and never fail to get abundance of its large shiny yellow flowers. In the pure white variety, the leaves are few and small in proportion to the quantity of blooms it produces. It seems to do best in a light sandy soil. *Anemone vernalis* is a very dwarf species, the whole plant being not more than 1 inch or 2 inches high. The leaves all rise from the base, and are trifoliate, the leaflets again being divided almost to the midrib. The flowers are curious, solitary, reddish purple, the outer divisions densely covered with long silky hairs, and presenting a very singular appearance. The involucre is also noteworthy, from its rough, unceath appearance. *Anemone pratensis*, which seems to be more rare

in our gardens than any of the above, is the nearest approach to a black flower of all the *Anemones*. This has deep lurid purple flowers, with finely divided leaves, and is really a most desirable addition to our collections. *Anemone Pulsatilla* varies from red and lilac to white, and does well in exposed places planted in lime rubbish. There are many others, such as *Anemone apennina*, *blanda*, and *sylvestris*, which are equally beautiful and interesting. K.

THE PINK STIGMA OF HELLEBORUS ALTI-FOLIUS.

HERR MAX LEICHTLIN'S experience is so great that he cannot approach any botanical subject without throwing additional light upon it; he does not, however, quite take in my views, nor consequently does he, as I think, controvert them. My starting-point is that *altifolius* is either a distinct species, or, if not, it has wandered from its type beyond power to revert to it; there are others more or less connected with it. Herr Max Leichtlin, equally with me, recognised Mr. Engleheart's plant as *altifolius*. I recognised it by the presence of a robust form, cupped flower, and pink stigma; he did so, although in the plant in question its characteristics were at variance with what he postulates for the wild form, viz., slender habit, flat flower, and white stigma. I do not for a moment doubt that the latter is one form of *altifolius* any more than I should doubt the claim of a white Foxglove as well as the red to be typical, except in colour, but all the evidence I have leads me to believe that amongst wild *altifolius* the great majority of plants have the pink stigma, whereas amongst all the imported wild plants of niger typical which I have seen or heard of none are so marked. Where I have seen one Herr Max Leichtlin has probably seen a hundred, and his experience may be different, but I scarcely consider the cases he mentions can be taken in evidence. *Niger præcox* is not niger typical, and in the case of the typical niger it is not stated whether the parent plant might not have been exposed to foreign pollen. We rather want wild specimens of both niger typical and niger *altifolius*, the former gathered from hunting grounds where the latter is non-existent. Mr. Baker cites Reichenbach as the authority for *altifolius*, and I think I am not wrong in saying that his plant, the original of the name, has the red stigma; and it is not only in the colour of the stigma and in its size and shape, but also in the colour, form, and texture of the leaves, that *altifolius* and several others with red stigmas generally differ from the niger type. From the appearance of the Brockhurst *angustifolius*, I had expected the red stigma to be present, but until I received specimens from Mr. Veitch a few days ago I had never detected it. I cannot judge of Miss Hope's *angustifolius*, having only one plant with green stigma; but from its appearance I should expect the red stigma to develop itself in this variety also. It is a trite saying that exceptions prove the rule, but I should indeed be sorry could it be shown that in the wild habitats of niger typical even one per cent. is found to weaken the convenient rule for which I contend.

Hellebores have a grievance against science, but even were the species more accurately defined, amateurs are not generally up to nice distinctions in such a complicated family. They want easy general rules, and science must fill up the details. We have discussed one rule; let me give another. Many of the plants figuring under the *viridis* section, to the casual observer, are much alike, but call in the aid of smell, and the amateur will readily detect a difference; he will meet with a considerable Elder-scented group, of which *Bœconi* is a prominent example, and perhaps *odorus*, with its more refined perfume, an aristocratic member; thus tested, no one would confound one of these with the rank, poisonous-smelling *viridis* proper. *Dumetorum*, again, is comparatively scentless. Again, as between *antiquorum* and *olympicus* true and *olympicus* major, as I used to

call it forty or fifty years ago, I believe it is a safe rule to lay down that *olympicus* never shows pink on the sepals; *antiquorum* always does, more or less. Herr Max Leichtlin suggests that the difference in pollen grains prevents crossing between niger type and niger *altifolius*. Now, I succeed easily with most of the Hellebores, crossing indifferently persistents and non-persistents, and, as if to emphasise the difference between the Elder-scented group and *viridis* proper, I have never had a cross from the latter, but the Elder-scented (non-persistents) cross with persistents, and the results have been persistent foliaged plants with Elder scent. I have been unsuccessful also with *trifolius* (*argutifolius*) and with *foetidus*. Has Herr Max Leichtlin been more successful, or has he examined the pollen grains to account for failure? T. H. ARCHER-HIND.

South Devon.

NARCISSUS CYCLAMINEUS.

THIS newly-discovered *Narcissus* came into flower here about February 15, in the open border under a south wall, about a fortnight after it had begun to flower in the greenhouse. The bulbs were sent from Portugal by Mr. Tait, and were planted last July. I find the habit of bulbs imported from the south of Europe to flower the first season at the same date as they flower in their native country, but fortunately they soon learn better in the English climate. I am afraid *N. cyclamineus* seems likely to be delicate, and will have to be treated here as a frame bulb. I have already noticed two, of which the leaves withered before flowering and the bulb had rotted. As regards the natural history of this curious species, an opinion has been given that it belongs to the Ajax section of *Daffodils*. Ajax was a generic name adopted by Haworth for what Mr. Baker classed as *N. pseudo-narcissus*, and *N. cyclamineus* certainly is not a variety of that species. A more plausible opinion was given that it is a hybrid between *N. pseudo-narcissus* and *N. triandrus*, and it is true that it presents characters intermediate between the two, especially in the leaf. But nearly half the so-called species of the genus *Narcissus* have been pronounced by some botanist or other to be hybrids of two other species. It has been said of *N. incomparabilis*, of *N. montanus*, of *N. intermedius*, of *N. dubius*, of *N. biflorus*, and others. The different species of *Narcissus* do form hybrids readily, and it is possible that some or all of these may have originated in crosses. Still, when we find that a plant has held for centuries an independent existence, and that it reproduces itself perfectly from its own seed, botanists will not deny it the right of being a species because three hundred or three thousand years ago it may have derived its first origin from a cross. That something like the species mentioned may be produced in gardens by artificial crosses may be true enough; and many similar crosses seem to be constantly produced in Nature, and to die out again. I have living in my collection from wild sources *N. pseudo-narcissus* × *N. triandrus* (several forms), *N. Bulbocodium* × *N. triandrus*, *N. pseudo-narcissus* × *N. juncifolius*, *N. poeticus* × *N. pseudo-narcissus*; of the last named I found several hundred flowering last summer in the Pyrenees. They grow mixed up with the two parents. But though they vary much, I did not find one which could have been mistaken by anyone who knows the genus for *N. incomparabilis*, which has been said to owe its origin to this cross. To return to *N. cyclamineus*, the style and stigma, and anthers and the mouth of the corona resemble *N. pseudo-narcissus*; but there are two very distinct characters which I have never seen in any of the many varieties of *N. pseudo-narcissus*—one is the reflexing of the perianth, the other the juncture of

the tube and corona, the outline of the latter bulging out suddenly from the end of the tube. This is seen in the accompanying diagrams, which are drawn in profile from exact measurement, and afford perfectly consistent characters of the respective species.

1. *N. Bulbocodum*. 2. *N. triandrus*.
3. *N. cyclamineus*. 4. *N. Pseudo-narcissus*.
The cross lines mark the juncture of tube and corona where the perianth is attached.

I have not mentioned the extraordinary form of the tube of *N. cyclamineus*, which is its most peculiar botanical character. Has the remarkable rapidity with which *N. cyclamineus* (I speak on Mr. Tait's information) ripens its seed any connexion with this? C. WOLLEY DOD.
Edge Hall, Matpits.

Dwarf Cannas.—M. Dutailly, president of the Association Horticole Lyonnaise, at a meeting held for the distribution of prizes won at the exhibition in September last said, speaking of the progress of horticulture, "The Carnation, which by some is called the king of flowers, has been greatly improved in our city, and the perpetual Carnation had its origin here." But that is not all, for we have not ceased to continue with ardent zeal to improve flowers of various kinds. One of our distinguished horticulturists, M. Crozy, has by hybridisation transformed the *Canna* into a plant worthy of the name. The tiny flowers of the parent plants have been greatly enlarged by him, and now our *Cannas* are ornamented with large and numerous flowers, brilliant like those of the *Gladiolus*, while the ample foliage of the Indian plant has been retained. Thus improved they are not only valuable garden ornaments, but also useful for indoor decoration.—JEAN SISLEY, *Mompaisir, Lyons.*

SHORT NOTES.—FLOWER.

Alpine plants—Would some of the readers of THE GARDEN be so kind as to give the names of the six best alpine plants suitable for exhibition?—SUB-EDITOR.

Saxifraga ciliata.—We have this now in bloom, and a handsome plant it is. The flower-stalks are from 4 inches to 5 inches in length, and of forced rhubarb colour, the flowers being of a whitish pink. The leaves are roundish in outline, and are from 5 inches to 6 inches in length.—W. H.

Iris reticulata.—This *Iris* possesses so many good qualities that it cannot fail to become one of the permanent adornments of cool houses, and also of any open-air garden to which it is introduced. That it produces flowers in the depth of winter under glass which, for richness of colouring, are equal to those of any *Orchid*, is of itself sufficient to entitle it to high favour; but when we find that its requirements as to soil and situation are such as can be supplied in the humblest cottage garden, it cannot fail to commend itself to all who love flowers. I find it to be most useful in 5 inch and 6-inch pots, into which I put five or six bulbs, and, if set on a shelf in a vinery or greenhouse as soon as potted in autumn, they will be in bloom in January and February. Out of doors I planted a few bulbs in a warm border in front of a vinery, and last spring they were in full bloom in March. They were left undisturbed, and I find that they are pushing up strongly, each bulb having increased to three this season. Any one wishing for a really choice spring flower to contrast with *Crocuses* cannot do better than grow a few clumps of this pretty *Iris*. Our soil is a light sandy loam, and without any special preparation this *Iris* does extremely well in it. I may add that plants of it in pots were not shaken out of the old soil until the day on which they were repotted, as I think bulbs of all kinds keep better in soil than in paper bags or boxes.—J. GROOM, *Glasport.*

Old Crimson Clove.—Why is this grand old Carnation so subject to disease? Is it weaker in constitution than the other varieties. Last autumn we entirely renewed our Carnation borders, removed all the old plants, and planted entirely with healthy young stock; and as our soil is of a heavy, wet nature, we removed the whole of it to the depth of about 15 inches, and filled up with a prepared soil, consisting of loam, leaf mould, and sand from the seashore, which on previous occasions had proved beneficial to Carnations. The whole of the plants looked healthy, and appeared to be doing well, and not in the least damaged by the recent severe weather until about three weeks ago, when it was noticed that the Old Crimson Clove began to look sickly and to die off in places. Upon examining the roots, I found a small white maggot in the centre of them. It is probably the same species as the one which has been doing so much damage amongst the Carnations at the Slough Nurseries of late. But it seems strange that it should attack this variety alone, when it is growing side by side with other varieties which, up to the present, continue to look strong and healthy, and not in the least affected; but on previous occasions here the Old Crimson has always been subject to black spots appearing on the Grass, but never on any other variety. It would be interesting to hear the opinion of some good Carnation growers on the subject.—J. C. C.

Primula obconica.—This must become a general favourite when better known. In order to have good specimens of it it should be propagated from seeds; for this purpose a plant should be set aside and only allowed to develop two or three flower-heads, picking off all fresh comers as soon as they appear. To have plants in bloom at this season the seed should be sown at the same time as that of *Primula sinensis*, and it should receive the same treatment in every way. This *Primrose* bears from twenty-eight to thirty flowering spikes at one time, and each spike carries from seventeen to twenty pinkish white flowers. *P. floribunda* makes the best plants when raised from seed and treated in the same manner as *P. obconica*, but it is greatly inferior to it in elegance. It has yellow flowers, which are produced to such an extent that the plants are almost worthless for growing a second season.—W. H.

Tropæolum speciosum.—This lovely climbing plant, which is so useful for covering walls, pillars, or trellises, has also a charming effect on the bare stems of *Roses* or those of other shrubs. It is, however, rarely seen in the south of England, and in cases in which I have seen it, it never appeared to grow satisfactorily. In northern districts and in Scotland it may be seen in its true form. We have a quantity

of it planted here against walls, and when commencing to grow we place wire netting against the walls, through which it climbs and forms a dense mass of green, studded with bright vermillion flowers. It appears to enjoy a deep, rich, and rather moist soil, and pains should be taken to get it well established and vigorous. It is easily propagated by dividing the old roots, an operation which should be done in spring before they commence to grow. When planting, place a good bed of well decomposed manure in the bottom of the pit and sprinkle a little soil over it; then insert the roots about 6 inches apart, and fill up with soil, consisting of good loam and leaf-mould. A good surface mulching is necessary, as the manure thus applied prevents evaporation during summer.—C. C. HOWLER.

ROSE GARDEN.

T. W. GIRDLESTONE.

GROUPING ROSES.

In addition to the Hybrid Perpetuals, there are a few *Roses* which, though they blow but once a year, ought yet to occupy a conspicuous position in every *Rose* garden. It is objected that beds of these will be dull and flowerless in autumn, it may be found possible to combine with them some varieties sufficiently alike to be in harmony with them, but which yet are autumn-flowerers. The obvious resort, that under such circumstances it can be only worth while to grow the autumn-blooming varieties, does not necessarily apply. For instance, who that has ever loved the name of *Rose* would be without *Moss* *Roses* in his garden? Now it is a strange thing that of all the seedlings and hybrids of *Moss* *Roses* that have been raised, though many of them flower in autumn, none excel, and very few at all approach in beauty, what is still, for lack of a better name, called the common *Moss*. It seems as if the flower-angel of the legend, angered at the presumption of the notion of trying to improve upon what he intended to be a masterpiece, had thwarted every attempt at the development of a race of beautiful *Moss* *Roses*; at any rate, the fact remains that there is not a coloured *Moss* *Rose* that can compare favourably with the common *Moss*, which, although it flowers but once a year, must therefore be planted where pink *Moss*-buds are wanted. The term "coloured" *Moss* *Rose* is used advisedly; for there is a white *Moss* *Rose* which produces buds hardly less attractive than those of the common pink variety, and which has the additional advantage of flowering again in autumn. If, therefore, this white *Moss* *Rose*, which is called *Blanche Moreau* and is one of the most vigorous and best constituted of the race, be associated with the common *Moss* *Rose*, each has a worthy compeer, and while the one that flowers but once a year cannot be dispensed with, it is not necessary that the *Moss* *Rose* bed should be flowerless in autumn. There is one other variety, albeit no autumnal flowerer, that is worthy of being grown beside the common *Moss* and *Blanche Moreau*—*Little Gem* to wit, a charming miniature crimson *Moss* *Roselet* abundantly produced on bushy plants, and eminently attractive both in bud and (unlike all other *Moss* *Roses*) also when expanded.

The *Scotch* *Roses* or *Scotch* *Briers* again make charming groups or masses, especially the less formal (not that any part should or need be formal) parts of the *Rose* garden; and these hardy *Roses* are of especial value from the fact that they will establish themselves and flourish in soils and situations where other varieties will not thrive. They look well clothing a bank or slope, their dwarf growth and innumerable flowers covering the ground admirably, and in such a position they are useful as well as ornamental, for their abundant suckers and underground stems are of material service very often in supporting the bank they grow on. The most attractive varieties are the yellow, a very hardy and free blush-white; and a fresh pink, semi-double only, but the purest of its colour; but their name is legion, and as they are so rarely grown now-a-days under names, it is not

easy to obtain particular sorts, nor to identify them except when in flower. To avoid the groups of Scotch Roses being flowerless in autumn, every fourth or fifth plant should be the Stanwell Perpetual, a charming blush-white hybrid of most delicious fragrance, and one that produces its pretty flowers at intervals throughout the season until cut off by frost.

If a representative of the old-fashioned striped Roses is wanted, there is nothing to surpass *Rosa Mundi* or Rosamond, figured and described by Redouté under the name of *Rosa versicolor*, and one of the oldest striped Provence Roses. It is curious how constantly and persistently this Rose has been called and passed from hand to hand as York and Lancaster, which is a true damask, with rather flimsy and not very striking white flowers striped with lilac or pale rose, though it is a common thing for the petals to be all red or all white without any stripe or flake. This true York and Lancaster is not by any means a variety to be selected for the purpose of making an effect of colour anywhere, but *Rosa Mundi*, which has a good white petal variegated with bright red, makes a very striking and distinctive feature when grown in a mass, as it is without the lilac shade which prevails in so many of these striped Roses and gives a group of them a dingy appearance.

So far the only yellow Rose referred to has been the yellow Scotch Brier, but for making an effective mass of that indispensable colour there is nothing among Roses that can vie with the golden glory of the Austrian Briers. Of the double varieties the best are Harrison's Yellow (still pedantically called Harrisoni in many catalogues) and Persian Yellow, each bearing a strong family likeness to the other, both having bright yellow flowers, the first being perhaps rather the stronger grower and the second rather the more free-flowering of the two. For the latter qualification, where either is obtainable and only one required, preference should be given to Persian Yellow; but Harrison's variety is said to be able to endure the murky atmosphere in the neighbourhood of large towns. Oddly enough, though both called Austrian Briers, neither of these two Roses originated in Europe, the one having been sent from Persia by Sir Henry Willock in 1837, and the other having been raised in the garden of Mr. Harrison in America, it is said from a cross between *Rosa lutea* and a Scotch Brier, about the year 1830. Neither variety requires much pruning, and both make fine heads as standards; and if plants of this form be planted in front of a high hedge of some dark Evergreen, such as Holly or Portugal Laurel, the effect of the bright yellow flowers against the glossy green background is exceedingly striking.

The double forms, however, should not be cultivated to the exclusion of the type *R. lutea*, the yellow Austrian Brier, whose single flowers are of an even more delicious shade of yellow than those of the Persian variety, and are quite capable on a large bush, or where several plants are grown together, to make a very telling display. *R. punicea*, too, whose unique and gorgeous colouring is but little suggested by the epithet "copper" Austrian Brier, is indispensable; there is nothing in the least like it in all the Rose world; scarlet does not describe its hue, which yet is not orange, and perhaps the description of it as the Rose with petals of gold lined with vermilion is not really any exaggeration. These two Roses, single-flowered though they be, should be grown in abundance, not only to make a brilliant and distinctive group, but also to supply cut flowers, a purpose for which their pure and unusual colouring renders them especially popular.

It may be worth while here to mention three or four other single Roses, by way of completing a selection of the best six sorts for growing in masses. For the beauty of its individual flowers *R. macrantha* must rank next to the Austrian Briers, although its habit of growth is not quite sufficiently erect to display its charms to the fullest advantage when it is grown as an ordinary bush;

but if it can be grown against a pillar, or, better still, be planted beside, and trained to, an ordinary foot-and-rail fence, its large, fine petalled, flesh-tinted flowers make a grand show. The best companion to it in the cut state is Hebe's Lip, which is classed as a Hybrid Sweet Brier, and which has large substantial white petals with a Picotee edge of purple. This beautiful Rose is not of climbing habit, and, though strong and of excellent constitution, has not that rampant vigour of growth which has before now been urged as an objection to some of the rubiginose. It makes a good, hearty bush, several of which, planted together, produce a better effect than a majority of the white Roses commonly grown in gardens; while a bouquet of its flowers, with those of *R. macrantha*, furnishes a combination which cannot fail to win general admiration. *R. Woodsii* produces a profusion of rosy blossoms, which render it a very pretty plant and well adapted for massing. *R. lucida* is perhaps the best of the North Americans, and a group of plants of it is certain to arrest attention at any time of the year. Its habit of growth and ruddy shoots, with its deep green glossy foliage, would make this "Rose luisante," as the French call it—worth cultivating even if it never flowered, for it is nearly an Evergreen, and its gleaming leaves do not get disfigured by mildew and such pests; but it has attractive rose-coloured flowers, which are succeeded by even more attractive deep scarlet hips, so that, although the plant does not bloom a second time, it is often gayer in autumn than many a so-called Hybrid Perpetual Rose. None of these six single Roses can be considered weedy or in any sense of the term wild garden plants; while, with the exception of *R. macrantha*, which displays itself better when afforded some slight support, all make handsome and effective groups as bush plants and are free from mildew; all are hard, free-growing, and free-blooming, and have beautiful flowers; and all will grow and flourish without any particular looking after.

Another single Rose has of late years given rise to a charming class of Roses for massing, namely, the hybrid polyanthas, which afford an excellent instance of the advantage that may accrue from the employment of Rose species in hybridisation. The original *Rosa polyantha*, one of the prettiest and most fragrant of the single Roses, is a rampant climber and not autumnal, but it is extremely hardy and produces immense trusses of bloom; the Tea-scented varieties, on the other hand, have double flowers, and are among the freest of autumnal bloomers. By the intercrossing of *R. polyantha* and the Teas a progeny has arisen, displaying the main characteristics of both parents, namely, the hardness and floriferousness of the former combined with the double flowers and thoroughly perpetual character of the latter. Most of these hybrids closely resemble the original *R. polyantha* in everything but stature, for instead of being gigantic climbers they hardly exceed 9 inches or a foot in height. This does not apply to a recent seedling of M. Lacharme's, which, however, was the outcome of a cross between *R. polyantha* and General Jacqueminot, and not a Tea-scented variety. The best of the varieties is Mignonette, which produces its great trusses of fresh pink flowers almost without intermission from June till November; it makes a compact bushy little plant, and a mass or broad edging of it is always attractive, being rarely without flowers, which, moreover, are able to endure exposure to considerable rain or hot sunshine without disfigurement. Two of the best of the white varieties are Anna Marie de Montravel, each of whose blossoms is a singularly perfect rosette, and Paquerette, which, oddly enough, like Mignonette, is called by another flower's name; Paquerette being the little white Easter Daisy, and probably also used as a pet name. The inflorescence of Perle d'Or inclines more to the branching type of the Teas, but its Madame Falcot-coloured flowers are charming, and it is so far the only yellow variety.

There is one other Rose which is not included

in any of the universally recognised sections, although it is an eminently desirable plant and continuous bloomer; this is *Rosa clinophylla* fl. pl., whose numerous large double blush-white flowers make a delightful group, and for whose non-cultivation the fact that it is neither called a Hybrid Perpetual nor a China nor by any other nickname is not sufficient excuse.

Of the Bourbons, the best for massing are Armosa (syn., Setina), pink, Queen (fawn), and Souvenir de la Malmaison, whose blush flowers, however, often fail to open clean in early summer and are too liable to be spoilt by wet in autumn; but of the Chinas, too many can hardly be planted, and of such varieties as the common pink, Cramoisi Supérieure, the pretty pale Mrs. Bosanquet, and the dazzling Fabvier, effects of colour may be made in the roserie which will be in evidence during fully six months of the year.

GARDEN FLORA.

PLATE 585.

CELOGYNE CRISTATA MAXIMA.*

THE ever-popular *Cœlogyne cristata* is perhaps the best known of all showy garden Orchids, for ever since it was introduced five and forty years ago it has been grown in all good gardens. A lovelier Orchid does not exist. The graceful way in which the long, pendulous spikes of flowers are produced adds a charm to the chaste beauty of its snow-white blossoms. Upon this identical species Lindley founded his genus *Cœlogyne*. This was in 1825, but the plant was not introduced until about ten years later, and in the year 1841 the first flowering plant was seen in this country. Mr. Barker, of Birmingham, at that time one of the chief among the few Orchid growers in this country, exhibited a fine specimen of the crested *Cœlogyne* before the London Horticultural Society, which held its meetings at that time in Regent Street. This Orchid captivated everyone by its exquisite beauty, and Mr. Barker was awarded a silver Banksian medal for the plant. Since then we may say that the *Cœlogyne* has been an established favourite in gardens; indeed, it is now as indispensable to a gardener in spring as the *Eucharis* is in winter. In gardens where Orchids are not made a fuss with, you see this *Cœlogyne* grown well in company with a few other old Orchids like *Dendrobium nobile*, *Phaius grandifolius*, *Cypripedium insigne*, and others of proved excellence for cut bloom. For many years this Orchid was cultivated before any variation from the original type was noticed; then came larger flowered forms; then one with pale lemon-yellow on the crest instead of orange-yellow; and then the snow-white variety called *alba* or *hololeuca*; and lastly, the magnificent form called *maxima*, which is well represented by the accompanying plate. Every variety is so beautiful in itself that it is a difficult matter to say which is best. Many consider the pale yellow crested form the loveliest, as the yellow, being so delicate, harmonises so charmingly with the white sepals and petals. It is named *Lemoniana*, after Sir Charles Lemon, not in allusion to the lemon-yellow crest, as is generally supposed. It is also, but less frequently, called *citrina*. This is still a rare variety, and plants of it in the auction rooms, particularly if in bloom, always fetch a good price. The pure white *hololeuca* is yet as rare as it is lovely, and tiny plants sell for several guineas apiece. There is not a trace of colour in the flower; indeed, it is one of the few only absolutely pure white Orchids in cultivation. The form of the flower is quite different from that of the ordinary type,

* Drawn for THE GARDEN by Mr. Moon in Mr. Sander's nurseries, St. Albans, on May 20, 1883, and printed by G. Severyns.

and this, combined with its distinct style of growth, which is somewhat creeping or stoloniferous, inclines us to regard it as a distinct species. One can single a plant of it out among a crowd of plants of the other varieties. Now we come to the large-flowered forms, variously known under the names of the Trentham, Chatsworth, major and maxima varieties. The Chatsworth form is very fine, large in bloom, broad in sepal, and long in spike, and so is the Trentham; in fact, it is a difficult matter to tell the difference between them. The Chatsworth form is a wild variety found and brought home by the late Mr. John Gibson (Battersea Park) when collecting plants in his young days in India for the Duke of Devonshire. The maxima variety is what we ought to talk about most, because it is generally admitted to be the very finest yet seen. As may be seen by the plate, the flowers are large and broad-petalled, and the spike carries five and six flowers each, while it is otherwise distinct, particularly in the large truncate bulbs. This form is also known among Orchid growers as the St. Albans variety, on account of its having been distributed by Messrs. Sander, of the St. Albans Orchid nursery. It is a scarce and most expensive plant at present, but being a strong grower and tolerably easy to propagate by division it may not be so scarce in a few years. It is a great chance if such a fine form as this turns up again. Those who love the old form will long to grow this new variety, as it is so superior to it.

COLOGYNE CULTURE is now so well understood and practised, that it would be almost an insult to our readers to describe it in detail. The glorious specimens with which one meets in all parts of this country afford evidence of this, and few Orchids can be grown into what are popularly called specimen exhibition plants with such comparatively little trouble. This *Cologyne* is essentially a cool-house Orchid—that is, it abhors a high and dry temperature. It may be grown to perfection in a cool, moist greenhouse, not a draughty place, as most greenhouses usually are, and during the time it is making its growth—that is, after the flowering time, which extends from about January to March—it can scarcely be over-watered, provided the drainage of the pots or pans is good. This plant is so sensitive to injury by dryness, that when once it has suffered from protracted drought the bulbs shrivel and require a long time to recuperate themselves. The same thing occurs after dividing the bulbs for increasing the stock, as is done in some places, as the roots dislike disturbance. The bulbs are apt to become overcrowded, and will, if left unmolested, grow one upon the other in a confused mass. Instead of dividing the root-stock and so thinning the bulbs, a better plan is to cut away the old and useless bulbs, leaving the young leaty bulbs ample room to develop. The best time to pot *Cologynes* is in spring, as soon as the flower crop is past. The soil should consist of good fibry peat, mixed with a good proportion of fibry loam and Sphagnum Moss. Pans are best suited for *Cologynes*, as the bulbs then have more surface upon which to increase. Large specimens, 3 feet or 4 feet across, are invariably grown in pans about 9 inches deep.

C. cristata is a native of Northern India, where it grows wild among the hills of Nepal and Sikkim, at elevations of 5000 feet to 8000 feet. It is found, travellers tell us, mostly on trees and rocks, always fully exposed to the sun; and therefore, from this fact cultivators may take the hint not to shade too heavily.

Pelargonium De Lesseps.—Although this variety has been raised for some years, it is still considered to be one of the best for winter flowering. We saw it growing

side by side with *Vesuvius* in the nurseries of Messrs. Hawkins and Bennett, who consider it quite equal to that variety for yielding cut blooms. The flowers are bright scarlet, and produced in profusion.

FRUIT GARDEN.

W. COLEMAN.

GRAFTING VINES.

My thanks are due to "Hortus" (p. 166) for having directed my attention to a sentence in my paper upon this subject which he thinks may puzzle people. The sentence in question runs as follows: "If the stock is very young, the joining of the inner bark of the one to that of the other will not be difficult, but when the stock is old and rough some care will be necessary, otherwise the two will not meet, but overlap, when a perfect union may be doubtful." Further, he assumes that I have slid out of the vineery into the orchard. Such, however, is not the fact, as readers will gather that I thought it necessary to point out the danger of adopting in the vineery a method which usually succeeds in the orchard. From a physiologist's standpoint "Hortus" is doubtless right, but from a practical operator's point of view I venture to think I am not wrong, for, granting that the Vine is endogenous and has no inner bark, externally there is a limit to the sap vessels not infrequently protected by flakes of dry bark more than half the thickness of the scion. Allow one side of the scion to overlap this dead matter, and the chances of a perfect union are very much lessened; but unite the living bark of the one to that of the other, and the operator, who in nine instances out of ten attaches the graft to one side of the stock, derives full benefit from the doubt as to whether the bark or the wood are the active agents in forming a perfect union. In my own practice I have always attached the scion to the side of the stock, and when the latter has been very large I have put on two, one on either side for the twofold purpose of securing two strings to my bow and getting the porous wood quickly covered and protected from the action of the atmosphere. As to whether half the stock and a like portion of the scion are cut away, I think matters little, always provided the operation is performed at the proper time, *viz.*, after the stock is in full leaf, and the two barks or outer coverings are neatly joined at the base. I should not, however, like to trust to a small piece of wood placed immediately over the pith of the stock unless the heel of the scion overlapped the external covering of the stock. In the example of cleft-grafting to which I made allusion, the stocks, to the best of my recollection, were quite 2 inches in diameter after the Vines were headed down. Two grafts, one on either side, cut wedge-shaped were lightly driven home, but, notwithstanding the fact that the pith was split through, certainly they did not touch it, and they grew as freely as the best bottle grafts I ever saw put on young Vines.

BUD-GRAFTING is a very neat and expeditious mode of transforming an established cane into a fruit-bearing Vine in one season, and may, I believe, be successfully performed in the autumn as well as in spring. It is not, however, so much practised as it deserves to be, as many bare parts of old rods might be refurbished where a change of variety is not thought necessary. "Hortus" having so lucidly described the method which he so successfully practised in April, when his Vines were in full growth and his buds, as a matter of course, ripe and to a certain extent dormant, the remainder of my remarks will be devoted to autumn grafting. Some years ago, when the much-abused and imperfectly-understood Madresfield Court Muscat was disposed of by my friend

Mr. Cox, the late Mr. Stevens, of Trentham, took Grape growers by surprise with a full crop of Grapes the following season. The method he adopted was bud-grafting in the autumn, whilst there was a sufficient flow of sap going on to form cambium and so complete the union. The buds in his, as in all cases of the kind, would be taken from young rods still growing, but on the point of ripening, and, being nearly perfect, would remain dormant throughout the winter. Unlike the Rose or the Peach, it is unnecessary to remove the wood from the shield; nor must the leaf attached be injured. When neatly and accurately let into the rod by taking a corresponding piece of bark and wood out just below an eye, the bud, about 2 inches in length, must be firmly tied with soft bast or budding yarn and protected with Moss, which must be kept damp until the union is complete. When the rod shows signs of ripening its foliage, and there is no longer any danger of the bud breaking, the shoots beyond must be shortened back to two or three buds and left for the winter. As soon as the sap begins to move in the spring, breaks from the eyes left on the stock will require close pinching, and when the inserted buds get into free growth their entire removal will become necessary. If it is thought desirable to put a number of buds on a cane—which, by the way, should not be old—they may be let in alternately a foot or so apart, care being observed as regards the protection of the buds and foliage of the Vine, as well as of the leaves attached to the buds. When all is finished, light, shading, and syringing two or three times a day to keep the Moss damp, will facilitate the completion of the union.

— After a very short trial I gave up grafting Vines, and now whenever we want to work any other variety on to the permanent Vines, it is always done by inarching. By this method a much more satisfactory union is made, and no time is lost. In fact, the advantages are all on the side of inarching. Suppose a scion is grafted on a permanent Vine this spring, it might not become a fruiting cane during the following season; but in the case of the inarched Vine, if properly managed, a fruiting cane is sure to be the result. The operation is so simple, that almost anyone may perform it successfully. The Vine on which the inarching has to be performed should have a shoot trained up from near its base, and the Vine to be worked on it must be grown in a pot. When both have made shoots about 1 foot long, the pot Vine is placed close to the stock, a slice about 3 inches long is taken from the side of each growth, cutting with a sharp knife to the centre; the two are then tied closely together with a strip of bast. The top is also pinched off the shoot which sprung from the permanent Vine, and the new one is trained up in its place. The two shoots should be tied loosely together above and below the union. In three weeks the bast must be loosened, but it must be carefully done, as the cut portions may separate; indeed, I do not remove the bast altogether until the end of the season. The Vine in the pot is also cut off gradually by cutting a notch in the stem close to the union and cutting it deeper at intervals of two weeks until it is cut quite through.—J. D.

Bush fruits.—Gooseberry bushes seem in this locality to have passed through the hard weather so far very well. Tomtits and other ravenous small birds have been either scarce or otherwise fed, as their customary attacks upon the fruit buds seem to have been lacking. There is time yet for mischief, it is true, but with a little open weather the buds will soon burst, and will then be beyond the reach of such depredators. Currant bushes rarely suffer so much as Gooseberries do, but all seem let alone this season. So far that is hopeful. Still further, all the buds yet remain dormant, the effect, no doubt, of a lengthened period of cold, but specially promising because we have seen bush buds in some previous years quite in leaf early in February. Black Currants have not been heavily fruited for two years, and on these the

buds are stout and vigorous. In the case of other bush fruits there is not such development, but it is not possible to tell whether or not buds will prove productive for some time after they have burst into leaf. There is a lull just now in the planting of breadths of bush fruits, for prices have not been encouraging of late.—A. D.

HOME-GROWN V. AMERICAN APPLES.

Now that American Apples are being brought into this country in quantity and taking the place of our home-grown fruit, it may be well to make a note or two of several varieties of the latter that may be had in good condition during this month and the next. If fruit-growers would only bestir themselves, weed out old and useless varieties and plant sorts that would come in, in quantity at a time when American varieties are a glut in the market, I have no doubt that home-grown fruit would soon take the place of foreign fruit, and fetch more remunerative prices. The reasons for this supposition are not far to seek. The American fruit has to be conveyed long distances, both by land and sea, and there is not the slightest doubt that the fact of its being packed so closely in barrels causes fermentation, and thus robs it of any fine flavour which it may have had. American fruit has little briskness, Newtown Pippins excepted, and always seems flabby and soft. Home-grown fruit, on the other hand, as, for instance, Cox's Orange Pippin, Ribston, and Blenheim Orange, is just the reverse. If people would only take the trouble to examine fruits as to quality and not look so much to high colour, matters might be different. Only the other day I was privileged to see a collection of Apples grown in a large fruit nursery in the neighbourhood of London. This nursery is quite close to the Thames and surrounded by large gas factories, yet, in spite of its position, it produces excellent fruit. The soil is sandy and light with an understratum of yellow sandy gravel, through which the water percolates freely. The fruit trees are all small and take up but little room, being for the most part worked on the Paradise stock. In looking over the produce, now, of course, in the fruit-room, I found grand samples of the following, viz.: *Dessert Apples*—Boston Russet, Braddick's Nonpareil, Claygate Pearmain, Coole's Seedling, Cockle Pippin, Court Pendu Plat, Cox's Red-leaf Russet, Duke of Devonshire (very fine), Dutch Mignonne, Fearn's Pippin, Golden Russet, King of Tomkin's County (a handsome, highly-coloured variety of American origin), Lamb Abbey Pearmain, Lord Burghley (very fine, will be in condition up till May), Mannington's Pearmain, Northern Spy, Ribston Pippin, Scarlet Nonpareil (handsome fruit), Stamford Pippin, Sturmer Pippin, Syke House Russet, Wyken Pippin. *Kitchen varieties*—Alfriston, Besspool, Bramley's Seedling, Baumann's Red Winter Reinette (a very handsome variety), Betty Geeson, Bismarck, Dumelow's Seedling, Gloria Mundi (quite sound and good), Graham's (cooking or dessert) Lord Raglan, Hambleton Deux Ans, Hereford Pearmain, Norfolk Beaufin, Northern Greening, Royal Russet, Striped Beaufin, The Sandringham, Yorkshire Greening. These varieties were all in a grand state of preservation, and several of them, notably the Beaufins, will last up till May. T.

Golden Queen Raspberry.—Among new varieties of fruit that are prominent in the trade this season is the Golden Queen Raspberry. This variety is supposed to be a seedling from the Cuthbert. It would appear from the claims made for it by those interested in introducing it that it has some unusual merits, for, while it is said to have "proved of iron-clad hardness," and thus is suited to the coldest of northern climates, it also finds favour in the Southern States, where, heretofore, only the Black Caps have succeeded well, the heat being too great for the red varieties—"flattering reports of it have been received" from Maine and Minnesota to Florida, Louisiana and Texas. Greater popularity than this could not be hoped for. The berries are said to be of large size, exceeding those of the Cuthbert, and of high quality, golden yellow in colour. The canes are strong and exceedingly productive. Mr. Theodore F. Baker, formerly president of the New Jersey Horticultural Society, says: "I am much pleased to

state that the favourable impressions I had of this Raspberry last year are confirmed and strengthened by my observations this year. It certainly is a most wonderful plant. Strong, thrifty, and healthy, while, withal, the canes had drooped with their enormous crop of fruit, which is large in size. Some berries I measured were 1 inch across, while many would cover seven-eighths of an inch in diameter. As to the quality, I consider them the best of all the Raspberries. Those I ordered sold readily, and were pronounced superior to other kinds in the market, both for quality and size. The berries were in good condition, convincing me that they will bear transportation with the best of the Raspberries."—*Vick's Magazine*.

STRAWBERRIES IN POTS.

COMPLAINTS among gardeners are not uncommon at this season of the year as to their Strawberry plants producing abortive flowers, either causing the entire or partial loss of the crop. The question arises whether such disastrous results may or may not be entirely avoided. It is only the earliest crops that are likely to be injured, but, as a rule, these are of the most value. For many years I have given attention to the cultivation of Strawberry plants in pots, and have had ripe fruit about the end of February, but to obtain such results the plants must be subjected to good cultivation and careful management through all the details of their culture. If there are any gardeners lamenting the loss of their crops during the months of March and April, it is possible that failure may be avoided next year by attention to the following details. In the first place, the plants intended to be forced early should be propagated as early as possible the previous season by pegging the layers into small pots from the middle to the end of June, and I would advise the culture of Black Prince for the earliest batch of plants, to be succeeded by Keen's Seedling. It does not always follow that because a Strawberry may be excellent for early fruiting if planted out of doors that it is of equal value for pot culture. Failure may result from acting on this assumption. Two weeks after the layers have been placed in the pots they may be cut from the parent plant; place the plants in an open, sunny position, sheltered a little from the north and east; in two or three weeks more the Black Prince variety may be transferred to 5-inch, and Keen's Seedling to 6-inch pots.

For potting soil use good decayed turfy loam, with a third part of stable manure, and in potting the plants ram the compost quite firmly with a wooden rammer. They may then be placed in the same position as before, but in order that each plant may be exposed to the influence of light and air as much as possible, I place each one separately on a brick. If the leaves are kept free from mildew and a plentiful supply of water is given, strong fruitful plants are sure to be produced. It is very easy to keep them clean by daily watchfulness. Mildew, as also red spider, may cause much damage. Our plants of Black Prince were attacked by mildew last year, and before I was aware of it they experienced a very serious check. I had them dusted with sulphur, which destroyed it at once; but the leaves were so badly injured that many of them shrivelled up, and I fear we will see the effects of this presently. The plants may be left out of doors until the end of October.

After that time take them into some cool house or shelter from rain by frame lights. It is also of the utmost importance that the plants should be placed near the roof-glass when forcing commences, and the temperature must not be higher than 15° at first, rising 5° in two or three weeks, and 5° more in a month or six weeks from the time of starting, but not more than 55° at night until the flowers open, and they will set better in this temperature than in a higher one. Up to the time the flowers open a moist atmosphere may be kept up, but at flowering time a dry atmosphere is best. The blossoms should be brushed over once every day with a soft brush or a portion of rabbit's fur tied on a stick. In all the stages of the plant's growth water should be freely supplied at the roots, and when the fruit is set the plants ought to be well syringed daily to prevent red spider. The minimum temperature should be 60° to

65° when the fruit is well set. I ought to add that as soon as it begins to colour it is desirable not to give too much water, otherwise the flavour will be impaired. The fruit must also be thinned out. A good plant of Black Prince will bear a dozen or fifteen good fruits. J. DOUGLAS.

FILBERTS AND COBS.

As one who has been for the past few years favoured with some Kentish-grown Cobs and Filberts, and can appreciate their fine quality, flavour, and dimensions as compared with Spanish Nuts, I can join heartily with Mr. Coleman in wishing to see the cultivation of these hardy fruits largely extended. No doubt Kent owes its reputation for these nuts to the excellent cultivation bestowed and admirable system of pruning adopted in that county, but what is possible there is equally possible elsewhere. Mr. G. Bunyard, in his admirable little book on fruit farming, refers to the fact that considerable breadths of nuts are grown in close contiguity to the Hop gardens, and that it is needful to gather the fruits even ere ripe lest the pickers should plunder the trees. That is a difficulty which need not exist in other parts of the kingdom, where there may be found warm sites, shelter, and deep rich soil in abundance. Probably the chief difficulty would be found in vermin, squirrels especially, but if good class nut-growing be undertaken, it should be done well, and ample protection from vermin should be assured. Over how many acres of woodland carrying overhead fairly good timber are there beneath common Hazels used only to furnish fagots, hurdles, Pea-sticks, &c., none of a very profitable kind, and yet occupying land where cultivated Nuts would thrive admirably. How much better would it be that land should be thus devoted than given over to the keeper and the pheasant.

It is specially important that nuts and Filberts should have some little overhead shelter. We have this season, for instance, seen Filberts in wonderful bloom during February, and whilst the bloom was at its best we had several days of bitter east wind and nights of intense frost. It seems impossible for the bloom to have survived such weather, but if it is found to have done so, then must it be classed as hardy indeed. Ordinarily we may look for good nut crops four seasons out of six, and that is a good average; but it is evident that, with the bloom opening so early and in such an exposed manner, there being no foliage to shelter it, that the chances are rather against a crop than favourable if hard weather prevails at the blooming period. Probably if we could ensure freedom from late winter and spring frosts we should enjoy the most abundant fruit crops in the world. It is weather which so largely handicaps our home fruit trade. It has been stated on authority that we exported small nuts to America and elsewhere to the extent of nearly £60,000 worth in 1882. If that be the case, and the nuts were of home growth, it is a surprising statement, and indicates that we must have greater breadths devoted to the culture of small nuts than is usually imagined. But it may be that some of this large export were of previously imported stocks, perhaps the best selections from Spain. On that head no information is given. Still, landowners of all classes should be encouraged to plant the best class nuts, whether Filberts or Cobs. The ground between the plants may be utilised for vegetable crops for some few years, but once the bushes have filled out, then the nuts will appropriate all vacant room. It is needful to show patience, as even well-prepared plants from the nursery some three years old still require some half-dozen years ere they become productive; but, as the old adage says, "everything comes to him who waits," so also will crops of nuts. Mr. Bunyard specially favours the Lambert Filbert, or true Kentish Cob, as being very prolific, hard-shelled, and therefore little affected by vermin; it blooms rather later than does the old Kent Filbert, which is an undoubted advantage, although the latter is rather the best flavoured. Webb's Prize Cob also obtains high praise as a very fine variety, but hardly cheap enough yet for very extensive planting. The Cosford is pronounced to be thin-shelled, a recommendation of it at once to mice and squirrels. It

produces catkins profusely, and should be planted here and there amidst other harder-shelled kinds to promote fertilisation of the female blooms. It is very evident that we have ample room for much wide small-nut cultivation. A. D.

FIGS IN THE OPEN AIR.

Now that all kinds of hardy fruits are being more thought of than at any time since the rage for building fruit houses set in, the Fig may come in for a fairer share of attention than it has had. At present Figs are cultivated principally on the south coast, but if the attempt was made in an intelligent manner much further inland, I am of opinion that success would in many instances result. The true cause of so many failures is the unripeness of the wood, this being both unproductive and very liable to destruction by severe frosts. The trees are grown too strongly—this, accompanied by a free use of the knife and close training to the walls, being the opposite of what is really required. Ordinary garden soil is usually much too rich for Figs to root in: what they should have is fresh loam and abundance of chalk or mortar rubbish. In districts not considered favourable to Fig culture, the hottest corner in the garden—this usually being the angle formed at the junction of walls facing north and east respectively—should be devoted to them. Both the surface and sub-soil ought to be removed 2 feet deep for at least a radius of 6 feet, plenty of drainage, in the shape of broken bricks or stones, with a good outlet being thrown in, and on this some rough material. One part in three of the compost should consist of either chalk or mortar rubbish, and if fresh loam be scarce, a portion of the common garden soil may be substituted. This, being made firm, induces a sturdy, fruitful growth not easily altered by either neglect or too close attention. Some of the finest Fig trees to be seen in England were at one time growing against a railway embankment almost beneath the Shakespeare Cliff, near Dover. They were planted by a fisherman and his sons, who occupy a strip of land reclaimed from the sea. The greater portion of the soil they had to root in was brought down from the cliffs in baskets, and, as far as I could judge, seemed little else than chalk. Nor did a little salt water appear to injure them, as very high tides frequently saturated their little borders. An exceptionally rough sea, which did so much damage on the south coast, completely cleared away the greater portion of the border formed in such a laborious manner, and only one tree is now alive. Plenty of fine fruit from those roughly trained trees have reached the London shops, and from 4s. to 6s. per dozen was the usual wholesale price at Dover. When I saw the trees they were at their best. They appeared to have reached their maximum size, as none of the branches at that time grew more than 6 inches in length, but this growth was nearly the thickness of a man's forefinger and very short-jointed and firm. It is this short-jointed growth that all must secure if possible. In other parts of Kent and Sussex I have seen trees nearly as sturdy in habit, but in every case they, like the Dover trees, were only roughly trained. For a few years it is necessary to neatly lay in the leading branches, but when once a good space is covered, they ought not to be treated like Peach trees. All the principal branches must be strongly secured to the walls, but the points ought not to be confined. Being allowed to grow out from the walls checks soft useless growth, and all that is necessary is to keep these shoots well thinned out to ensure good crops of fruit. Some growers are inclined to go to the other extreme, nothing in the shape of pruning being attempted. In this case a thicket of growth is formed, more especially on the top of the walls, the consequence being that only the outer portions of the trees are fruitful. The proper course to pursue is to annually thin out and tie, or otherwise strongly fasten, in the branches, the points being allowed to spring out about 1 foot from the wall. Trees with a clear stem are preferable, those being less liable to throw up a quantity of sappy suckers. If at any time the base or centre of the

tree becomes somewhat naked, some of the main branches may be freely shortened back, this being followed by plenty of fresh growths, which in time become hardened and fruitful. On no account should the points of the fruiting shoots be shortened, as these only can be relied upon to bear fruit. When the trees have arrived at a free-bearing state they require an annual surface dressing of manure, lightly forked in any time during the spring months, this being also the best season for either planting young trees as supplied in pots by nurserymen, or for lifting and replanting old trees that are not found sufficiently profitable as they now are. The Brown Turkey is the favourite variety for all positions, and I have gathered many baskets of fruit from standard trees of this hardy sort. The Brunswick, as far as the foliage is concerned, is a more handsome variety, but even in favoured localities it is very shy-bearing. For my own use the preference would be given to the White Marseilles, this small fruited sort being delicious if allowed to hang on the tree long enough. The description given of Castle Kennedy may tempt others, as it once did me, to give it a trial, but those who are in the habit of eating the fruit grown in their own garden will soon get rid of it again. The fruits are plentifully produced and exceptionally large, but they crack badly, and are rarely fit to eat.

W. I.

HOME FRUIT NURSERIES.

If landlords really want to see their tenants prosper they should set about supplying them with good fruit trees, on condition that they carefully plant and cultivate them, and leave them in good order at the expiration of their tenancy. On all large estates there are nurseries for raising forest trees, shrubs, and hedgerow plants, and by a little enlargement fruit trees might easily be added. If small holders of land or cottagers could get a supply of young fruit trees from the estate nursery, a great impetus would be given to fruit culture. There are no better cultivators of vegetables to be found than cottagers; but, as regards fruit, the majority are quite at a loss as to what sorts to grow and what to avoid, and this is one of the rocks on which the inexperienced split. If they saw the Blenheim Orange spoken highly of as an orchard tree they would at once suppose that it would be suited for small gardens in the form of a bush tree. There is, indeed, much need of sound teaching on such matters before we can hope to see the country covered with well-stocked orchards. The present state of our laws relating to land are so unsatisfactory, as to deter tenants from embarking in any expenditure which they can avoid. Landlords might therefore find the distribution of good fruit trees a really profitable investment. We frequently hear it stated that corn-growing does not pay, and vegetables are already sufficiently abundant. What, then, can we grow to keep the land in cultivation? The answer is clear, viz., grow fruit of the best kinds only. In no other way can we get the bulk of the fruit trade back into our own hands and thus save the country millions of money. Those who are willing to supply the requisite skill and labour have in many cases not got the necessary capital to invest in tree-planting, or if they have, their holdings are of too precarious a character to warrant any outlay in that direction. It is distinctly therefore the owner's duty in this case to supply what may be needed, and the best way to do this is from a home nursery in which the best sorts of fruits have been proved and made ready for planting. That orchard crops do pay better than most other crops is certain. To prove this we have only to take the average prices realised in Kent and other counties, where crops are sold on the trees, and compare them with those obtained for corn.

JAMES GROOM.

Gosport.

SHORT NOTE.—FRUIT.

Lane's Prince Albert Apple.—A better Apple than this cannot be desired for cooking, and it is in prime condition now (beginning of March). It is selling in Covent Garden Market at the rate of 9s. per bushel.—E. S.

SOIL FOR MELONS.

GARDENERS, if not exactly called upon to make "bricks without straw," are very frequently under the necessity of adopting various makeshift practices without any credit being given them for the same. If they succeed, all well and good; if they fail, they have to bear the blame. One of the greatest difficulties in the majority of gardens is that experienced in procuring suitable soil for all purposes, turfy loam, considered indispensable, being frequently absolutely out of the question. Melons have to be grown in a variety of composts, but if employers knew how much the character of the soil determined the quality of the fruit obtained, I am convinced they would consent to and even insist upon the best for the purpose being employed. In the course of my gardening career I have assisted to grow Melons in common garden soil, in a compost of turfy loam and leaf soil, in almost solid clay, in a mixture of clay and light turfy loam, in fresh turves, and in light fibreless loam, with fairly good results in every instance as far as the quantity and appearance of the fruit were concerned, but the quality varied surprisingly. A good Melon (and by this I mean a fruit that is readily eaten without plenty of sugar to render it palatable) is rarely if ever obtained from plants that rooted principally in any light or brown loamy compost. It is the loams of a clayey nature that produce the best Melons, a fact better understood by the past generations of gardeners than by the majority of those at present in practice. All cannot obtain clayey loam, but if the loam available is of a loose or light nature, pulverised and well-dried clay should be prepared and liberally added to it. I have known instances where a heap of clayey sub-soil, wheeled out from the foundations of a large house, was for years drawn upon for mixing with the Melon compost with the best of results. A loose rich compost induces the formation of rank, unfruitful growth, and what fruit may be cut is certain to be of poor quality. A solid and comparatively poor mound of soil has a contrary effect in the first instance, but, with the assistance of liquid manure and water in abundance, is quite capable of supporting a heavy crop of highly flavoured Melons. Modern cultivators certainly succeed in growing extra fine Melons, but these compare very unfavourably with the solid little fruits that used to be grown in ordinary frames on hotbeds in such abundance. Quite recently I had an opportunity of looking over a number of prize cards won by a gardener at several local shows. Nearly every season he had won first honours with Melons in competition with gardeners from larger places. It is a case of frame versus house culture, the former having the advantage. I examined my friend's soil and found it of a decidedly clayey nature with very little fibre in it, and no manure is added. Our best fruits have always been cut from plants rooting in fibrous clayey loam skimmed off the surface of pasture-land, to this being added a little fresh lime at the rate of an 8-inch potful to 2 bushels of soil. Unfortunately, our supply of this good Melon soil is cut off, and we, in common with only too many growers, have to substitute anything we can get. I can readily sympathise with gentlemen in their objection to park or pasture land being stripped of its most valuable surface soil, especially seeing that in a great many instances no attempt is made to compensate or restore the land to something like its former fertility. Wherever turf is removed for any purpose connected with horticulture, those responsible ought to replace it with garden soil, making this firm, and sowing a good mixture of Grass seeds. If this is rolled occasionally, and cut or fed down, a good turf will soon be formed; whereas, when the ground is simply cleared of turf and left to take its chance, nothing but weeds will result. Clayey loam, being unsuitable for potting, not suiting even Cucumbers, very little of it is needed annually. If, therefore, the owners of land object to the turf being entirely removed, they may yet allow a small portion of the soil underlying the turf to be dug, and this I hold to be good material for Melons.

Our plan is to line out the turf in the same way as if we intended to entirely remove it. The turving iron is passed under at a depth of about 2 inches, thus admitting of the strips being rolled back without finally detaching it. After about 2 inches, or rather more in some cases, of the soil have been removed and replaced by garden soil, the turf can be returned to its original position and well beaten down. In this manner good Melon soil can frequently be obtained without giving offence to anybody.

W. I.

Keeping Apples.—I have made a very fine cellar, well drained, paved and provided with bins for fruit and vegetables, and yet it does not answer for fruit. Apples that should have been sound and solid now, were almost dried up two months ago, and Potatoes are growing freely. Would it pay to cut a door through the present cellar wall and make a sort of underground cave, without light or ventilation in which to store the barrels, bringing them out just as needed? Or can I make entirely outside a cistern-like room, letting the barrels down into it from above? Kindly state what conditions are necessary for the keeping of fruits, and how they can be secured most economically.—J.

* * The first and most important requisite for the successful keeping of Apples is a low temperature—one within a few degrees of freezing. If this can be secured, it does not make much difference as to the amount of moisture or dryness in the air. But if the apartment is quite warm, the fruit will rot if too damp, and shrivel if too dry. What you most need probably is to control thorough ventilation, so that cold air may be let in when the days are cold, or during cold nights, and the room kept closed and cool in warm days. By the use of thermometers and proper attention, you may maintain constantly a low temperature. If the temperature is uniformly at 35°, you cannot fail to keep fruit well. Windows on opposite sides, which may be opened and closed at will, the sash either sliding or hung on hinges, will answer the purpose. The close, dark apartment you propose to make could not be kept cold enough.—*Country Gentleman.*

SEASONABLE WORK AMONG FRUITS.

PINES.

EARLY started Queens, if not already in fruit, will soon be showing, and as this is the most critical stage in their culture, a little extra attention just now will be well repaid in the long run. Bottom heat from artificial materials being so essential to their very existence, this must be kept right, be the means hot water alone or hot water and fermenting matter combined. Leaves or tan are generally used, and where the first are plentiful I question if there is anything to beat them, as every stage of decay through which they pass gives life and vigour to the Pines, and they form an indispensable article in the potting shed afterwards. Moreover, Oak and Beech leaves well harvested are always dry and warm, and ever ready to fall back upon when fermentation in the pits is on the decline. This state in the earliest Pine house as firing slackens is not unlikely to happen, and the young roots upon which so much depends being soft and tender, renovation should be performed in anticipation of their wants, not by disturbing the pots if it can be avoided, but by setting and packing them in position, by giving the old dry plunging material a good soaking with hot water and filling up to the rims with sweet, well-worked leaves. This plan, without endangering the crock roots at a critical time, will give an impetus to the fruit, and most likely suffice for the whole season. But the question may be asked, Where are we to draw the line, as different growers recommend heats varying from 100° down to 75°? Of the two, many would prefer the latter, but if I might venture a definition I should be inclined to say 85° as the mean where racing against time is not an object, and the best of all

methods growing into fruit-bearing can be practised.

Watering.—Of equal importance is the application of water to the roots, for, much as the Pine enjoys tropical heat and an abundance of atmospheric moisture, the leathery texture of its leaves does not favour rapid exhalation. Still, water must be given to the roots, and as newly started plants are generally wintered on the dry side, the first liberal supply of water should be given as soon as the fruit is visible. From this time forward each plant should be examined individually, and, whilst dribbling is avoided, a sufficient quantity to moisten every particle of soil should be given, when, to the uninitiated, the ring of the pot, to the experienced, the feel of the foliage, even in the dark, render watering necessary. As days increase in length and the sun gains strength more water may be given, but the proper strength—be the plant a newly-rooted sucker or a pot-bound fruiter, be the season summer or winter—should never be departed from, as indiscriminate watering results in the loss of roots, in untimely starting, in black hearts and inferior quality. Now all the plants are on the move, the temperature may range from 66° to 70° by night, with a rise of 10° to 15° on fine days, always with a little air and 90° with sun-heat after closing. Overhead syringing before the plants come into flower is perhaps most honoured in the breach, as an abundance of moisture can always be secured by damping the walls, and the stem-roots can be fed by syringing into the axils of the lower leaves and over the surface of the bed with warm diluted liquid when the temperature is rising.

Successions.—When all the plants intended for this year's fruiting have been top-dressed and disposed of for the present, the potting of those occupying the succession pits must be taken in hand. As these will take the place of fruiterers recently moved forward, thorough cleansing, scalding, and limewashing must precede the preparation of the bed. It does not often happen that a pit becomes quite clear of plants; therefore when it does, the war should be carried to its lowest depths, as crickets, cockroaches, and woodlice—three troublesome marauders—can then be greatly reduced, if not entirely destroyed. Moreover, a fresh start with everything clean and sweet is one of those good points which every grower who studies the well-doing of his plants and his own comfort, I will not say credit, should never allow to slip. If the bottom heat is obtained from pipes lying in chambers, the plunging material can be made warm in a few days; but when large masses of tan or leaves are employed, their proper preparation should be taken in hand some weeks before they are wanted. Meantime, compost, clean crocks, and pots may be prepared, and when the heat of the bed has declined to 85°, weather being favourable, the plants may be potted and plunged forthwith. If the plants have been kept on the dry side and the pots are full of roots, as they should be, water in sufficient quantity to moisten the balls must be given before they are disturbed. Then, although the compost may be dry, and, as a matter of course, warm, the moisture contained in the bed, combined with the gentle dewing overhead and about the walls, will prevent waste until new roots are formed, when a supply of water must be given. As days increase in length and brightness, air on all favourable occasions must be given to prevent the foliage from becoming drawn, and possibly very light shading for a few hours may be needful. From this stage forward the temperature may range about 65° through the night, 75° by day, and 80° to 85° after closing with sun heat. The bottom-heat, as I have before stated, will suit the plants admirably if it can be kept about the last named figures.

Suckers and overpotted plants which it may be thought advisable to reduce or shake free of soil should be left till last, as next to overpotting the most doubtful step that can be taken is too early potting, and on no account should they be disturbed until the new bed is in proper growing condition. The better to prevent the compost from holding

much water in suspension, a small clean pot well crocked should be used, and the firmer in reason the soil is rammed the quicker and safer at this early season will be root action. Plunge the plants with their heads almost touching the glass, avoid shading if possible by shutting off fire-heat early on fine mornings, and prevent waste by keeping the pit close and moist until new growth justifies giving a supply of water. If the space occupied by old stools from which winter fruit has been cut is wanted, they may be shaken out and laid in by the heels for a month or two. An occasional dash with the syringe will aid them in feeding the suckers, which may be detached and potted as they become large enough and suitable quarters can be provided for them. Shy varieties, like the Smooth Cayenne, often force dormant buds into growth; if divested of all their leaves they are lightly buried in soil placed over a strong bottom-heat.

MELONS.

Although early Melon plants have had a severe struggle, a change to milder, but still sunless, weather has brought about an improvement, and where they are growing in well-appointed pits a few bright days may render them worth keeping. Weak, leggy plants are not, however, tempting, neither are they profitable; hence my reason for advising frequent sowings, as it is better to throw away feeble batches and trust to later plants, which not only catch them up, but pass them by and yield fine fruit worth eating. Good Melon seeds are not expensive, as most people raise their own, and the better to start well, a few put into small pots or squares of turf every ten days will always give a supply of plants to fall back upon. But, assuming that the earliest plants have climbed to the trellis and are now making good progress, encourage short-jointed, sturdy growth by the maintenance of top and bottom heats that will favour a chink of air every day to let out vitiated air and keep them clean and healthy by the production of atmospheric moisture in preference to direct syringing. Later on, when the fruit is swelling, copious syringing after the house is closed at a high temperature will be found beneficial not only in keeping the foliage free from red spider, but also in preserving it, as tropical plants never scald in a bath of vapour.

Water, of which the Melon takes copious supplies, may be used pure until the fruit is set; afterwards the addition of liquid from the manure tank, guano water, and occasionally a little soot water will help the plants, always provided they are well furnished with hungry mouths, which can be created by thin top-dressings of fresh loam freely charged with bone-dust. As growth proceeds, be the plants in pots or on hills, every lateral from the base of the stem to the first wire must be pinched out when quite young, but great care must be observed in the preservation of the leaves, as injury to these frequently predisposes them to canker. When two-thirds of the trellis is covered, the pinching of the leading points will throw a flush of laterals, and as these show at the first joint every flower must be fertilised as soon as it opens.

Melons in pits and frames.—Unless plenty of time can be devoted to these, this mode of culture is best left alone until the Blackthorn winter has passed away, but where the first and perhaps the only crop is obtained from manure beds, the preparation of the materials will now be under hand. Many people give preference to brick pits, but unless they are made complete by the addition of a hot-water pipe, I think I should be inclined to go back fifty years or more to the old-fashioned double-boarded McPhail frames permanently fixed upon studs of timber resting in an excavation wide enough to favour the addition of front and back linings. When properly constructed with steam-proof cavities, and the linings receive regular attention, these frames are much drier and warmer than brick pits—no small matter in the cultivation of plants whose greatest enemy is cold, condensed, and stagnant moisture. Although the art of manufacturing a first-class manure bed is nearly

lost, I may observe in passing that this is the foundation of success, for unless good materials are properly prepared and well put together, the seed, as I lately observed on the management of Vine eyes, comes to a dead stand just when power is needed, and the crop is crippled or lost. The next point is compost, which should be sound, heavy rather than light, and good enough to support moderate growth without the aid of solid manure. Old pasture loam corrected with lime rubble in moderate bulk answers best; lighter soils, to which marl has been added, also fosters good growth, and finishes fair fruit, provided it is made very firm and well fed when the Melons are swelling. The last point I shall touch is the selection of varieties and the mode of raising the plants. Free growers and setters like Golden Gem, Golden Perfection, Victory of Bath, Blenheim Orange, and the original Egyptian green flesh are good all-round Melons, and, properly grown, still stand in the front row. But a good start being more than half the battle, a one-light frame placed on a hotbed and well lined should be devoted to the raising of the young plants. If one or, perhaps, two seeds are placed in 4 inch pots, plunged in a bottom heat of 80°, and not more than a foot from the glass, which should be kept clean, sturdy plants will soon be ready for turning out on the hills; but in order to have the fruiting frame in proper condition for them, the making of the nursing-bed should precede the permanent bed by three weeks or a month. If the two seeds grow, the weakest may be pulled out, and the strongest, when three or four leaves have been made, must be pinched to induce side breaks. As these growths will be allowed to extend until they nearly touch the sides of the frame, when they also will be stopped, the soil in the fruiting frame should be ready for the plants by the time the back buds have started. If, on the other hand, it is not ready, a small shift will be necessary, as young Melon plants should never become pot-bound.

CUCUMBERS.

Autumn-sown plants with us have wintered well, and are now producing good fruit. They are growing in very narrow troughs formed by 11-inch boards set on edge and backed up by fermenting leaves, which are renovated whenever the bottom heat descends to 80°. Top dressing, consisting of light rich turf, old lime rubble, and a dash of bone dust, is used lightly as often as the roots reach the surface. Weak liquid is administered freely, but solid manure is never used, as it sours the soil and encourages worms. The air temperature ranges about 65° at night and 70° to 80° by day, and the syringe is used freely when the houses are shut about 1 p.m. for the day. Although spider has been seen it has not been troublesome, and, thanks to Bloxham's fumigator used weekly, our tobacco consumption is very small, and fly never puts in an appearance.

Spring-raised plants.—Where pits have been prepared for these, the soil should be ready for their reception before they become pot-bound, otherwise, like Melons, they must have a shift into larger pots, and as this means two checks where one should suffice, it becomes a question whether plants from later sowings will not beat them in the long run. Cucumber pits, like Pine houses, should be thoroughly cleansed and scalded at least once a year, twice if practicable, and as spring planting generally means a new start, this important matter should never be neglected. If fermenting leaves are at command they should be used freely, as they economise fire-heat and produce genial warmth and moisture, in which all soft-wooded plants luxuriate.

The Oso Berry (*Nuttallia cerasiformis*).—One of the earliest to flower among what are called spring-flowering shrubs is the Californian Oso Berry, which has much the appearance of the common flowering Currant (*Ribes sanguineum*), except that its flowers are white. They are borne in drooping clusters before the leaves are scarcely unfolded. The flower-buds are just bursting now,

and a few sunny days will see the shrub in full bloom. It is a large, round-headed, very twiggy bush, and is well worth growing for the sake of its early bloom. Its usual height is about 5 feet or 6 feet in this country, but in California, its native country, it reaches as much as 15 feet. It grows well on any light soil, and it is always best to plant it in an open, sunny position. It is nearly allied to the *Spiræas*.—W. G.

TREES AND SHRUBS.

W. GOLDRING.

THE BHOTAN PINE.

(*Pinus excelsa*.)

THE Bhotan Pine has become such a favourite ornamental tree of late years, that it is now one of the commonest trees in gardens large and small. The exquisite gracefulness of its growth, its

Full-sized cone and leaves of *Pinus excelsa*.

sheltered. What it does not like is a spot exposed to south-west winds. In such a place the most vigorous young specimens soon show signs of distress; they become weak and straggly in growth, with scarcely any branches on the windward side. For this reason no one would think of planting it on an open hillside sloping to the south.

The Bhotan Pine, coned branch.

As regards soil, I conclude that a deep sandy loam is most suitable for it, though grand trees may be seen growing in dry sandy soil resting on gravel as well as in heavy clays; indeed, it is one of the few Pines that may be planted in absolutely damp places, provided the roots are not perpetually in water. Yet one of the finest trees of it with which I am acquainted is growing by the side of a lake, so near to the water's edge that the roots on one side must be continually submerged. The only thing to fear in planting this Pine in low-lying damp spots is injury from frosts during severe winters, for the growth of trees in such spots is obviously less hardened than that of trees on higher ground. The growth of young trees is most liable to injury, particularly for a season or two after they have been transplanted.

In tree-planting we have not much control over the soil unless we go to the expense of making a suitable soil in places where such does not exist, but usually a choice of situation may be had in every place, and care should be taken to select a sheltered spot for this and other Pines that dislike strong winds. If there is a plantation running east and west, then the place for the Bhotan Pine would be within 50 paces of that plantation, as, though it likes shelter, it dislikes shade, and for that reason it does not do so well at the foot of a northern slope of a hill as in a better aspect. It is my opinion that the proper selection of positions for ornamental trees is of far more importance than soils, and particularly so in the case of Conifers. I have never seen what I should call a good specimen of *Pinus excelsa* on the chalk, but perhaps some of the readers of THE GARDEN may have done so.

The aspect of the Bhotan Pine must be so familiar to all who take the least interest in trees, that a description of it is unnecessary. The only other Pines that closely resemble it when young are the common Weymouth Pine (*P. Strobus*) and the Roumelian Pine (*P. peuce*). When large, say 20 or more feet in height, one can at a glance distinguish them. The Weymouth has shorter leaves, and the leaf-tufts are not so plentiful as in *excelsa*; in fact, the tree is altogether thinner and more inclined to grow erect, while *P. excelsa* always

feathery appearance, and its soft grey colour captivate everyone. It is, without question, a most valuable ornamental tree, and amongst a dozen Pines selected as the best for general culture in any part of the country we should be inclined to place *Pinus excelsa* at the head of the list. It is, moreover, a very accommodating tree; it rarely refuses to grow anywhere if the position is at all

has a tendency to spread. While you see one excelsa with a single erect leader, you may see a dozen others with two, three, or more leaders, and with wide-spreading horizontal limbs. Of *P. peuce* I have not seen large specimens, but plants about 15 feet high are so much like young Bhotan Pines, that one has to look closely for the shorter and more slender leaves. Botanists tell us that *P. peuce* is only a geographical form of *P. excelsa*; but that is questionable, for there is quite as much difference between the two Pines as there is between other so-called species. Grisebach, who closely studied European plants, named it, and, no doubt with good reasons, considered it specifically distinct.

All three Pines mentioned above belong to the five-leaved section of the genus, and all possess the characteristic glaucous tinge in the foliage—a bluish grey tint, in fact—while the smooth bark of the young branches is of an ashen grey colour. The merit of *P. excelsa* consists in its retaining its lower branches well, and these being wide-spreading in isolated specimens, sweep the turf in a most graceful way. It is, therefore, the perfection of an ornamental tree, especially an old tree when laden with its long, drooping cones of a pale russet brown. Adult trees bear cones freely, which form conspicuous objects through the winter. Their seeds are sweet morsels for squirrels, which I saw busily dining off them the other day in the Kew arboretum. They were perched on the topmost limbs, and it was amusing to see how dexterously they nibbled away the scales and extracted the seed: it was astonishing, too, to see how instinctively they knew a seedless cone. I picked up one which they had allowed to fall, and found not a scale touched, and not a seed in it. Some young trees of this Pine begin to cone when only about 10 feet high, but this occurs chiefly where the soil does not induce rapid growth. Its rate of growth is obviously governed by the character of the soil: in the most suitable ground and position young trees grow as much as a foot and even 18 inches annually.

This Pine is one of the characteristic trees of the Himalayan Mountain region, where it is known to travellers as the Weeping Fir. It spreads over a vast area. Gordon, in his "Pinetum," states that it is found principally in Nepal, where it prefers the more open aspects of the mountains, forming in Bhotan extensive and very beautiful woods on the southern slopes. It grows at elevations ranging from 6000 feet to 10,000 feet. In Nepal, Simla, Cashmere, Kumaon, and other localities it grows in company with the Deodar and attains a great height, often over 150 feet in the sheltered valleys. Its timber is excellent, and is one of the staple woods of that region. It is preferred to all other woods for certain work, such as pattern-making, as it works easily, and is free from knots. It is very resinous and fairly durable. This is what the timber is in its native country; what it is grown in this country I have no experience. It does not seem a likely timber tree for this country any more than the Weymouth.

The illustrations herewith given represent a coning branch admirably, but often the cones are solitary or in pairs.

Butcher's Broom.—I never for a moment doubted the hardness of this shrub; indeed I have often found it wild in various parts of England. The point which I wished to make known was this, that in this country, as far as my experience goes, it is a stiff, dark, morose, forbidding-looking plant, huddled and drawn together exactly as if it felt our cold winds, and seldom if ever fruiting (I have only once seen a single berry on it): whereas in hotter climates it is the very opposite—bright, cheerful, spreading, elegant, and covered with exquisite big berries. A plant may be perfectly hardy and yet never come to perfection in a cold climate. Has "W. G." ever seen it fruiting freely in England? Has he ever noticed the utter difference of its habit in Southern Europe, where it is

indeed a delight to feast one's eyes upon?—W. WILKS, *Shirley Vicarage, Croydon.*

KITCHEN GARDEN.

W. WILDSMITH.

NEATNESS IN GARDENS.

IN these times of general depression, which influence horticulture to a great extent, the question of neatness in the kitchen garden may by some be considered out of place, and the labour it involves more profitably employed in the furtherance of a higher standard of cultivation. Those, however, who entertain such an idea would do well to remember that the best cultivation is found in gardens in which some attention is paid to neatness. "Rough and ready" is an old saw that gardeners need not mind, for if a thing is worth doing at all, it is worth doing well. This applies equally to all work about the garden, and satisfaction cannot be expected so long as dirt, weeds, and bad walks meet the gaze. Someone may say, Your logic is all very fine, but I am short-handed, and not having a sufficient number to work the garden as it should be, some portion of it must of necessity be left in the rough, and of course it is the kitchen garden. Two crops on the same ground at the same time is an impossibility, and as weeds will not pay, grow only vegetables, and you will get as much from half your ground as from the two halves with a crop of weeds. The spare half, if no better plan presents itself, can be laid down as pasture till better times admit of its being cultivated. Too large gardens are as difficult to manage satisfactorily as too small ones. Of the two I would prefer the latter, as being more easily worked if foresight be exercised in regard to cropping, while the anxiety concerning appearance would be considerably reduced. It would be difficult to always have everything straight in the kitchen garden, but who expects to see that degree of neatness which is appropriate to the flower garden? At the present time the frost necessitates some extra labour to neutralise the mischief done among the green crops. We are compelled from sanitary motives to remove this decaying matter, and neatness is thus forced upon us. Similar hard knocks might be advantageous to those who act under the false idea that neatness is not an essential to good cultivation.

Gilbert's Jubilee Sprout.—Mr. Gilbert has already enriched our gardens with such a variety of the Brassicaceous race, that it is not surprising he marks the Jubilee year by presenting it with one of his novelties. He has sent us a Sprout which he proposes to call the Jubilee Sprout, and which we have tried both boiled and *sautée*—the way in which the Brussels Sprout is frequently treated abroad—and a very good flavour it has. A benefactor of this kind generally takes his own way, but if we could imprison him and give him work to do, we should turn his attention from vegetables of this race to certain fruits. The production of a really high-flavoured late Apple would be worthy of his attention; whereas the number of the Cabbage race in Western Europe, from Berlin to Oporto, is so large, and the kinds so varied, that we should not lose much if we did not add to the number. We might gain something, perhaps, by studying delicately-flavoured kinds that are little grown in this country as yet; but we every day see evidence of the deplorable fact that, while other countries are sending us, by the thousand barrels, Apples that bring high prices, good late English Apples do not come into the English market.

Veitch's Red Globe Turnip.—Whilst looking after new friends do not let us forget old ones, and this Turnip is one which should have a prominent place in every vegetable garden. It is not an early Turnip, but that does not matter, as we already have several of the strap-leaved sorts which have superseded the Early Dutch. We have the Stones, the Snowballs, and the Six Weeks for summer use, and Red Globe,

which by the way cooks as white as any of the above for winter and spring. Orange Jelly, an excellent winter Turnip, is not perhaps so much grown as it was a few years ago, its colour being against it, but Veitch's Red Globe, equally hardy and very handsome, with its bright band of crimson dying off to pure white near the ground line, is a worthy substitute. I sometimes sow it for summer and autumn use, but my main sowings are made after early Potatoes, and the roots are allowed to stand until the end of February. They are then lifted and stored under a cold north wall, where they keep fresh and tender until the strap-leaved kinds are fit for use.—W. COLEMAN, *Eastnor Castle, Leicestershire.*

CUCUMBERS IN FRAMES.

It is often more economical to grow Cucumbers on a bed of fermenting material in spring and summer than in an artificially heated structure, *etc.*, if the object is to grow them for home use only, and, besides, there are many places where they must either be grown on a manure bed or not at all. The best kind of bed is that composed of nearly equal parts Oak leaves and fresh manure from the stable, thoroughly intermixed and blended. In a bed of such materials properly put together there is not much danger of overheating. Some judgment and experience are required in making up a bed for Cucumbers to go successfully through the season. If the materials are fresh and the manure in excess of the leaves, tread it rather firmly in order to drive out the air and prevent violent fermentation, which has a tendency to carry off all the moisture. A bed 5 feet high at back and 4 feet in front, and 1 foot longer and wider than the frame, will carry the plants through the summer without linings if well put together not earlier than the middle of February. The frames and lights should be washed to clear off any eggs of insects which may have remained from last summer and to remove all dimness from the glass, as it is important that full light should at least, at the beginning, be admitted. As soon as the temperature of the bed has become steady at about 80°, the hills of soil may be placed in the centre of the lights, and when the heat has penetrated through them the plants may be set out. If no provision has been made for

RAISING THE PLANTS in some other structure, the seeds will soon germinate in the frame in question if planted singly in small pots. As soon as the rough leaf appears the young plants should be planted in the hills of soil, which should consist of about two-thirds turfy loam and one-third old manure or leaf-mould. The soil should not be too light, as its tendency in that case is to encourage over-luxuriance rather than early fruitfulness. Cucumbers do not require much soil to grow in, but it is necessary to apply frequent light top-dressings, and some means should be taken to warm the soil before scattering it over the white roots, which are constantly, in the case of healthy plants, pushing their way to the surface. Many growers keep little heaps of fresh soil for the purpose of top-dressing in the corners of the frame at the beginning of the season. Later on, spreading it out in the sunshine will warm it sufficiently. The water used should have its temperature raised to that of the frame, either by adding hot water or by setting the vessel containing it in the frame some time before using it. Liquid manure should be given freely after bearing begins.

STOPPING THE SHOOTS.—Rub out the leading bud as soon as the plants arrive at what is termed the rough leaf stage. When the leading bud has been pinched out other buds start away below it, and these shoots soon begin to spread over the frame on all sides. When some progress has been made the terminal buds are pinched out, and very soon male blossoms and fruits make their appearance. The shoots should be pegged down as they advance in growth, and sprinklings of compost should be given at least weekly. These light, weekly dressings are very encouraging to the plants, and tend to keep the atmosphere of the

frame sweet and buoyant. The regulation of the growth may for some time at least be done with the finger and thumb, pinching each shoot one leaf beyond the fruit; also pinch out or stop any shoots not required for filling the frame. Ventilating and shading are two operations closely linked together in Cucumber culture; only enough shade should be used to prevent scorching, and just as much ventilation should be given as will ensure robust growth and no more. If a piece of scrim or canvas be hung over the opening for ventilation, the atmosphere in the frame may be changed without creating cold currents. Warm coverings will be required at night till the summer is well advanced.

INSECTS AND DISEASES.—Greenfly and red spider are always ready to take advantage of conditions favourable to their attacks. Robust, hardened growth is the best preventive of these, and also of mildew, which is sometimes troublesome if the least stagnation occurs in the growth of the plants or in the atmospheric condition. Very often the Cucumber frame is crowded with pots of cuttings, pans of seedlings, &c., and though within reasonable limits the genial temperature of the Cucumber frame may be taken advantage of for forwarding many things for which there is a demand in spring, much watchfulness is required to keep the atmosphere fresh, sweet, and buoyant. Sulphur is the best remedy for mildew where it does occur, and it should be applied the moment the first white spot appears. At the same time the cause should be removed, the frame should be cleared of most of the pots and pans which it contains, and a top-dressing of fresh compost should be applied. Greenfly can be kept out by an occasional moderate fumigation of tobacco, and red spider by the application of moisture, accompanied by a close atmosphere for a time. But the most serious disease which attacks Cucumbers is a kind of gangrene or ulceration which attacks the fruit, and is first made known by the exudation of gum from its sides, which renders it unfit for use. There is at present no remedy for this disease. If taken in hand early, the temperature increased, and more moisture than usual thrown into the atmosphere, it is sometimes possible to drive it out, but the result is always uncertain; and in a general way it is safer and better practice to make a clearance of everything and to burn all that can be done in order to destroy any germs which the soil may contain. Well limewash the house or frame, clean the paint and glass, and begin afresh with new soil and fresh plants from another source.

VARIETIES—The Telegraph, Tender and True, Cardiff Castle, and Model are all good varieties for frame or house culture. E. HOBDAY.

SEED POTATOES.

MR. MUIR'S strictures on the samples of seed Potatoes sometimes obtained from seedsmen may, in his experience, be justified, but I think the picture is rather overdrawn. In dealing with Potatoes intended for seed, and especially with those of the more expensive sorts, lift them on dry days and allow the tubers to lie on the ground for a few hours to dry; pick out all the larger samples first, then the seed sample, and the very best tubers for seed are the middlings; carry these into a yard or enclosed space and where there is a hard floor, lay them out there for a whole day in the sun and wind; then carefully go over and select again, rejecting all ungainly, small, and diseased tubers, and then place them in a shed on shelves, or in greater bulk on floors, or perhaps in bins or large boxes, where the tubers can obtain ample air and, if possible, light. Now, it is not possible for anyone to give greater care and attention to the tubers than this, or to afford them more suitable treatment to endure the winter's storing. As a result, I can say that not a bushel of tubers out of tons, even of the earliest sorts, has yet pushed a shoot, because with all this exposure there has been an average low temperature, which is beneficial to the tubers. When we have very soft, mild winters no power can prevent growth; but this is certain, that with careful selection, ample harden-

ing, and air during the winter after storing, any harm arising from early or premature starting is very much minimised. I must object to the statement that Potato seed tubers generally are treated badly. Such a stricture may have had fitting application twenty years ago, but it does not apply now. Then it is most improper to assert that Potatoes rejected for cooking should never be used for seed. In my experience of seed Potatoes—a very extensive one—I have ever found that preference is shown to the size which we invariably regard as just below ware or cooking tubers. Good sound hard tubers of about two ounces in weight are the very perfection of seed tubers, far before others double the size, which need cutting ere planting, or if planted whole are so much food wasted. Tubers of the weight named, however (2 ozs.), are, of course, held to be too small for cooking. As I have never illustrated a Potato I am not amenable to the charge that the seed tubers bear no comparison to the pictured tuber, and it must be admitted that whilst in shape fair enough, the coloured illustrations so often seen of Potatoes in seed lists are absurd enough. Still, these are but assumed to represent not seed tubers, but the best selected samples, as no one illustrates the worst of anything. After all, I think that Peas and some other things are much more unfairly illustrated than ever Potatoes are. However, I think if gardeners or others wish to obtain seed Potatoes from any respectable seed firm, they will have little cause for complaint. The Potato seems to be a black mark with some writers. I hold, none the less, that there is to be obtained in the trade seed Potatoes equal in quality to that found in any other article in the seedsmen's lists. A. D.

KITCHEN GARDEN NOTES.

VEGETABLE FORCING.—In order that no check to growth may take place, it is important that the linings round frames containing Potatoes should be renewed at least once a fortnight during very cold weather, and once in three weeks as the weather becomes milder, and fresh soil should be added as soon as any roots are seen on the surface. We usually sow Radishes thinly between the rows, and where this has been done the soil will have to be stacked in ridges in the same way as in outdoor earthings; if needs be, as soon as the Radishes are pulled, additional soil may be put between the rows. Having made up other beds on which to plant Potatoes, the framework—long, thin planks to hold the soil together—is now being put into position, and stout Hazel rods hooped over on which will rest the covering to protect them from frost. Light soil of any description, from 12 inches to 15 inches in depth, will grow good Potatoes, and as soon as the heat has subsided to a temperature of 70° they may be put in with safety. Between the rows of the Potatoes we shall sow Coleworts, which will be fit for transference to the open air before the Potatoes require additional soil. Carrots do remarkably well in these makeshift frames, and there being virtually no labour needed other than covering them over in severe weather, they should be grown in quantity this season, as there is sure to be a dearth of good vegetables this spring. French Beans I have always found to do best in pots, but they take up so much room at a time when every placed is crammed with bedding and other plants forced for supplying cut flowers that they are more conveniently grown in pits after this time. They do not require much bottom heat; 60° will do, but 65° would be better. Leaves are about the best heating medium for them, and if not too wet a bulk 4 feet in depth gives off that amount of heat. Equal parts of loam and roughish leaf-mould make a good compost for them, and a sufficient depth is about 8 inches, as the plants root down into the leaves, much to the advantage of the crop. We sow very thinly in drills a foot apart, and thin out the plants in the row to 6 inches asunder as soon as the first leaf is well formed; there is then no danger of injuring the roots of the plants that are to remain, which would be the case if they were left to get matted together. Keep the soil nicely moist

through—not sodden—and syringe daily when the pit is being closed for the night. The temperature should never be lower than 60° by night, and from 65° to 75° by day, according as the weather is cold or warm. Any of the varieties will force, and there is really very little difference in earliness between Sion House, Fulmer's Forcing, O-born's, and Canadian Wonder; the last named I prefer because it never fails to crop heavily and is of such robust growth as to disregard a little rough treatment. Mustard, Cress, Mint, Tarragon, and Chervil are conveniently grown in corners of the French Bean and Potato frames in small boxes or pots, according to the quantity of each that is required. Attention to put in the several sorts in time to succeed the crops exhausted can only be done by some such method as setting apart a certain day in each week to, as it were, take stock of such matters, and act accordingly.

PARSLEY.—The late severe wintery weather has made sad havoc with this, both under the protection of a frame and in the open border: consequently to avoid a failure as regards the supply we have lifted a lot of the strongest roots and planted them in boxes and put them in ainery that is being forced, and a sowing will as soon as possible be made at the foot of a south wall, but the general sowing will be deferred till March. Being hard up for a suitable place in which to continue the supply of forced Asparagus, we lit on what is likely to turn out to be an excellent plan. We have a large stack of leaves stored for Pine growing; on the top of this stack we levelled the desired space, put on a thin layer of soil, then the plants, covered the whole with 6 inches of light soil, and gave a good watering. During the late frost we covered up the bed with mats, and now we shall erect a trellis on which to lay the mats whenever the weather is cold. The bottom-heat thermometer pushed well into the leaves registers 86°, so that the heat is not likely to get excessive, seeing that the plants are quite on the top of the stack. All our Seakale is now planted in large pots, and a constant supply is kept up by putting a couple or three pots into warmth every week. The roots of all that have been forced are saved, as many of them will do to re-plant, and meanwhile all are heeled in under the shelter of a wall.

LETTICES.—We have pricked out in cold frames the plants raised in heat, and they will be planted on a south border as soon as they have acquired sufficient strength to withstand the cold easterly winds so prevalent in spring-time. After this time all the sowings of Lettuces will be made on the ground where the plants are to mature, this being the only method by which we can secure fine crisp heads throughout the summer on our light soil. We shall make our first sowing at once on a narrow, well-sheltered border, in rows a foot apart, and thin out the plants to 9 inches asunder in the row. Soot, wood-ashes, and Beeson's manure are all excellent fertilisers sprinkled between the rows a week or so after the thinning out is done. Sowing "little and often" is the surest way of maintaining a continuous supply. The Cos varieties are generally the most prized, and rightly so, for they have the double advantage of being less liable to seed and of higher quality than the Cabbage varieties, Paris White and Paris Green Cos, and the many closely allied types of these are all excellent.

SHALLOTS AND GARLIC.—Had the weather been favourable, these would have been planted ere this. The ground—a deep, highly manured loam—is quite ready for them. For the Shallots we allow a space of a foot by 9 inches, and for the Garlic a foot each way; these distances we find to be none too much, considering the clusters of bulbs which they make in highly tilled ground. We plant deeper than is generally done, the sets being completely buried and made extra firm with the view of preventing upheaval by frost. This was the only reason we had to favour deep planting when it was first adopted, but the success has been such, that we should plant just as deep, even if we could feel sure that there would be no frost, as I am satisfied that both

clusters and single bulbs are larger, because not so liable to be affected by drought. Thus growth is continuous, and as both naturally mature early, there is no risk of bad keeping owing to lack of ripeness. Sound and large sets should be selected, not that small sets always give small produce, though for the most part they do; it is therefore wisdom to strive to avoid any such mishap by selecting the most perfect seed.

LEEKS—We southerners are not so enthusiastic as regards the cultivation of Leeks as our northern brethren, and the reason is we have but little demand for them. If we had they would be forthcoming in abundance, as there is no more skill necessary in order to grow a good crop of Leeks than one of Celery or Onions. We always grow a few, as they may possibly be asked for about twice during the season, but for all that we try to grow them well, and now is the time to sow them. Good soil and an open exposure will suit them; sow rather thickly in drills, and as soon as large enough to handle transplant them to their permanent position, which should be a sunny exposure, and the soil deep and well enriched with farmyard manure. Draw deep drills 15 inches apart and plant with a dibber, allowing each plant at least 9 inches of space. Should the weather be dry at time of planting, give a good soaking of water, and repeat the same if needs be till the roots have got well established. As the plants progress in growth fill in the trench, and towards the end of the growing season, should the length of the plants warrant it, earthing up, the same as is done in the case of Cabbages, will assist the blanching. This constitutes the whole of our practice in Leek growing, but were this vegetable demanded of us in the highest perfection we should give it still more liberal treatment, and grow it in much the same way as Celery and Cardoons are grown.

GENERAL WORK consists in trenching ground lately cropped with Parsnips, and which will be required for our main crops of Peas; therefore all the manure that can be afforded is being worked into it. The frost has hindered the sowing of Parsnips, Onions, and a second lot of Peas and Broad Beans, but now that a change to milder weather has set in, we are preparing for sowing by roughly raking down the soil, an operation that has to be repeated on two consecutive days in order to get it sufficiently fine for the drawing of seed drills. Ground not over-rich may have a surface-dressing of artificial manure spread over it before raking is done, as by that means the manure gets well worked into the soil, and the drilling gives it another fillip in the same direction. For Turnips we prefer this way of manuring to all others. Soot is the main ingredient used, and even in the driest season this appears to answer, as we seldom have to complain of injury from fly. Our first-sown Peas in the open air are just breaking through the soil, and unless at once made distasteful to sparrows and tomits, the points will soon be nibbled out. Soot and lime deter them, but the dose must be repeated after each heavy rain. If the rows can be staked at once and made extra thick at bottom by the use of Evergreen spray, this balks the birds so much, that unless hard pressed for food they avoid them. Another sowing of Peas and also of Broad Beans will be made during the week, and just a small patch of Early Munich Turnip, a variety that differs from other kinds quite as much in its non-liability to run to seed by reason of early sowing as it does in being ready for use in an exceptionally short time. It is not a good summer Turnip, for directly hot weather sets in it gets so bitter as to be quite unfit for use. All through the spring the quality is passable, but its principal claim to notice is its earliness.

W. W.

Odontoglossum gloriosum.—The finest form of this species which has come under our notice is now flowering in the select collection of Orchids belonging to Mr. Jacob, at Stamford Hill. *O. gloriosum* of Bateman is now, however, merged into *odoratum* of Lindley, and the plant in question certainly much resembles that known as *O. odoratum* Lecanum. The panicle is much-branched and many-flowered; in the blossoms, which are large and richly coloured, the lip

is profusely blotched with reddish brown in front, and in addition to the beauty of their markings, the flowers yield a delicate perfume resembling that of Whitethorn.

ORCHIDS.

W. H. GOWER.

INTERMEDIATE HOUSE ONCIDIUMS.

THE prevailing colour of the flowers of the different species belonging to this somewhat large genus is yellow, although there are some notable exceptions, one of which is *O. Jonesianum*, figured the other day in THE GARDEN. Many of the earlier introduced species were small-flowered, and although a few years back these were highly prized, they do not now-a-days find much favour with Orchid growers. Nor is this to be wondered at, seeing that numbers of new large-flowered kinds have been discovered and introduced in a living state in quantity. Those commencing the cultivation of Orchids should select kinds that will maintain a good display of bloom

Oncidium curtum (showing habit of growth).

throughout the season. In some instances even a houseful of bloom, consisting of one species and its varieties, is a grand sight, an example of which we had recently in Mr. Sander's nursery, where many hundreds of blooms of *Cattleya Trianae* were to be seen, but such a display only lasts about two months. A succession must, therefore, be secured, and, as in the case of the *Cattleyas* given in THE GARDEN (p. 175), we have described a dozen *Oncidiums*, which will thrive under similar conditions of temperature and form good companions for them. *O. Cavendishianum*, although an old kind, cannot well be dispensed with, as it is one of the earliest of intermediate house species to produce its flowers, which usually appear in January and February, and last six weeks in perfection. It is a massive-growing plant, and for that reason should be kept in a pot. It has few or no pseudo-bulbs—its leaves, which are erect, very thick

and fleshy, are keeled at the back and vivid green. It produces its blooms in great branching panicles, on which the single flowers measure an inch or more across. The sepals and petals are dull yellow, spotted with red, and the lip, which is flat, is bright yellow.

Flower of *Oncidium curtum* (full size).

O. concolor, which is a native of the Organ Mountains, should be grown in a suspended basket; not only does it succeed best thus placed, but its racemes being pendulous display their charms to the greatest advantage in that way. The pseudo-bulbs (which are ovate and furrowed), and also the short, strap-shaped leaves, are bright green. The flowers, which appear in March and April, are large and wholly bright clear yellow, with the exception of the two raised ridges at the base of the lip, which in some varieties are red, and in others orange. *O. sarcodes* is another Brazilian plant, the pseudo-bulbs of which are erect, almost cylindrical, and dark green. These bear a pair of short, broadly lance-shaped leaves of a deep shining olive-green. The panicle, which is large, is much branched and many-flowered; the sepals and petals are yellow, and more or less profusely blotched and streaked with reddish brown, and the lip, which is flat, is also clear bright yellow, dotted towards the base with red. The flowers of this species usually open during April, and before those of *O. concolor* are over. *O. Marshallianum*, a Brazilian *Oncidium*, is of the showiest belonging to the genus. It blooms during April and May. Its panicles, which are erect and branched, bear many flowers, and the individual blooms measure 3 inches across. The sepals are yellow, transversely banded with chestnut, and the petals, which are of the same colour, are not banded, but blotched along the centre; the lip, which is large, flat, and bilobed in front, is brilliant clear yellow, with a saddle-shaped blotch of chestnut at the constricted base.

O. Marshallianum is often in perfection in May, and *O. ampliatum majus* is a fit companion for it; the large, somewhat flat pseudo-bulbs of this variety are apple-green freckled with dotted lines of red. The leaves, which are flat and broad, are pale green; this, being a massive, heavy-looking plant, should be kept in a pot. The panicle, which is some 3 ft. or more in height, is much branched, and bears a profusion of flowers of the clearest and brightest yellow in front, but white behind. This variety comes from Costa Rica. *O. crispum*, which is a native of Brazil, and thrives best on a block, comes into flower in May and June. It is peculiar on account of its having rough, almost brown furrowed pseudo-bulbs, which bear a pair of broadly lanceolate, coriaceous, dark green leaves. The panicle, which is branched, bears often-times half a hundred flowers, each of which measures between 2 inches and 3 inches across. The colour varies much, but in the typical form the whole flower is rich brown, with the exception of the base and crest of the lip, which are orange-yellow dotted with red, the edges of the lip as well as those of the sepals and petals being beautifully waved and crisped. The Butterfly *Oncidium* (*O. Papilio majus*) should be grown upon a block of wood or in a suspended basket. Its pseudo-bulbs are compressed and rough, and the leaves are also rough and solitary, deep green above and conspicuously marbled with reddish brown tessellations; beneath they are reddish brown, profusely dotted with emerald-green; these markings vary

much in intensity in different plants. The scape, which is slender, and from 2 feet to 3 feet in length, is terminated by a sheath, from which numerous flowers issue in succession; it is seldom, however, that more than a single flower is open at any one time, but if the plant is large, many scapes will be produced, each of which will bear a flower, which from their peculiar formation have a striking resemblance to butterflies on the wing. The old flower-scapes should be retained from year to year, as they will make lateral branches, and thus add their quota to the general effect. Each flower measures between 3 inches and 4 inches across the petals, and more than 6 inches from the base of the lip to the tip of the antenna-like sepals; the three sepals, which are erect, are long and narrow, and dull purple, with a few narrow, scattered bands of yellow; the petals are broad, deflexed, tapering to a point, chestnut-red, and irregularly and transversely streaked with orange-yellow; the lip, which is flat, is clawed, nearly circular, and orange-yellow in the centre, margined with a broad border of chestnut red; the structure of the side lobes and that of the crest of the lip, together with the column, materially support the supposed resemblance which this flower bears to a butterfly. *O. Kramerianum* is another Butterfly Oncidium, the flowers of which, however, are different from those of the last; in this case the petals are deflexed, pale yellow, profusely spotted and dotted with reddish brown, and very wavy at the edges; the lip, with the exception of the crisp margin, is large and flat, broadly fiddle-shaped, pale yellow, and bordered with brown spots; the peculiar knotted flower scape is a marked feature in this species; both this and *O. Papiho* continue to flower for many weeks at a time.

O. Lanceanum, a grand vanilla-scented species, is somewhat difficult to keep in good health; this difficulty has, however, to a great extent been overcome by Orchid growers during these last few years. It requires plenty of air, and its roots should be kept in confinement; therefore it thrives best in an open suspended basket, well exposed to light. It is destitute of pseudo-bulbs, and its large, fleshy leaves, light green profusely dotted with purple, resemble those of *O. Cavendishianum*. The flower-scape is erect, and the individual flowers measure nearly 2 inches across; in the typical form the sepals and petals are greenish yellow spotted with reddish purple, and the lip, which is broad and flat, is rich violet, the middle lobe being deep purplish violet. In the variety *Lawrenceanum* the expanded front lobe of the lip is pure white. *O. Gardneri* belongs to the crispum section. It comes into bloom about July and its flowers, which are sweet-scented, are very long-lived. The panicle, which is erect, is much branched and many-flowered; the sepals and petals are bright brown, bordered with pale yellow and crisped on the edges; the lip, which is very broad and rich golden yellow, has a spotted marginal border of chestnut-brown. *O. Jonesianum*, of which a coloured illustration was given lately in THE GARDEN, is a new, distinct, and beautiful species which should be grown upon a block and suspended head downwards; its deep green leaves are long and Rush-like, whilst the panicle of bloom (when the plant is strong) becomes branched and many-flowered. The sepals and petals are greenish yellow, blotched and spotted with brown or crimson. In some forms the lip is pure white in front, with a yellow ear-like lobe dotted with crimson on each side at the base. In others the richly-coloured spots are irregularly spread over the middle lobe. *O. Rogersi* is a variety of *O. varicosum*, itself a very fine, free-flowering Orchid, and if the best variety cannot be obtained, the typical form should be substituted. The panicle is densely branched and the flowers numerous, often over a hundred on a panicle. The sepals and petals are very small, the lip large, flat, deeply lobed in front, and of a uniform rich deep yellow. *O. curtum* is nearly related to *O. crispum*, and extremely floriferous, as will readily be seen by a reference to the accompanying illustration. The sepals and petals are rich clear yellow, blotched and dotted with bright brown. The lip is bright golden yellow bordered with cinnamon-brown, and flushed with purple on the disc. These Oncidiums require very similar treatment to that recommended on p. 176 for Cattleyas, but their roots like rather more water

than Cattleyas during the growing season, and they will bear a little more resting during the winter. Those kinds recommended for block or basket culture should be carefully watched during the resting season in order to avoid excessive drought.

Phaius grandifolius.—Several large pots of this handsome Orchid in one of the houses at Penrhyn are just now a sight, and a most enjoyable one too, for rarely indeed have I seen this winter-flowering plant in better condition. Not one, but most of the plants have as many as ten flower-stems of nearly 5 feet in height, and with from fifteen to a score of flowers on each. The big, bright green, Palm-like leaves, combined with the luxuriance of the flower-spikes, clearly point out that Mr. Speed knows well how to manage this gigantic Orchid, and which he values highly for cutting purposes during the winter months.—W.

Odontoglossum hebraicum.—This rare and beautiful plant is said to be a form of *O. odoratum*, but if so, it differs widely from the type. Its appearance impresses one with the idea that it is a hybrid, but between what parents it is difficult to assert. It produces dense panicles of large, showy flowers, the sepals and petals of which are yellow, streaked and profusely spotted with chestnut-red, whilst the lip, which is spear-shaped, is yellow, marked with radiating reddish crimson lines at the base, and blotched in front with velvety maroon. We recently saw two very distinct forms of this plant flowering with Mr. Jacomb at Stamford Hill.

Cattleya Trianae Ernesti.—This is perhaps the finest form of this variable Cattleya that has yet bloomed in this country. The flowers are very large, sepals and petals broad, lilac-mauve tipped with magenta, slightly flaked down the centre of the petal; lip large, the front lobe rich crimson-lake, deeper at the base, where it is met by rich deep orange which fills the throat. We recently noted this fine form with Mr. R. J. Measures in his garden at Cambridge Lodge, Camberwell, where also blooming at the same time were several other remarkable kinds, such as the true pure white form called *alba*, and the variety *Symeana*, which has bluish sepals and petals and a very fine lip, crimson in front and deep orange in the throat; also *Amesiana*, likewise a rich and rare form.

SHORT NOTES.—ORCHIDS.

Odontoglossum crispum Stevensi.—One of the finest of the spotted forms is now in flower in Mr. Pollett's collection. This variety opens with a yellow ground, subsequently becoming paler. It is blotched and spotted with reddish brown.—J. D.

Dendrobium Wardianum. A variety of this is now flowering in the nurseries of Messrs. Hooper, at Twickenham, different from the typical variety, in which the petals and sepals are tipped with magenta. On the plant in question, however, they are pure white and very pretty.

Dendrobium endocharis.—This variety, a cross between *Dendrobium heterocarpum* and *japonicum*, is worthy of note, both on account of its perfume and its fine shades of colour. It has a remarkably long labellum with purple throat, the petals and sepals being a beautiful ivory-white.

Brassavola glauca.—This very desirable Mexican Orchid is now in fine condition in the Cattleya house in Messrs. Veitch's nurseries. The petals and sepals are greenish white, and the labellum white with a slight tinge of pink on the upper part. It will last for a week or two in good condition.

Masdevallias.—I have sent a flower of *Masdevallia Veitchi grandiflora*, also two flowers of different varieties of *Masdevallia amabilis*, for your opinion. I have *Cymbidium Lowianum* with twenty-six flowers on one spike, and twenty-two on another. Is that about the average number for it to bear?—J. OSBORNE, *Wilton House, Southampton.*

* * * The flower of *M. Veitchi* is a very fine one, measuring upwards of 6 inches across. In one variety of *M. amabilis* the flowers are very dark, the lower concave sepals being deep crimson-scarlet. Your plants of *Cymbidium Lowianum* must be strong to produce the quantity of flowers you name.—Ed.

Odontoglossums.—I potted some imported bulbs of *Odontoglossums* some few months back, and placed them in a greenhouse where they soon began to grow. I then placed them in a small stove in which the heat varied from 50° to 70°, and kept them rather damp. Some have since done badly, and the bulbs have withered and died. Have I given too

much water, or too much heat? The pots were plunged in *Cocca* fibre. I have now replaced them in the greenhouse in which the temperature is from 40° to 50°, and plunged them in *Cocca* fibre. My Cattleya in the stove are growing, but not so well as I should like. Perhaps the house is too dry.—A. B.

A YEAR'S CROPS FROM COLD PITS.

THE purposes for which cold pits and frames may be used are so many, that it is doubtful whether there are any other structures that yield the same return as these when their cost is taken into account. To-day I was occupied in filling a four-light brick pit with Strawberry plants for the production of a crop that will fill up the gap between those forced in pots and those in the open; as a matter of course, the plants have been well prepared. The earliest runners were taken and planted in a rich piece of ground early last July. During autumn all runners which they made were taken off and weeds kept down. To-day they have been lifted with grand balls of roots and planted in a bed of soil in the pit, 15 inches apart each way. When the planting was finished they received a good soaking of water, and, with the exception of giving them plenty of air, an occasional watering, and cutting off the runners as they appear, they will involve no further trouble, unless it be placing a mat on each light when frosty. We shall thus get a crop of fruit equal in size and flavour to the best grown in the open ground. In the meantime a sufficient number of plants of Tomatoes will be got ready. The variety we prefer is Hathaway's Excelsior. The lights being 4 feet wide, two plants will be provided for each. The Tomatoes, well established in 7-inch pots, will then succeed the Strawberries. We have some galvanised wire hurdles that just fit the interior of the pit; these are fixed 1 foot from the glass and to them the Tomatoes are trained. One plant is put in at the back and the other in the front, in the same soil in which the Strawberries grew. Towards the end of the season we generally let one plant monopolise the space of one light, and cut most, if not all, the back ones out. If I had not the wire hurdles I should stretch some wires along, or make temporary frames with builders' laths on which to train the growths. When the Tomatoes are over the wires are taken out, the soil stirred up, and Endive to be preserved for use as winter salad is put in. It will thus be seen that this pit is never unoccupied, and that it affords protection for three important crops in one year. But no one need be confined to these crops only. The routine may be varied by substituting Potatoes or an early crop of Radishes instead of the Strawberries, or some roots of Asparagus may be lifted and brought on in advance of the outdoor crop. Seakale may also be brought on in the same way. The frames may also be used for the protection of bedding plants, and then leave time enough to get a crop of late Cucumbers. French Beans may be substituted for Strawberries if not planted until the end of March. This will prove a very valuable crop, and will prolong the season of that useful vegetable fully three weeks. In the case of movable frames they may be utilised to protect Vegetable Marrows until the end of June, which will bring on the crop much earlier.

In autumn these structures may be filled with Violets, which will flower during winter and spring. At the end of May the Violets may be taken out, and, with a little fermenting material to furnish a gentle bottom-heat, a crop of Melons may be obtained in August. Cold pits may also during summer be used for at least three months in sheltering greenhouse and stove plants, which do better in a properly managed pit in hot weather than in houses. This is particularly the case with young stock of such plants as *Ericas*, *Azaleas*, *Linum trigynum*, and *Poinsettias*. The cool bottom on which they generally have to stand prevents the soil drying up so quickly as it does in houses. During the autumn and early winter months such plants as *Cinerarias* and herbaceous *Calceolarias* do much better in frames than in heated structures. In many cases *Cyclamens* are better planted out in a bed of soil in them than when kept growing in pots. In the early spring months such annuals as *Asters*, *Ten-week Stocks*, and *Zinnias* may be better raised in these structures than in houses, and the same frames may be used during the winter for the protec-

tion of bedding Calceolarias, &c. It will thus be seen that there is hardly any limit to the uses to which they can be appropriated, and where there is a large demand for a variety of subjects one can hardly have too many of them. Every small garden ought to be provided with a brick pit at least 20 feet long and 6 feet wide, and two or three portable frames. J. C. C.

MARKET GARDEN NOTES.

THE late drying winds have left the soil in good order for cropping, and all hands are now busy getting in the earliest crops. The soil, being light and well drained, is naturally warm, and seeds may therefore safely be sown earlier than in cold, stiff soils; moreover, the seedlings get deeper rooted before droughts can affect them. The crops that come in for first sowing are—

PEAS.—Of these the earliest kinds are now mostly sown, and some of the second earlies will get attention at once; for when once picking begins market-growers soon clear the land so as to get in other crops, as after two or three pickings they do not pay to go over, and are cleared off and given to the pigs or sheep. In this part of the country Kentish Invicta, Ringleader, and William I. are popular early kinds; and Harrison's Glory, Pride of the Market, Veitch's Perfection, Main Crop, King of Marrows, and No Plus Ultra, late kinds.

BROAD BEANS are sown as early as the soil will permit getting them in. Only two or three sowings of these are made, as a rule, as they are not profitable after other Beans come in. The Longpod, Johnstone's Wonderful, and Windsor are the sorts sown, in the order named.

RADISHES are sown largely as early crops on warm borders. They are generally sown broadcast, in beds about 1 foot wide, and covered with straw, which is removed during the day when fine and returned at night. The long red sorts are the best for early sowing, and the white-tipped French Breakfast is also much in request. The Turnip-rooted kinds are sown next month in large quantities.

ONIONS.—These are being transplanted from autumn-sown beds and put out on very rich soil that has been deeply cultivated and well enriched with manure. The Giant Rocca and the Tripoli varieties are the sorts used for transplanting, and the white Spanish for pulling while green for salads. The soil is being got ready for spring sowing, as a good seed-bed is of great importance for Onions: liberal manuring, deep cultivation, and getting the seed in when the surface is dry are the points on which market growers rely for good crops. James's Keeping and Bedfordshire Champion are the favourites, as they keep well until the spring, when there are few foreign Onions in the market.

CARROTS of the Early Horn type are being sown both in frames and on warm borders; a light, friable, sandy soil to produce bright, clean roots without much fresh manure is the one selected for this crop. They are pulled as soon as they are of sufficient size. The Early Scarlet Nantes is now in great favour, rivalling the old French Horn, so long used for early work.

PARSNIPS are sown already by many, while others are getting the land ready. This crop delights in stiffer land than Carrots. Deep cultivation is also necessary to produce long, straight roots, but no fresh manure is applied, as it causes the roots to become forked. The Hollow Crown and Student are the varieties grown.

POTATOES of the early kidney kinds are planted out in frames and on warm borders, and a quantity laid out in boxes to sprout ready for planting. The earliest main crop here is of the American Rose and Beauty of Hebron types, as they fill the measure sooner than the kidney varieties. The planting of these will be pushed on directly milder weather prevails.

CAULIFLOWERS that have been wintered under handlights are being thinned out and put under cloches or any other slight protection, and are usually grown close to the homestead, where shelter can be given them.

CABBAGES that have stood during winter in the seed bed are now being transplanted into rows rather thickly, to follow those put out in autumn, and seed is being sown as they are one of the all-year-round crops.

LETTUCES are being planted out in quantity; they are of the Brown Cos and Cabbage varieties, and boxes of seed are sown under glass for succession.

Frames and hotbeds are now being put in order for the season; seeds of Cucumbers, Tomatoes, and other crops that it is desirable to get as early as possible are already sown. Tomatoes are especially benefited by early sowing, as our summers are too short for them unless every day is utilised. They appear to be more in demand every year. I find many are reducing the space devoted to Cucumbers and increasing that for Tomatoes; a good selection of the old Smooth Red is the favourite with market growers, and with Cucumbers Telegraph is still the one selected.

Hardy fruits are being pruned, manured, and cleaned; the prospect of a good fruit crop could not be better, as the severe weather has kept the buds dormant, and the season last year was very favourable for the growth of good clean wood; in fact, I never remember to have seen finer foliage on fruit trees of all kinds than last year, and if we get a favourable spring I anticipate a heavy crop. Bush fruits that are now being pruned have been badly injured by birds taking the buds. In this locality the sparrows are the chief enemies, and they are so daring that nothing but close netting up or the gun will stop them.

Strawberry beds are being cleared of weeds, runners, &c., and a mulching of manure applied. Newly planted beds that have had the soil loosened by frost are being trodden down firmly round the plants. Cob Nuts and Filberts are now being pruned. They are cut in very closely, only the fruitful spray being left; a dressing of old rags or town refuse suits them well. The high price of English Apples has led growers to pay more attention to our long-neglected and starved orchard trees. J. GROOM.

Gosport.

NOTES OF THE WEEK.

A red striped Snowdrop. I have a small patch of Snowdrops like those sent, *i.e.* striped with red. Can you give any idea how that has occurred?—E. PITCHER, *Cringletree, near Norwich.*

The petals are striped inside with reddish pink. These lines are fainter on the outside, but have a tendency to flush the whole flower with pink. It seems a very interesting variation, but probably no variation on the common Snowdrop can ever be made with advantage.—ED.

An exhibition of Apples and Pears will be held at Chester on March 3, 4, and 5, with the view of ascertaining the best late varieties grown in the district. A conference will be held in connection with the show, at which papers will be read and discussed.

Anthurium Andreanum.—I send you a spathe of this Anthurium, which has been in full beauty since the beginning of November last. It is one of the best of the Anthuriums, as if kept steadily moving it will continue to throw up its brilliant scarlet spathes during the greater part of the year.—W. JOPP, *Torquay, Eastbourne.*

* * A magnificent spathe, 6 inches in length and 5 inches in width, the spadix being 4 inches in length.—ED.

Destroyers of wild plants.—I observe that once again the wanton destruction of native flowers has been the subject of condemnation, and not too soon. Each succeeding year shows how rapidly even the once famous Devonshire lanes are losing their beauty, and not only so, but the same idlers who plunder the lanes and fields also steal from gardens, choosing by preference such plants as Snowdrops and Lent Lilies, which might possibly be wild. These flowers are hawked about the streets and offered for sale at houses in Torquay, Totnes, and other towns, and purchasers are only too readily found for such goods. There is but one way to remedy this evil, and that is by a general agreement to refuse to buy their wares. The sacrifice is not so very great, considering the profusion of flowers (of the same kind if preferred) which may be bought clean and fresh from respectable nurseries; and surely, independently of this resource, no honest person would knowingly abet theft. The Lent Lily robberies from orchards and gardens have just begun; but as regards Snowdrops, only last week the raid was extensively carried out, not only from the pleasure-grounds of the wealthy, but from the gardens of the cottagers; and let those who so thoughtlessly buy the stolen goods remember

that their flowers are a delight to cottagers and a legitimate profit, too, if they choose to part with them.—T. H. ARCHER-HIND, *South Devon.*

Tecophylæa cyano-crocus Leichtlini.—This, the loveliest of all the spring blue flowers, is too seldom seen. It is now in perfection here. I find that tiny offsets not bigger than a Pea will often give one bloom, and the larger bulbs throw up three and sometimes four. Mr. Wilson, I believe, has it outdoors at Weybridge, but I have not yet so tried it, as until it is really plentiful it is far too precious to risk outside. I do not, however, give it any heat, but simply a cold frame to grow in and a cold house to bloom in, and such treatment seems to suit it well, for it is increasing rapidly.—W. WILKS, *Shirley Vicarage, Croydon.*

The dates of the following Rose shows to be held in 1887 have been fixed. Ryde, June 23; Bagshot, June 28; Moreton-in-Marsh, June 30; Crystal Palace, July 2; South Kensington, July 5; Sutton, July 6; Bath, Farningham, July 7; Dis, July 12; Edinburgh, July 13; Ulverston, July 15; Wirral (Birkenhead), July 20. With the exception of the Crystal Palace Show, all the above exhibitions are held in affiliation with the National Rose Society.

Cut flowers in New York.—According to the *American Florist*, cut flowers seem to be highly valued and fetch fabulous sums in New York, judging from the following retail prices: Rose W. F. Bennett, 1s. each; La France, 1s. to 2s. each; General Jacqueminot, 2s. to 4s. each; Niphetos, 7s. per dozen; Carnations, 2s. to 4s. per dozen; Lilac, 6s. to 8s. a spray; Violets, 6s. per bunch. If our British growers could realise such prices, they would think themselves handsomely remunerated.

Vegetable trials at Chiswick.—Comparative trials of the following vegetables, viz., Cabbages, Tomatoes, Cauliflowers, Onions, Turnips, new varieties of Potatoes and Peas are proposed to be made this season, under the direction of the fruit and vegetable committee in the Royal Horticultural Society's Gardens, Chiswick. Persons desirous of contributing examples of any of these objects for the opinion of the committee are requested to forward the same as early as possible to the superintendent, Royal Horticultural Society's Gardens, Chiswick.

London parks.—Replying to a question respecting London parks, Mr. Plunket gave the following particulars. The cost of laying out Kennington Park was nearly £5000, this sum being defrayed by the Treasury. The cost of buying and laying out Victoria Park was about £133,000, which was paid out of funds provided from the land revenue of the Crown. The amount (about £1500) for laying out Bethnal Green Gardens was paid by the Treasury. Battersea Park and estate cost £350,000, of which sum Parliament voted £105,000, £200,000 having been borrowed, and the remainder applied from proceeds of sales and rents. The maintenance of Trafalgar Square was £250 a year, exclusive of the cost of the water required for the fountains.

W. MILLAR.—We should say that your *Eucharis* is infested with the *Eucharis* mite.

F. STEEDMAN.—There is little doubt that your bulb is badly infested with the *Eucharis* mite.

Names of plants.—E. H. T., *Norwich.*—A very good variety of *Dendrobium apium*, sometimes called *D. album*.—J. B. K., *Leptotes bicolor*.—J. B. L., *The Orchid* flowers appear to be a species of *Bolbophyllum*; send growth or describe it; cannot name the leaf.—F. H. B., *Brainea insignis*; 2, *Lomatia glauca*; very rare; not in cultivation as far as we know; 3, *Lycopodium taxifolium*.—K. T., 1, *Boronia megastigma*; 2, *Grevillea Priestii*; 3, *Acaea argyrophylla*; 4, *A. Drummondii*.—N. Y. Z., 1, *Lelia harpophylla*; 2, *Pithecochloa Sanderiana*; 3, *Dendrobium crassifolium*.—*Bianca*, 1, the true *Cycl-gyne cristata Lemniana*; 2, *Cattleya*, a good form of *amethystoglossa*; 3, *Begonia Carteri*; 4, *Pitunia nobilis*.—G. Thoms., 1, *Erica melibtheca*; 2, *Acaea Drummondii*; 3, *Adiantum formosum*; 4, apparently a *Hakea*; cannot name without flowers.—T. G. C., *Succisa*.—Your *Scelopendrium* is only an ordinary ugly form.—E. H. W., *Warrington*, 1, *Niphobolus lingua*; 2, *Davallia solida*; 3, *Lilonia floribunda*; 4, *Justicia flavicomis*; 5, *Dipterocarpus Herbsii*.—*Georges Soud*, 1, *Skimmia oblata*; 2, *Emponyus radicans variegatus*; 3, *Cyrtomium lucidum*; 4, *Trichomanes parvulum*.—K. G., *Epsom*.—Your aquatic Fern is *Ceratopteris thalictroides*.—E. J. H., *Glasgow*.—A curious form of *Antholyza aethiopica*.—G. V.,—Your seedling *Amaryllis* is an ordinary good form of *A. amica*.—J. B., *Cattleya Trianae* delicate.

Names of fruits.—J. Sals, *Elkbridge*.—Apple, Golden Spur; Pear, Beurré Diel.

WOODS & FORESTS.

PINUS PONDEROSA.

THE wind-swept Isle of Anglesey would, perhaps, hardly be considered as a very favourable habitat for the above Pine, but that it is so was clearly enough demonstrated to me a short time ago when making a rather hurried visit to Baronhill, the beautiful Welsh residence of Sir Richard Bulkeley, Bart. In other and colder parts of the same island, and in company with the beautiful and equally hardy *P. insignis*, it braves in a remarkable and commendable way the keen, searching winds blowing in from the Atlantic Ocean. These, and similar instances that have either come under my own notice or been recorded to me of late, impress upon me how valuable a tree for planting in certain positions this Pine is, and that, judging from how seldom it is to be seen in our woods and grounds, the sooner its good qualities are brought prominently under notice the better, for it is certainly a valuable acquisition to our stock of forest trees. As an ornamental tree, I am by no means disposed to say much in favour of *P. ponderosa*, its rather lax, tortuous foliage and gaunt appearance imparting to it more of the picturesque than the beautiful. The branches are remarkably stout and inclined to droop, arranged in sparse whorls, and usually but thinly clad with foliage, the latter being almost confined to the branchlet extremities. Great variation is noticeable in the lengths of the leaves of various specimens, but in fair-sized trees about 7 inches or 8 inches is the average; they are stiff and somewhat di-helved, and of a deep dark green, and usually arranged in threes. In large specimens pollen cones are fully produced, and as they are of large size and, when ripe, of a bright yellow, they contrast nicely with the deep green, tufted foliage. These male flowers or catkins are remarkably persistent, those for four or five years back still adhering thickly to the branches, a tuft of the long leaves marking off with great accuracy the divisions of each year's growth. The cones are ovate in shape, 4 inches or more in length, with stout foot-stalks, and are usually produced in clusters.

A peculiarity of the bark, apart from its pretty and distinct colour, is the way in which it is divided into flakes of often 5 inches square, but for all this the trunk is tolerably smooth and may, by a practised eye, be distinguished from any other at a considerable distance.

The timber of *Pinus ponderosa*, as grown in this country, is heavy and full of resin, with a very agreeable smell and prettily marked; but this is referring to a tree of nearly fifty years' growth, others of smaller size and planted from twenty to twenty five years having produced a much lighter and less solid wood, and with a marked falling off in the quantity of turpentine, as noticed in the larger specimen. The timber of no other Pine that I have had the chance of cutting up contained such a quantity of resin as did that of the large one above referred to, and the strong resinous smell given off was, in my opinion, only equalled by that of a 70-foot-high tree of *Abies grandis* that we not long ago had to cut down.

To Scottish enterprise are we indebted for the introduction of this gigantic Pine, it being sent home from Oregon, in 1827, by Douglas, where, as well as in California, it is found in great abundance. A person who resided for some time in a district where this Pine abounded tells me that the average height of the trees was fully 180 feet, and he has measured the trunks of some fully 5 feet in diameter, but there were many larger. Where the trees grew in close proximity to each other, and were destitute of branches for more than half their height, the sight of colossal stems was, he likewise informs me, almost indescribable. Some fine specimens of this Pine may be seen in various parts of the country—trees of from 50 feet to fully 60 feet in height, half as much in spread of branches, and with stems girthing as much as

8 feet at a yard from the ground. When allowed plenty of room for development of the branches the diameter of the spread of these almost equals the tree's height, one case in particular that has just come under my notice being a tree 55 feet high with a spread of branches of 42 feet. In such cases the branches are usually cone-bearing down to within a couple of yards of the ground.

Soil would not seem to influence the growth of *Pinus ponderosa* to any great extent, for in my mind's eye I am now picturing specimens growing in sandy soil, still clayey loam, rocky *abris*, and reclaimed peat-bog, and with but little difference so far as external appearance is concerned. The large specimen, the wood of which is referred to above as being so heavy and full of turpentine, was growing in almost pure gravel, while the Anglesey specimen is on shallow loam of a sandy texture, but others in peaty soil are likewise hale and sound. The nursery management of this Pine is not by any means difficult, for the ordinary treatment bestowed upon the Scotch Fir and Corsican Pine suits it well. It grows very rapidly in its young stages, and is fitted for planting out at a comparatively early age, sooner, indeed, than the majority of nursery stock. On the Continent *Pinus ponderosa* is receiving attention, for it is included in the list of trees which the Prussian Government is introducing as useful additions to the state forests. Let Englishmen, therefore, not be behindhand in utilising a tree that is so well suited for our climate and soil.—A. D. WEBSTER.

— In THE GARDEN of February 12 (p. 153) I notice an account of this Pine; I cannot agree altogether with the description of it. In the Roosenai Valley, British Columbia, it is a most splendid Conifer, old or young, but especially does one notice its grandeur as an old tree; its great height and straightness of stem, its rich, tawny, red bark with the sun shining on it, give it extraordinary beauty; its huge proportions, from 15 feet to 25 feet in circumference, and the number of noble trees of its kind scattered in park-like terraces throughout the valley, make it a tree to be remembered. The want of lower branches in its old age does not detract from its beauty, but, like the Scotch Fir, only adds to its majesty. Just before I left I rooted up about sixty seedlings, which are now doing well in my garden here; its timber is valuable.—T. BATE, *Kelsterton, Flint*.

THE PROFITS OF UNDERWOOD.

A VAGUE idea possesses the ordinary mind that those delightful coppices of Kent and Sussex through which the train flashes us are of little or no value. In summer they are supposed to be leafy strongholds of rabbits and pheasants, delightful places to wander through in quest of Primroses or Hazel nuts, and in winter they are held to serve at least to break the monotony of the landscape and to afford shelter. This is the sum of their purpose to a casual observer. Instead, however, of coppice and hanger being unproductive game coverts, they are singularly valuable, and more than one fortune in our home shires of late has been built upon a proper appreciation of their value. The main cause of existence and the prime source of their profitableness are the neighbouring Hop gardens, from whence come insatiable demands for poles of Chestnut or Ash, 10 feet to 15 feet long, and as straight as Nature can be induced to grow these tough and lasting woods. Of late, however, foreign Hops have been entering into competition with English, duty-free and cheaper, the result being that growers have had to curtail their Hop gardens, making good for a long time the waste of worn-out poles by bringing in those from the disused portions of their holdings, and this has told adversely on the value of the English jungles.

But Kentish woodlands make other things besides supports for Hops. Leaving out of sight for a moment the subject of the capitalist, who regulates the growth of large tracts of otherwise almost useless ground, and can afford to wait while his material matures into real timber and heavy wood, we will glance at the way in which the coppices of the southern wolds

have made the Kent and Sussex yeomanry for many years amongst the most prosperous of any peasantry. The enterprising man who would go in for this species of woodcraft must have a little money in hand to begin with. There is first of all a deposit to be paid upon the ripe hanger he has chosen, and which, may be, keeps the north wind from his whitewashed cottage that nestles near it. Moreover, it will be necessary for him to devote himself to the woodlands during the winter months; thus he must have something to support the little ones during such a period; but given this, it is all plain sailing. His holding is fit for cutting, we will suppose, and when the leaves are down he sets to work at once. His boys go in and with light billhooks take off the small branches and twigs from the standing Ash and Chestnut poles which have been grown so close together, that they have spent most of their time in racing up for the blue sky only visible overhead. The father comes next, and with a sharp axe fells these saplings low down with judicious care, remembering that if the rain finds lodgment on the stumps, it will certainly rot them, and leaving here and there a leader on the pollard boles to preserve the vitality of the tree and tempt it to break afresh in the spring. As these poles fall they are dragged out to the riles by willing hands, where the good wife scrapes them clean of their soft rind and takes off the useless tops or the knots with her wood knife. He looks to receive from the grower of Hops a sum which shall repay his output on account of this single work alone. All the rest of the coppice produce should be clear profit, and it is more various than would be supposed. The spray-ware, as distinct from the larger growths, produce all sorts of wood upon which in the right market a price can be made. Nothing is wasted. To begin with, the chips and the litter go home in barrows and aprons to make a comfortable pile of winter fuel, rendering the family independent of charity coal, which is but poor fare; then in an ascending scale come the Hazels, which the lads put together for fire pimps, while the larger material, too small and various for anything else, goes into fagots and stacks, and sells subsequently for firewood. Straight rods of about the height of a man are valued by the coopers as barrel hoops; the long, straight six-year-growth of the Hawthorns are known as chisel rods and are taken up by the village smiths. Big material and windfalls are cut up into lengths for charcoal, and Oak bark, if there is sufficient, goes to the tan yards. Chestnut wood, if of proper size, is split into halves for heads for hurdle gates, and when the ground is cleared of all these, then the knotty Blackthorns, the contorted ground Ashes, gnarled Oak saplings, and the wands that have been clasped overtight by the Woodbine and wild Hop are cut and dried for walking sticks and umbrella handles, the long, straight Holly shoots peeling to a beautiful whiteness and being in high demand for carriage, and others of shorter lengths for the handles of cart whips.

It will readily be understood how the cutting, carrying, cleaning, and preparing of all this takes time, but returns in a reasonably good season a sound profit. Therein lies its value, for it is work of the idle winter time when Hodge would otherwise waste his substance at the village tap, and the thiu, white visages of his little ones tell of uncertain wages and an empty meal-tub at home. But the frugal yeoman who can produce a deposit at the annual November wood sales may find work for all hands till the spring comes again; and work, moreover, which is delightful because it is for himself, which braces his muscles to renewed exertion, which teaches him frugality as well as thoughtfulness, and fills life with an interest which the daily drudgery of an alien task could never do. The drawbacks are not very many. Amongst them are the rabbits, which, especially in hard weather, gnaw off the bark of underwood as high as they can reach by sitting on their hind legs; the trespassers, again, who steal the best of the Holly and Whitethorn sticks, breaking fences and pulling down boughs. Nor do the coverts yield their silent crops oftener than once in seven or eight years, much in this respect depending on soil and aspect; but, on the other hand, their harvest is a movable festival, which can conveniently be put off for a year or two—a unique characteristic amongst crops—until better and more paying seasons shall come. The value of the

spray-ware and light material on a cant of woodland is fairly steady, but the value of the poles fluctuates with the prosperity of the Hops. In a good year an acre of prime Chestnut, ten years old, may be worth £60; in a poor season for Hops not half so much. Ordinary underwood, again, the wild garden of Foxglove and Dog Rose carrying some 3000 Hop-poles per acre, may be valued at £15 per acre; and so on, in fluctuating steps of merit, which only a keen judge or one born on the land can properly assess. But, high or low, there is a value little acknowledged in the Kentish and Sussex woodlands, and a value which deserves recognition all the more because the landlord's and the tenant's interests run together here at least.—A KENTISH MAN.

* * * Prices for underwood have lately been very low—so low as to make it hardly worth the selling. We have seen it sold for not more than £5 per acre, ten or eleven years old.—ED.

ESTATE MANAGEMENT.

THE HOME FARM.

THE outlook as regards agriculture and the land interest generally is so dark, and the influence of the depression is and will be felt so sensibly upon horticulture and arboriculture both, that I venture to think no apology is necessary for introducing this subject into these pages so generally read by those interested in such matters.

The first subject to be considered on any estate is the home farm, a very old institution indeed, originating at a time when most large country houses had to depend much more upon home-grown produce for a supply of many household wants than they do now, and which then no doubt fulfilled many useful functions. Times are altered now, however, and I think I shall be able to show that there is much need for an alteration of our home farm system if it is in future to render good service to agriculture generally, or to those who keep up home farms for private purposes. It is perhaps necessary in the first place to define clearly what is meant by the home farm, for although the name is familiar enough, it has rather a vague meaning. Suffice it to say that the home farm is that portion of the estate generally set apart by the proprietor to supply his establishment with dairy produce, poultry, eggs, bacon, sometimes beef and mutton, corn and hay for his stables, and to grow such crops as may be necessary for the house or farm itself. It also supplies the labour for leading and fetching and carrying generally for estate purposes. The home farm manager is also supposed to keep a correct debtor and creditor account of all transactions, and generally to manage as thriftily as possible, for, ostensibly at least, he is supposed to make the farm pay, and to supply the house with produce as good and as cheap (if not better and cheaper) as it could be supplied elsewhere. On the contrary, however, home farms are proverbial for their inability to make ends meet, not to say mismanagement, for waste, bad farming, and in numbers of instances they help to place the proprietor in an awkward position towards his farm tenants, for when it becomes known or suspected, as is usually the case, that the landlord with capital at his disposal cannot farm his own land profitably, the question arises, how can he expect his tenants to do it, and live and pay a rent over and above at the same time? I could name numbers of home farms that are in this position at the present time, and some that never at the best times did more than cover expenses. In this, I ask, not a discreditable state of things? What is the cause of it, and how can it be altered? I maintain that the home farm can be made to pay, and that it ought to set an example to all the tenants on the estate in that respect, instead of doing the contrary, as is not unfrequently the case. The cause of failure is simply bad management. Appearances go for nothing. It is not long since that the whole of the prize stock of a gentleman (deceased) were put to the hammer, and the whole farm reduced, because of the losses it had entailed. By whom

are estates and home farms managed? is a question which, if answered fairly, would put matters in a true light. The answer is, that they are managed, as a rule, by men who are ignorant of the duties that devolve upon them. They are lawyers residing in town, or agents or factors who are sons of gentlemen in reduced circumstances, officers of the army, the clergy, &c., and have little or no practical knowledge of estate work, which can only be acquired by patient application and experience, like anything else. The probationary career and education of such managers often consists of nothing more than a few months' or a year's residence on some gentleman's estate under an agent, who is perhaps not much older nor much wiser than themselves, but may be a little richer by the fees they pay him for the experience they are supposed to pick up at random while under his charge. A looser and more irresponsible way of preparing young men never previously subjected to the discipline of business habits could not be devised, and results abundantly prove it. Of the numerous estate appointments filled by men of this stamp, probably two-thirds fall to the lot of incapables. Landowners are often victimised by such men, thrust upon them through the interest of friends. Such estate agents take the lighter duties of the estate themselves, and if they are fortunate in securing the services of an intelligent bailiff or foreman, who is honest and trustworthy, they may get on and even learn something, but as often as otherwise perfectly illiterate men are put over the home farm who have no intelligent knowledge of agriculture, and who care less for it than those who employ them. The consequences are as has been before stated, viz., that the farm becomes a dead loss to the proprietor instead of a profit, and a demoralising example to all who farm land on the estate. The mistakes of omission and commission such agents make otherwise in the general management of an estate are too numerous to mention. Every important question affecting tenancy, rents, agreements, and valuations, which can only be determined by sound practical knowledge and experience, have to be finally submitted to, and settled by, them, and the most random and utterly foolish decisions are given, the landlord or his tenants being invariably the victims to suffer by them.

There are, of course, some home farms that are profitably conducted, but they are conducted by men who have been "bred to the plough," as it were, or those who have honestly mastered the business through sheer necessity. I know of one or two examples of home farms that pay under such circumstances, but generally they are few and far between.

The fact is the vocation of the home farm has gone long since in its original sense. Few gentlemen's establishments depend upon it for supplies, and it would be far better to divest it of all connection with the house and devote it to the purpose of showing the tenants on the estate how to farm well and make farming pay. So long as landlords cannot farm profitably themselves they cannot expect anything else but a constant clamour for reduction of rents from their tenants. A well-managed home farm is, or should be, a potent factor in sustaining the valuation of all the other farms near it, and *vice versa*. It should not be too large, but it should embrace every feature in the shape of crop and stock that can be produced in the district, and, above all, it should be managed on scientific common-sense principles and be made as remunerative as it possibly can be, and that, too, without any fictitious aid from home sources. There is nothing whatever to hinder this being accomplished on estates. It is simply for the proprietor to resolve that it shall be, and put the enterprise in the hands of a competent man who would be partially paid by results—say so much in wages, and the remainder in the shape of interest on, or a proportion of, the profits. First give a man a fair wage and a chance of increasing it by his careful management of his charge, and the chief force to ensure

success is set in operation. As it is on home farms at present, the presiding genius is usually an encumbrance and the most expensive individual on the place, his man perhaps not much better, and the general staff excessive and its members indolent. On no other principle can the present condition of the home farms be explained, and all are agreed about their uselessness and bankrupt condition even at the best of times, when other people manage to live and make money by farming under exactly the same conditions of soil and climate.

There is much need at the present time for landowners to exert themselves in this direction and set an example if they wish to preserve anything like a shadow of their former incomes from estates. Notwithstanding the reductions that have been made in rents, either by periodical remissions or permanent reductions, the farmers still clamour for more, and are, at the same time, neglecting their farms to an alarming extent. Nothing whatever is being done to improve them; fences are neglected, and culture has reached a lower ebb than it has done for generations, owing to the uncertainty of the times, ignorance and want of enterprise, and the bad management of estates.

But where are gentlemen to find competent estate agents, and how are they to know them when they find them, are questions that will no doubt occur. All that can be said is that there are plenty of capable men, and they can be found, if inquired for, in the right direction. A gentleman, unaccustomed to practical matters himself, might not be able to estimate any man's capabilities offhand, but he is ill off if he cannot find others able to do so; and if the worst comes to the worst, a man can be appointed to a post conditionally. It would hardly be believed that men have been appointed to factorships on estates who hardly even understood the rudiments of the business, who had never read a book on the subject till shortly before, who did not know where to search for information on the subject when they wanted it, and who could never open their mouths in the presence of practical men without exposing their ignorance; and yet such appointments have been made, and made often. What else than mismanagement can be expected under such circumstances? AGENT.

COST OF FIREWOOD.

THE question, "What will it cost to prepare a ton of firewood?" is more easily asked than answered. In the west of England it would cost 6s. to prepare a cord of wood fit for burning in an ordinary cooking grate and to store it away under cover. Oak and Elm are more difficult to cleave than any other wood, and may cost a little more. The best way in which to burn wood is on the hearth. In this way only the largest pieces would require cleaving; in a general way 3-foot lengths are quite convenient for such fires. The next best plan is to have long and rather narrow grates, consisting of no more than three front bars. These grates should be from 20 inches to 2 feet long and 10 inches wide in the middle, gradually narrowing at each end to a point; the front bars should curve slightly outwards. Four inches are ample between the bottom of the fire-bars and the hearth. In the ordinary kitchen range the draught is not only too great, causing quick combustion, but the deep sides and backs of such grates consist of much dead surface that takes its share of the heat, but gives off but little in return. This mode of burning wood is about as costly as purchasing coals at 21s. per ton. There is nothing gained by having the logs too large, but much loss if too small, as small pieces burn much faster than large ones. For a grate of suitable form and length logs with a circumference of from 12 inches to 15 inches are the best—*i.e.*, these sizes should predominate, but there must be a fair proportion of smaller pieces to ignite them. Cleft wood is, however, better than round; therefore all pieces 9 inches and upwards in circumference should be split into two. Cleft wood always ignites quicker than round wood. A storage for the wood should be provided. It need not, however, be of an expensive character. J. C. C.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

FLOWER GARDEN.

WILD WHITE DAFFODILS.

I HAVE suggested to Mr. G. Maw, who tells me that he hopes this spring to work upwards from Southern Spain, through Portugal, to the Pyrenees, that he should make a special effort to discover, or re-discover, the wild originals of the white Trumpet Daffodils of our gardens. There are, I think, fairly good reasons for supposing that such exist somewhere in the Pyrenees, in Portugal, or in the less known of the Spanish Sierras. Perhaps Portugal offers the most promising hunting-ground. A good deal of botanising has lately been done in the Pyrenees without the bringing to light of any white Ajax except the very small one from the Gavarnie district. And when we look southwards into Spain proper we see the *Corbularias* comparatively soon taking the place of Ajax; although the country, it is true, is large, and towards its north and west may yet give us new and interesting varieties of the latter. Portugal, although as yet barely scratched, has already yielded some most interesting Daffodils, chiefly owing to the industry of Mr. Tait, and we may reasonably hope that these are but an instalment.

The little Gavarnie *moschatus* is so variable in form and has already shown so considerable a tendency to increase in size in cultivation, that it has until lately been my opinion that it might possibly be the ancestor of all our larger garden kinds. But in reading Mr. Tait's notes on the *Narcissi* of Portugal, I have been much impressed by certain observations of his. He reminds us that when the older writers, such as Parkinson, mention Spain as the habitat of so many *Narcissi*, it is to be borne in mind that in their time the term Spain included Portugal. And, having consulted the best works on Spanish botany, he has come to the conclusion that Portugal yields more *Narcissi* than Spain. Lastly, he states, possibly from some information received, that he hopes to find "*N. moschatus*" in the mountains of North-east Portugal.

Now, I think we seem to be fairly on the way to trace back all our old garden Daffodils to Continental wild forms; already there are but few gaps remaining in this identification, and we may expect these to be filled up before long. Taking the groups of Ajax in order, according to the current classification, we find the types of garden pseudo-*Narcissus*, known as *cambricus*, *principis*, and *Telamonius*, to be wild in Italy, as are also the principal major varieties, such as *major*, *maximus*, *Tenby*, *spurius*, and *Tottenham Yellow*. From personal observation in Italy, I cannot doubt that all these are to be referred to Italian wild plants. Then minor has lately been found in the Maritime Alps; *lorifolius* is undoubtedly Pyrenean; and although the origin of bicolor (very near to *lorifolius*) has for a while been somewhat of a puzzle; yet we are now getting flowers from the Pyrenees and Portugal which come near enough to the typical garden form to satisfy us as to its ancestry. By analogy we should expect the principal types of the only remaining section—that of *moschatus*—to be similarly represented by wild sorts. Parkinson, we know, describes four white Spanish Daffodils,

of which one only, the smallest, has hitherto been identified in its wild state—if indeed it has been identified, for there are reasons, which I need not now adduce, for doubting whether the Gavarnie plant is the lesser Spanish white of Parkinson. But it is likely that they will be re-discovered among the Pyrenees or the mountains of Spain or Portugal. Our expectation is strengthened by remembering that the Dutch have long had in cultivation certain large forms of *moschatus*, which, like the rest of their Trumpet Daffodils, were probably obtained at first as wild plants, for in old days they seem to have raised no seedlings of these, but to have confined this work to the *Tazettas*. I venture, therefore, to predict the finding before long of large wild white Daffodils.

G. H. ENGLEHEART.

HALF-HARDY ANNUALS.

THESE are much prized for summer and autumn decoration. Amongst the best of them are *Asters*, which are easily grown and useful in a cut state as well as for filling up vacancies in herbaceous borders. The *Victoria* and dwarf *Chrysanthemum* flowered kinds are the best for general purposes. Some sow and grow them in heat; but that is a mistake. They do best in cool quarters. About the middle of this month plant 3 inches or 4 inches in thickness of light sandy soil on the top of a spent hotbed, and in this sow the seed in shallow drills, covering the whole lightly with soil of the same character. Keep the lights close, and shade from hot sunshine until the plants appear, which will be in a week or ten days. Then gradually give more air, and when sufficiently large transplant into cold frames, using the same kind of soil as that just named, but this time 3 inches in thickness, with a thin layer of horse manure, into which the roots will ramify, and the plants will lift with good balls of soil attached to them; thus managed they sustain no check when transferred to their permanent quarters. When growth commences give plenty of air until the lights can be drawn off altogether. If a hotbed is not available, sow in shallow boxes and place them in a cold frame. Keep them shaded from bright sunshine, and the seeds will soon germinate. Let the young plants be put out about the middle of May, selecting, if possible, dull showery weather for the operation. When a start has been made no attention will be required, except giving the roots a good soaking with liquid manure once or twice during the summer, and perhaps placing small stakes to tall-growing kinds to prevent them from being injured by wind and rain.

PORTULACAS.—Double varieties of these find, as a rule, more favour than single kinds. An open, sunny sloping bank or the top of a rockery which is warm and dry suits them admirably. They should be planted in bold masses in such a manner that one colour may set off to advantage that of its neighbour. They make capital edging plants in the kitchen garden in connection with stone or brick. A compost consisting of light sandy soil, with which leaf-mould and peat have been freely mixed, just suits them. Under this should be put some well rotted manure, and the whole should be trodden down very firmly. Then sow the seed early in April, covering it lightly. During the summer give a good soaking of water now and then should the weather be hot and dry. Where such a seed bed cannot be had, and they have to be planted in various parts of the garden, the seed should be sown in gentle heat about the middle of March, and the young plants should be pricked out into pans or boxes as soon as large enough to handle; keep them cool, and plant them out into their permanent quarters towards the end of May.

PHLOX DRUMMONDI.—Of this so many varieties may now be had, that they make a grand display during the summer. Planted in a mass in an open position they are very effective. Growths made

freely after planting should be pegged down so as to cover the soil quickly with foliage and richly-coloured flowers, which continue in perfection until cut down by frost. Sowing the seed about the middle of March in gentle heat, pricking off the seedlings into boxes and keeping them cool, and thoroughly hardening them off previous to planting them in the beds, are all that is required in order to have them in good condition.

ZINNIAS.—Of these the double forms are preferable to single kinds for border decoration, their colours, as a rule, being more varied. They look well in masses in the flower garden, where, however, they must have a rich soil in order to bring out their colours in their true character. When planted in a bed their shoots must be pegged down as fast as they grow, otherwise they become leggy, *ie.*, when planted thickly; but when planted in other positions, at distances of from 9 inches to 12 inches asunder, they assume a bushy character, and should be staked to keep them in good form. The seed should be sown in gentle heat towards the end of March, and the young plants should be removed to cooler quarters as soon as they are visible, or they quickly become drawn, which tends to weaken them considerably, and a poor show of bloom during the season is the result.

SALICIGLOSSIS.—The variety of colours to be found amongst seedlings belonging to this genus renders them very attractive. Planted in groups of three or five together in herbaceous borders or in lines where a suitable amount of space can be given them, they well deserve all the praise they get; when in lines, a distance of 9 inches from plant to plant is sufficient. The support of a small stake to each plant will be of service, as, being rather weak in growth, they are liable to get injured by wind. When sown and treated like *Zinnias*, no plant with which I am acquainted better repays any trouble that may have been bestowed upon it both in the way of floriferousness and variety of colour.

CELOSTIA PYRAMIDALIS.—It may not be generally known that plants of this *Celosia* are well suited for bedding, in the south of England at least. When planted alternately in a bed with sub-tropical plants, such as *Grevillea robusta*, *Acacia lophantha*, or *Ficus elastica*, they are very effective, the deep green foliage of the *Ficus* contrasting strikingly with the richly-coloured plumes of the *Celosia*. The seed should be sown in gentle bottom-heat early in March, and the young plants should be potted off singly in small pots. They should be kept in a temperature of from 60° to 70°, and set close up to the glass. Pinch the point off each plant when about 3 inches high; this will induce some four branches to break, which will in time bear as many flower-plumes. When well rooted and before they become potbound, shift them into 5 inch pots in light, but moderately rich soil, and when nicely established gradually remove them to cooler quarters, and thoroughly harden them off preparatory to planting them out in the beds.

CHRYSANTHEMUMS.—Summer-flowering single varieties of these are useful plants with which to fill vacant places in herbaceous borders or shrubberies. Being so showy in the way of flowers renders them useful for cutting purposes. The middle of this month is early enough to sow the seed, which should be done in gentle heat; prick off the young plants when large enough to handle into boxes or a cold frame, in which gradually harden them off and plant them out at the end of May or early in June, according to climate and other circumstances. *Segetum*, *Lord Beaconsfield*, *Burridgeanum*, and *W. E. Gladstone* are some of the best sorts. E. M.

Variiegated Kales in the flower garden.—These when well coloured have a good effect, and hide the naked appearance which is so often seen in flower gardens during the winter months. In order to keep the plants dwarf and compact and to develop their colour they must be grown in poor soil. The seed should be sown in May, and when the young

plants are large enough to handle they should be pricked out in a sunny border, about a foot apart, where they may remain until October, when they should be planted out. To have a good effect, the stems, which must be of equal height, require to be hidden by sinking the plants in the soil up to the bottom leaves. They vary in colour, some being white, pink, and purple, and there are also different shades of green, brightly veined. But care should be taken to secure seeds of the best strain, and in planting out to select only the finest and brightly-coloured varieties.—C. COLLINS.

Erica carnea.—This may be regarded as the harbinger of all the hardy Heaths that yield us such a wealth of blossoms throughout the summer and early autumn months, and where a little sheltered by an overhanging shrub or in rather a favoured nook, it is, despite the severe weather we have had, already in bloom. The flowers are, like most of its class, borne in great profusion, and are of a very pleasing tint—a sort of rosy red. There is also a white-flowered variety, which is not so common as the other, and beautiful though it be when sheltered, the blooms are often liable to be disfigured by wet weather when in the open ground. Known also as *Erica herbacea*, this little Heath is well suited for a rockwork nook, or as an edging to the larger *Ericaceae*, while I have seen it potted up and used for indoor decoration during the early months of the year. So treated, its blooms expanded beautifully, and it formed for some time a very attractive feature.—T.

Callas in masses.—I like "J. G. H.'s" suggestion regarding these (p. 163). The finest individual mass ever seen by the writer was treated as this writer describes. Small offsets were cleared away, all the strong ones left, and the plant was potted on till the largest pot obtainable was reached; then it was shifted into a tub, in rich material, and top-dressed with rotten manure every year. It thus developed into a large bush, and was a sight to see and admire when crowded with fine foliage and with from a dozen to a dozen and a half of blossoms. Such plants are invaluable for staircases, front halls, large bow-windows, conservatories, &c., though for general decorative purposes they will never supersede the one-crown plants in 6-inch or 7-inch pots now grown by thousands and tens of thousands. A very common way of growing the latter is to plant them out in rich soil about the end of May. With rich root-runs, abundance of water, and free and full exposure to light and air, the single-crowned masses grow up with a sturdiness and vigour they seldom attain in pots or under glass. These out-of-door plants, lifted about the end of September and placed in cool pits or houses, flower well throughout the winter and early spring.—HORTS.

SHORT NOTES.—FLOWER.

All sorts of **Daffodils**, says Mr. Hartland, writing from Cork on the 25th ult., are now a blaze of bloom in the open, and *Erica carnea* a sheet of pink.

Violets.—I send you a few flowers of *Comte Brazza's* Double White and *Marie Louise* Violets. I should like to know what you think of them. They are grown on the Cotswold Hills, and we pick from the last-named variety from the end of September to the beginning of May.—W. G. N.

The blooms received were certainly very fine; indeed, as fine as any that have come under our notice.—Ed.

Echeveria secunda.—This plant, so useful as edgings and outlines in the flower garden, may be kept during winter in many ways. A plan which we saw at Syon House the other day may, however, be new to some. Ridges were thrown up in a cold frame to the height of 12 inches, and on each side of these the plants were dibbled. By this way the plants are free from drip, which is often fatal to them, and space is also very much economised.

Primula obconica.—I am glad to find someone speaking favourably of this *Primula*, as I do not think there is a more easily grown or more satisfactory plant than it is for a cool greenhouse. I had a seedling given me last year; it commenced to flower in May, and has never been out of flower since, and I expect it will bloom the whole year round. It has had two shifts, is now in a 6-inch pot, in rich light soil and carries twenty heads of flower, and has leaves from 3 inches to 4 inches across.—H. B. R.

A good combination.—Tall and early **Daffodils** and *Nicotiana glauca* in a small bed cut out in the Grass and with a background of dark shrubbery. When the **Daffodil** leaves wither, the white **Tobacco** springs up and fills the bed, being a hardy perennial here. Nothing can be more

beautiful than these white **Tobacco** flowers towards dusk, seen against the dark shrubs, and filling the whole garden with their scent. They are an irresistible attraction, too, to some of the larger hawk-moths.—G. H. E.

NOTES OF THE WEEK.

Iris reticulata.—Messrs. Kelway, of Langport, have just now many thousands of *Iris reticulata* in full bloom—a grand sight. Although fully exposed to the east, they have not sustained the least injury from the late cold winds, which have been so trying to many plants.

A correspondent asks for *Edwardsia*. He can obtain *chilensis*, *grandiflora*, *macrophylla*, *microphylla*, and *M'Nabiana* at Messrs. Rodger, McClelland and Co., Newry. Mr. Smith, of Newry, offers the rare *Stuartia pentagyna* and *Gordonia pubescens*.—FRANK MILES.

Crocus Imperati has been in full flower here since Feb. 9, *C. susianus* followed on Feb. 16, and *C. reticulatus* on Feb. 19. *Bunardicus* and *Sieberi* are in bud, and other species coming on fast. They are all in sandy soil on a sunny rockery. *Galanthus Elwesii* and *Cyclamen Comm.* are also in full flower.—M. P. FORSTER, *Leisberg, Northumberland.*

Spring flowers.—We have received from Miss Owen a charming gathering of spring flowers from her garden at Knockmullen, Gorey. Amongst them are many varieties of *Crocuses*, both large and small-flowered; also *Primroses*, *Anemone fulgens*, *Narcissus minor*, *Erica carnea*, *Hepaticas*, and others, all in great beauty and showing that spring flowers are more advanced in that part of Ireland than with us.

Vernonia cinerea is a beautiful variety that gardeners would welcome could they buy it in nurseries, as it is a pretty plant and particularly well adapted for cutting. It reminds one of an *Ageratum* in flower, the small tassel-like blossoms being produced in much the same way, and are of a pale mauve-purple. It seems to be a shrubby plant, judging by the specimen in the *Begonia* house at Kew, which rejoices in the name of *V. cinerea conyzoides*.

Billbergia speciosa.—We have noticed from time to time the finest *Bromeliaceae* plants as they come into bloom at Kew. This *Billbergia* must certainly be added to the list of the very best kinds, as few others have such a good effect when in bloom. There is nothing remarkable about its growth, which is the same as that of most other *Billbergias*, and the flower-spikes are borne in much the same way as others, being long and slightly pendulous. The flowers themselves are long, pale green tipped with purple, but the flower-leaves or bracts are large and numerous, and of a vivid carmine-crimson, so that they are very showy. We do not know if this species is to be had in nurseries, but if so it is one of those we can recommend for general stove culture.

Amherstia nobilis.—This noble shrub, so seldom seen in gardens, is now in flower at Mr. W. A. Tyssen Amherst's garden at Diddington Hall, Brandon, Norfolk. The plant at Diddington is now about 10 feet high and some 14 feet through. Its flowers are borne in pendulous clusters, and there are from fifteen to seventeen flowers on each cluster. The flowers are large, of curious shape, the colour being a brilliant scarlet adorned with heavy blotches of gold. Such a gorgeous shrub as this can only be seen in large stove houses such as exist at Kew and Chatsworth, as it requires such a wide spread of branches. At Chatsworth there used to be a noble specimen in a house devoted entirely to it, and was known as the *Amherstia* house. It is an East Indian plant, and was figured in Wallich's great work called "*Plante Asiaticae Rariores*." Mr. Amherst promises us a coloured drawing and photograph of his plant, and, if possible, we will give a coloured plate of the plant in THE GARDEN.

A sweet-scented stove shrub, whose almost unpronounceable name is *Toxicophlea spectabilis*, is now one of the chief attractions among the South African plants in the Palm house in Kew Gardens. It is an Evergreen, having (as a pot plant) tall, erect shoots, with large and broad leathery leaves of a deep green. In the axils of each pair of leaves on the upper parts of the stems the flowers are borne. They are very small and white, but being very numerous they wreath the stems with clusters of white. They are deliciously fragrant, and quite scent that part of the house in which the plants are growing. It is easily grown, not requiring a great heat, as it is a Cape plant. It was figured in colour many years ago in THE GARDEN, but through some cause it is not generally grown, but those who are always seeking sweet-scented flowers in winter should make a note

of it. It is now a stock plant in good nurseries, and Mr. B. S. Williams, we believe, makes a specialty of it.

Forsythia forced.—Some examples of forced flowering bushes of the hardy shrub *Forsythia viridissima* may be seen in the greenhouse at Kew, where they create quite a distinct feature on account of being different from all other plants. The bushes are about 4 feet high and nearly as much through, and each shoot is wreathed with bright yellow blossoms, but, of course, unaccompanied by foliage. This shrub is easier to force than most others, and is a cheap plant in nurseries.

Agapetes buxifolia is a greenhouse shrub met with rarely outside a strictly botanical collection, yet it is among the prettiest plants one can have in bloom at this season in a greenhouse or conservatory. It is an evergreen bush with small leaves, something like those of the common Box, and each shoot now bears numerous tubular blooms nearly an inch long and of a bright red. It is very profuse in flower, and lasts a long time in perfection. It may be seen in one of the octagons of the temperate house at Kew.

Boronia heterophylla.—This welcome addition to hard-wooded greenhouse plants promises to be an acquisition. The flowers, which are bright violet, distinctly shaded with magenta, are produced in abundance. The leaves are in pairs, and at every joint there are four, and sometimes five, flowers. The side shoots are equally floriferous with the main branches, and even on the old wood flowers are plentiful. It is also sweet-scented. It is in flower just now in Messrs. Veitch's nursery at Chelsea.

The White Canary Island Broom (*Cytisus filipes*) is the embodiment of gracefulness and beauty when in bloom. It does not differ much from our northern kinds of Broom in growth, except that the slender shoots are pendulous, drooping on all sides of the plant in a most elegant way, and now that each shoot is covered with tiny white Pea-shaped blossoms, the elegance of the growth is emphasised. It is a greenhouse plant, we might say half-hardy, and one admirably suited for a cool conservatory. It may be seen in bloom in the temperate house at Kew.

The council of the **Royal Horticultural Society** have definitely arranged with the Commissioners of the 1851 Exhibition for the occupation of the conservatory at South Kensington for the society's meetings and shows, pending negotiations with the Royal Albert Hall Corporation. The entrance to the conservatory will be by the north-east orchard house, Exhibition Road, and the exhibitor's entrance on the east side of the Royal Albert Hall. Fellows of the society will be admitted at 12 noon on presentation of their last year's tickets, and the public at 1 o'clock on payment at the doors. Until further notice the price of admission to the public will be 1s. to the ordinary meetings, and 2s. 6d. to the larger shows.

National Carnation and Picotee Society (Southern Section).—The eleventh exhibition of this society will be held in the conservatory of the Royal Horticultural Society, South Kensington, on July 26. The same number of prizes is offered as usual, with the addition of the Turner Memorial prizes for six Carnations and six Picotees, to be competed for by amateurs who do not employ a gardener regularly. The statement of accounts is not very satisfactory, as there is a balance owing to the treasurer of £215s. 1½d. This deficiency is due to a larger amount than usual having been expended in prizes. The judges awarded £5 in extra prizes, the number of exhibitors being much larger than usual.

National Auricula and Primula Society (Southern Section).—The schedule for the present season has now been issued. The eleventh exhibition is to be held in the conservatory of the Royal Horticultural Society on April 26. Additional prizes are offered for species of *Primulas* and double *Primroses*, to be exhibited in pots or pans, and a number of plants may be placed together, so as to form a group. The Turner Memorial prizes for six show Auriculas will be competed for on that day. Rule X. has been altered, and now reads: "Seedlings, whether exhibited in collections or not, are eligible for certificates, due notice having been given to the secretary. Each plant must have the entry card correctly placed with it." The balance in favour of the society is £27 1s. 4d.

BOOKS.

THE HOMES OF WILD CROCUSES.*

LOVERS of Crocuses, as well as botanists, have in Mr. Maw's elaborate new book on the genus *Crocus* by far the most complete work that has ever been written. It is the outcome of a life-long study of the subject by the author, who has not been content to study Crocuses under cultivation, but has gone to the native haunts of the plants—has travelled, in fact, throughout the length and breadth of the regions where Crocuses grow wild to search for new species, and to glean knowledge bearing upon the life-history of the plants in a state of nature so useful and important to the cultivator. No one, then, could be better qualified to work out a thorough monograph of the Crocuses than Mr. Maw, who has in his work dealt with everything that has the remotest connection with the subject; the work even comprises a disquisition on the etymology

gravings from drawings by Mr. Danford, who, Mr. Maw tells us, travelled during the years 1877, 1878, and 1879 throughout Asia Minor, the region where Crocuses are most abundant. The engravings illustrating mountain scenery are most picturesque, and give one a good idea of those out-of-the-way regions in Asia Minor which are seldom reached by Europeans. Two of the engravings from the book are herewith given, one showing the native mountains of the pretty little *Crocus corsicus* at Corte, Corsica; the other the monastery of Sumila, nestling in a rocky mountain-side, near to which is the habitat of *Crocus vallicola*. Other engravings illustrate other *Crocus* homes, the most striking in the book being the Vallée du Lys, near Luchon, Pyrenees; Bulgar Dagh, in the Taurus, where *C. zonatus* is found; the city of Broussa and Mount Olympus, the headquarters of several beautiful Crocuses; Mount Argeus; the pretty island of Capri; while in Palestine, where a few species occur, an illustration is given of Bethlehem, and

devoted much space to it, but what he says is to the point and most useful. He says:—

Cultural directions for a genus so easily grown seem almost superfluous; but there are a few points to which it may be convenient to refer in dealing with *Crocus* as decorative plants. Taking the whole genus of about seventy species, they must be viewed as in continuous succession, from the beginning of August till April. Of these it is only the earlier autumnal, or the distinctly vernal species that can be relied upon in our climate for open-air garden decoration. Although all are hardy, and most of the winter-flowering species will flower in the open ground, those that flower in November, December, and January are so liable to injury by frost and rain, that they are practically worthless as decorative plants for the open garden.

For such, as well as for the less robust and less floriferous species, the protection of a brick pit is necessary. The bottom of the pit should be well below the level of the ground, and it should be filled up with about 1 foot in depth of fine river silt or sandy loam, the surface of which should be a little below

Corte, Corsica, the home of *Crocus corsicus*.

of the words "Crocus" and "Saffron." An outline of the contents of the work has before been given in THE GARDEN, but what we wish to direct attention to here is that part of the work dealing with the native haunts of wild Crocuses. In each account of the species, which number no fewer than sixty-nine, the native localities are named, as well as the conditions under which the plants are found wild. Some are found in high mountainous districts, others on sunny hillsides, others in valleys and open pastures—all of which information is invaluable to cultivators of these lovely wild Crocuses. Throughout the work are distributed numerous illustrations of places in or near the localities where one or other of the species grows wild. These engravings are for the most part beautifully done, and the artistic merit of the work is chiefly due to these. Most of the illustrations are en-

graving from drawings by Mr. Danford, who, Mr. Maw tells us, travelled during the years 1877, 1878, and 1879 throughout Asia Minor, the region where Crocuses are most abundant. The engravings illustrating mountain scenery are most picturesque, and give one a good idea of those out-of-the-way regions in Asia Minor which are seldom reached by Europeans. Two of the engravings from the book are herewith given, one showing the native mountains of the pretty little *Crocus corsicus* at Corte, Corsica; the other the monastery of Sumila, nestling in a rocky mountain-side, near to which is the habitat of *Crocus vallicola*. Other engravings illustrate other *Crocus* homes, the most striking in the book being the Vallée du Lys, near Luchon, Pyrenees; Bulgar Dagh, in the Taurus, where *C. zonatus* is found; the city of Broussa and Mount Olympus, the headquarters of several beautiful Crocuses; Mount Argeus; the pretty island of Capri; while in Palestine, where a few species occur, an illustration is given of Bethlehem, and

further east are places in Turkestan, the easternmost limits of *Crocus*. The extreme western localities in Spain and Portugal are illustrated, the Escorial and the Sierra Nevada from Grenada being particularly noteworthy, also of Cintra, that much-talked-of Paradise on the western coast of Portugal. These engravings give to the work an additional interest. There is a chart given showing clearly the range of the genus *Crocus*, from which it appears that the species are most abundant in Asia Minor in latitude 40°, for no fewer than thirty species are found there. The most northerly limit is in the Alatan Mountains and the most southerly in Palestine, the most westerly in Portugal, the most easterly in Turkestan. In Central Europe, and even in England, some species have become so naturalised as to appear wild—for instance, the common Dutch *Crocus*, *C. vernus*, which is found in various parts, as is also *C. sativus*. The culture of Crocuses is so simple, that Mr. Maw has not

the level of the surface of the adjacent ground. Proper drainage is essential; but this being attained, Crocuses during their period of growth delight in a uniformly moist subsoil. *Crocus vernus* in the Alps is more vigorous in hollow, moist places than on the projecting drier ground. It is convenient to separate each species by strips of slate or tiles, which may be buried below the surface, and the corms planted about 3 inches or 4 inches deep. A mulching of rotted Cocoa-nut fibre or finely sifted peat keeps the surface uniformly moist, and prevents the substratum of loam from clogging or caking on the surface. At the time of maturity of the foliage, which generally takes place about the end of May, water should be withheld, and the *Crocus* bed should be covered up and allowed to get quite dry till the end of July, when a copious watering may be given, or the pit exposed to natural rainfall. Crocuses are easily multiplied from seed, which should be sown as soon as ripe in July. Germination, however, will not take place till the natural growing period of the species. The autumnal species vegetate in the autumn and the vernal species in the spring succeeding the summer or autumn in which

* "Monograph of the Genus *Crocus*." By George Maw, F.L.S. London: Dulau & Co., Soho Square.

they are sown ; but some of the seeds lie dormant for one, two, or even three years before they vegetate. Seedlings take from two to three years to arrive at maturity. They should be left for the first two years undisturbed in the seed-bed, and then taken up and replanted. The replanting of the old corms every year, or every other year is advantageous ; and the clearing of the corms from the superfluous tunics, and the remains of the old decaying corms seems to encourage a vigorous growth.

Of the autumnal species suitable for the open border the following may be enumerated for successional flowering :—

C. Scharoani, orange ; early in August.	
vallicola, straw-coloured ; late in August and early in September.	
nudiflorus, blue ; September.	
pulehellus, lilac ; September and October.	
speciosus, blue ; September and October.	
iridiflorus, blue ; September and October.	
Salzmanni	} in the late autumn.
asturicus } lilac or blue ; October and November.	
Clusii	
cancellatus	
Cambessidese	
sativus	
hadriaticus	

These are succeeded by a long series of late autumnal, winter, and early vernal species, which are best grown to advantage under the protection of a brick pit.

Of the vernal species suitable for the border, the earliest is *C. Imperati*, flowering in February, followed by

C. susannus, or Cloth of Gold, in February.

biflorus	} Flowering from the end of February to the first week in April.
coriscus	
cruscus	
suaveolens	
versicolor	
vernus	
Tommasianus	
dalmaticus	
banaticus	
Sieberi and var. versicolor	
chrysanthus	
aureus	
sulphureus	
sulphureus pallidus and strictus	
stellaris	
Olivei	
minimus	
Balsans	

Of the *Crocii* recently introduced, many more of the vernal species will probably be found suitable for spring garden decoration, but in the above lists I have given only those which are more generally known and easily obtainable.

Holland, with its rich, light, alluvial soil, and Lincolnshire, with its "Trent warp," have been for many generations the sources from which the English market has been supplied with the varieties of the three or four species grown in English gardens. The last eight or nine years have put us in possession of nearly the whole of the known species of the genus, and they must be commended to the care of the Dutch and Lincolnshire bulb growers wherewith to further enrich our collections.

In collecting and transmitting wild *Crocus* roots, it is necessary to bear in mind the stage of growth of the plant. At the flowering-time the young corm is just beginning to be formed, and if the growing of the plant is interrupted, the little bud-like corm is likely to perish, especially if the plant is dried. *Crocuses* in flower should in packing be tied up in bunches, with a little damp Moss, and kept, as far as possible, in a growing condition. In the later stages of growth, the new corm rapidly approaches an independent maturity. *Crocuses* dug up after the flower has completely passed away should be packed dry, and before planting, cleaned of the decaying foliage and tunics, also of the remains of the last year's corms. The smallest partially-developed corms, even of the size of a Pea, unless kept too long dry, will vegetate, and soon grow into large, full-sized corms.

It is probable that there are yet many undescribed species to be discovered and introduced. Asia Minor is the metropolis of the genus ; and I would especially point out to travellers the southern part of Asia Minor between Syria and Lycia as being likely to afford new species. The north-eastern extremity of Cyprus, The Taurus, Kurdistan, North-west Persia, and the district east of the Caspian have been little explored, and are likely to afford some new species.

This extract is sufficient to show the style of the work, which is throughout written in a way that a botanist does not repudiate, while it is engaging to the general reader.

The coloured plates show the species fairly well ; they are not meant to be mere pictures of the plants, but we think that in many cases full justice has not been given to the beauty of the flowers in the matter of drawing and colouring. One could wish that other important classes of plants could find monographers of Mr. Maw's stamp.

W. G.

BRITISH ORCHIDS.*

MR. WEBSTER has had much experience in the growing of terrestrial Orchids, and many will thank him for giving them the benefit of it in this neatly printed and handy little volume. He writes pleasantly and with commendable enthusiasm, and has evidently studied the plants which he has grown, so that the book is by no means a mere compilation. We are sorry to learn that the interesting *Spiranthes Romanzoviana*, which has more than once been discussed in these columns, is known in Ireland by the name of *S. hiberniana*, and trust our friends across the Channel are unjustly credited with a name which has neither authority nor grammar to commend it, they will, in any case, resent the styling of the plant as "British" on the faith of its Irish habitat. The variations of *Orchis Morio* seem to demand more praise than Mr. Webster bestows upon them, and he is evidently unacquainted with the beautiful forms of *O. incarnata* which adorn the Southport sandhills ; indeed, he does not appear to know *O. incarnata*, the name of which appears only incidentally as a synonym of *O. latifolia*. We do not accept his new etymology of *Morio*, which is hardly borne out by the evidence of our earlier authors. Much might have been said about the very numerous popular names of the commoner species. Perhaps this, and a description of *O. incarnata* will appear in a second edition, into which we predict this pleasant little book will soon pass.

B.

ROSE GARDEN.

T. W. GIRDLESTONE.

GROUPING ROSES.

As young folks save the best of their bonbons for a *bonne bouche*, so in the selection of Roses for planting in masses the Tea-scented varieties have been left till last as being the best and most beautiful of all Roses. If they are not the most gorgeous, at least they are the most refined ; if not the most hardy, certainly the best worth protection, and at once the earliest, latest, and most continuous bloomers. Tea Roses planted in a sheltered, sunny position may be had in flower out of doors as early as May, and will scarcely desist until the considerable frosts and rough weather of November enforce a temporary rest. As a class, they are comparatively little subject to mildew, especially when they are grown in the open and red rust does not attack them, so that the plants are seldom without abundant and handsome foliage, while their flowers are desired beyond all others, whether by the exhibitor, the florist, or (most important by far) the fair sex. Of the varieties calculated to make an effective display in the garden, Marie Van Houtte, Hon. Edith Gifford, Anna Ollivier, Madame Lambert, Jean Ducher, and Grace Darling are six of the best worth planting in quantity. A good group of the first-named is a thing of beauty and a joy for ever ; its young growth in the early summer is highly effective, but when

its exquisite pale yellow flowers, margined with peach colour, are in perfection, it is irresistible, and the number and quality of the blooms produced during September and October are hardly inferior to those developed in June and July. There should not be a garden in the country where Marie Van Houtte is not grown in abundance on walls (though in such positions care must be taken to keep the plants free from mildew, to which Tea Roses are far more liable when grown on walls than when grown in the open) for early blooms, and in the open in various aspects for supplying cut flowers as well as for making a display in the garden ; it will thrive on light or heavy soil, and succeeds admirably worked on Brier seedling or cutting stocks. In fact, all the Teas prefer these dwarf Brier stocks, and also may be grown to perfection on lighter, hotter soils than most other Roses, so that they should receive special consideration from those who are inclined to say that their soil is not heavy enough to grow Roses. Hon. Edith Gifford is a comparatively recent Rose, having been introduced by Guillot in 1882, but it has already deservedly taken a prominent position. Its white flowers are very freely produced throughout the season, and having a substantial petal, never fails to expand, and for this reason it is one of the best white Teas for growing out of doors. The flowers are also especially ornamental on the plant owing to their being held erect on stiff stems whereby their beauty is fully displayed. Anna Ollivier is a very vigorous and handsome variety and blooms freely ; its flowers vary a good deal, being generally of a pale flesh colour, more or less shaded in the centre with deep coppery rose, but are very attractive in all stages. It is generally considered one of the easiest Teas to grow and flower to perfection, and certainly deserves to be abundantly planted. Madame Lambert is one of the most variable Roses in existence, and there may be often seen at the same time half a dozen blooms so different in colouring as to give the impression that they were distinct varieties. In the first flowering in July the blossoms are mostly of a rosy buff tint, more or less shaded (often very irregularly) with rose, but sometimes with the yellow colour prevailing ; in the autumn, however, the flowers are all of a uniform rose colour, and the yellow shade is but little noticeable away from the base of the petals. This Rose makes a vigorous branching plant, and the freedom with which it flowers in autumn is conspicuous even among such thorough perpetuals as are the majority of the Tea-scented varieties ; so that a good group of it ensures a telling bit of bloom in the Rose garden during September and later. Jean Ducher is a handsome Rose both in plant and flower, growing well and strong, and blooming freely ; its flowers vary also a good deal in colour, from pale to deep tawny yellow, with a darker centre, and are seen to great advantage on the plant, whose sturdy shoots carry them boldly upright. Grace Darling is even younger than the Hon. Edith Gifford, having been sent out by Bennett in 1884 ; but that does not prevent its being one of the most continuous-blooming as well as one of the most exquisitely coloured Roses yet raised. Even in so late a season as that of 1886 proved, this variety was in flower in the open in the third week in June, and in the previous season it bloomed before the middle of the month ; nevertheless it furnished abundant and beautiful blossoms until very late autumn, the individual flowers during September being especially fine. The plant is very free, though not tall, in growth, and every shoot and twig carries a flower, whose colour is a delicious mixture of peach and cream, the petals having a pale base, shaded with rose towards the margin. The complete distinct-

* British Orchids ; containing an exhaustive description of each species, to which is added chapters on structure and other peculiarities, cultivation, fertilisation, classification, and distribution." By A. D. Webster, F.R.S.E. Illustrated. Bangor : Nixon & Jarvis. Pp. 103.

ness of Grace Darling from every other Rose, combined with the extreme freedom with which its flowers are produced, and its exceedingly attractive appearance render it indispensable even where only the very best varieties are grown.

Anyone that planted a good group of each of these six varieties would have, at any rate in the southern part of England, a supply of Rose blooms as long as Roses are obtainable out of doors in this country, namely, almost continuously from June to November, and that in the principal Tea Rose colours, yellow, white, creamy, and rosy tinted. Of course, August in the south is generally a somewhat roseless month; the weather is commonly hot and dry, mildew attacks many plants, and in proportion as the foliage suffers the chance of further bloom is reduced. But what flowers are to be had are pretty sure to be those of the Tea-scented varieties, for the hotter the weather the better they seem to like it, and they are less liable to mildew than most other Roses. Where a larger collection is desired the following varieties are the next best worth growing to make a display in the garden, and complete the pick of each colour throughout the class for the purpose. Among whites, Innocente Pirola is charming, its numerous flowers with their twisted pointed centre being carried erect on stiff stems and being freely produced in autumn, though its petals are less substantial and consequently more liable to be spoiled by wet than those of the Hon. Edith Gifford; and the well-known Niphotos is good where Roses are thoroughly well looked after, but otherwise is hardly vigorous enough. Useful yellows are Caroline Kuster, commonly classed as a Noisette, very vigorous and free, and especially good in a hot season; Perle des Jardins, deep yellow flowers produced on strong, erect shoots; and, in some localities, Etoile de Lyon, a clear pale yellow, whose very full flowers, according to some growers, do not open readily out of doors; this, however, is not the case everywhere, and though the variety cannot be unreservedly recommended, it has in a good many places during the last three seasons proved a valuable addition to the yellow Roses. The two last named Teas may claim to rank as ornamental plants independently of their flowers, from the deep red colour of their shoots and foliage, especially in the earlier stages of growth, though there is always a red-brown tint about a group of these plants throughout the season. Of tinted whites there are Rubens, a fine flower, but the leaves not very large and set rather wide apart, so that the plant is not very furnishing; Souvenir de Paul Neyron, dwarf, but stiff-stemmed, and very pretty; and the recent and charming Madame de Watteville (Guillot, 1883), very free-flowering, the blooms white, delicately washed with pale rose externally. The peerless Catherine Mermets, and the seedling from it, Jules Finger, are two of the best pale rose colours, the latter rather deeper and more bronzy in tint than its parent, and of a more open shape. For a red Tea it was until lately necessary to quote Duchess of Edinburgh, a very charming and floriferous variety, but in reality only a bright rose colour, and almost a China; but in Souvenir de Thérèse Levet (Levet, 1882) there now exists a true crimson Tea that carries its dark red colour well, and is quite without any lilac tint, unless when very poorly grown; its flowers are freely produced early and late, are well displayed on stiff stems, and make in a good sized group a striking and distinctive effect. No name has yet been invented for the combination of rose and apricot, in which the loveliest of all Teas decks her flowers, and though Comtesse de Nadaillac is not a strong grower, she is so beautiful that success in her

cultivation amply repays all the care and pains that may have been bestowed. Who that has ever seen the marvellous boxes of blooms of this Rose that Mr. Prince, of Oxford, so frequently exhibits has not promptly determined to have such flowers in his own garden? Nor will anyone fail to do so that is really a devoted admirer. Her ladyship is an exacting mistress, and demands considerable indulgence at the hands of her lover, but she is gracious to the faithful swain, and though like many another fair dame, she takes but little heed of what people may expect of her, nevertheless, gentle persuasion rarely fails to induce her to grace the rosery with her unrivalled beauty. Princess of Wales is another variety of similar type, but the flowers lack the glowing flush of colour in the centre, though they are freely produced and attractive.

All the Tea Roses so far mentioned, in addition to being those best calculated to make an effective display in the garden, are among the varieties whose blooms are most frequently seen exhibited in winning stands at all the leading Rose shows; but there are a few others whose flowers are not full enough to endure a long journey, or are not large enough to be of use to the exhibitor, but which are very pretty in the garden. Such an one is Madame Joseph Schwartz, a healthy, vigorous plant, which produces large trusses of pretty cup-shaped white flowers, tinted with rose on the margin, and boldly displayed. Another pretty variety, though not showing its flowers off quite so advantageously on the plant as the last-named, is the popular Noisette Narcisse, of which a good-sized group makes a pleasing effect. Madame Falcot and Safrano are too well known to more than mention; but red Safrano, which is distinct and delightful in colour, deserves to be more often seen. Another bud Rose of striking tint is Ma Capucine, said to be a seedling from the climbing Noisette Ophirie, and one which ought to be generally cultivated. Its nasturtium-coloured flowers are attractive in any stage on the plant, but in the bud state, for button-holes and bouquets, they are unique. The same remark applies to Madame Chedane Guinoisseau, whose long, clear, yellow buds among the semi-double expanded flowers make a charming effect on a large group of plants. There is one other of these bud Roses that never seems to have found its way into the English nurserymen's catalogues, called Madame Perny, a vigorous grower, producing abundance of very perfectly formed orange-yellow buds. On expanding the flowers become quite white, and are seen to consist of but few petals, though these are very large, and give the appearance of a bush with great white butterflies settling upon it. The great popularity of individual plants of this Rose when seen growing and in flower is strong evidence of the fact that a plant is not necessarily less effective nor less admired because it has only semi-double flowers, and raisers might be urged to let the public see and say for itself whether it does not like some of the less formal forms among their seedlings, which are so liable to be ruthlessly destroyed for not attaining to an arbitrary standard of formality.

In selecting Roses for grouping, the main point that has been kept in view is the effective nature of the display made in the garden by any given variety when in bloom, and consequently all varieties with pendulous flowers have been omitted, as, except in the case of climbers, the beauty of such flowers cannot be fully seen on the plant. Of course, in a selection intended to comprise all the most beautiful Roses considered merely as individual blossoms, some of these varieties would have to be included; but the general proposition may be allowed to stand,

that a great need in many gardens and not a few roseries is more plants and fewer varieties—not actually fewer varieties, but fewer in proportion to the number of plants grown. If there be room for five thousand plants, by all means let there be several hundred varieties, but if there be room for only a hundred plants, do not let there be anything like a hundred varieties; a tithe of that number would be preferable. If people want to plant six dozen Roses, let them eschew the fatal seventy-two distinct, and rather plant six each of a dozen carefully chosen varieties, or, better still, a dozen each of six varieties.

The accusation has of late years been formulated that the Rose is not ornamental as a garden plant, and this has arisen chiefly from two causes—first, the cultivation of many varieties not sufficiently free-flowering or not good in colour; secondly, the indiscriminate planting of them in ones and twos, here a tall one and there a short one, here a good one and there a bad one, so that there is a worrying spottiness of effect instead of a striking mass of colour. There is little doubt, however, that the charge may be disposed of, if only free-blooming, pure coloured, and, as far as possible, thoroughly autumnal varieties be grown, and that not each represented by a solitary example, but planted boldly in considerable groups.

ROSE GROWING IN AMERICA.

SUMMIT is some eighteen miles from New York, and is a beautiful, hilly, well-wooded place, fast filling up with handsome residences. As a Rose-growing depot it is famous throughout the country and in its neighbourhood, and at Madison, some four miles distant, are located many of the leading cut-flower growers who supply the New York market. Among Rose growers is Mr. De Forest, who has one of the largest greenhouse establishments in the country, and Mrs. De Forest is just as much interested in all that pertains to flowers as is her husband. His greenhouses consist of many ranges of three-quarter span houses 20 ft. wide by 200 ft. long; also some 12-ft. wide and 6-ft. wide propagating houses, but nearly all run about the same in length. They are wooden houses, built of the best material and glazed with first quality French double thick glass. I use second quality double thick French glass and think I am doing well, for it is clear, fine glass; but Mr. De Forest believes that the first quality is more than worth the extra cost. He has resolved not to build any more houses of wood, and is now clearing ground for iron structures. In the Rose houses the beds are not made upon the ground, but in all cases are raised above it on plank benches. There are two sets of greenhouses, a few hundred yards apart; one is heated by steam, and the other by hot water. Mr. De Forest greatly prefers the steam heaters; they are very efficient, quick to act, easy to regulate, easy to stoke, and so far as fuel is concerned very economical—eight tons of coal in the steam heaters giving the same results as fourteen tons in the hot-water apparatus. The steam heat has no injurious effect whatever upon the plants.

THE ROSES GROWN are Bon Silene, La France, Niphotos, Catherine Mermets, white Catherine Mermets, Bennett, and American Beauty; also, but in more limited numbers, Captain Christy, Her Majesty, Paul Neyron, Magna Charta, Mme. Gabriel Luizet, Jacqueminot, and a few other Hybrid Perpetuals. All the Teas are now in fine growth and flower, but of the Hybrid Perpetuals some are being started, while others are not yet "shut up." Bon Silene, La France, and Niphotos occupy the back and front benches, which are raised to pretty near the glass, and are planted out and kept tied down. Niphotos is not upon its own roots. Mermets comprise the majority of the stock grown, and are beautiful. They occupy the central beds, and are in most cases planted out, but one house is largely filled with them in pots. The majority are one-year-old plants, but one house is nearly filled with two-year-olds. One-year-old plants are said to yield the largest crops, but two-

year-olds the finest blooms. A cane stake is applied to each plant. The white *Mermet* is in every way, except in colour, the exact counterpart of its parent. It originated with Mr. De Forest, who considers it distinct from the white variety obtained about the same time by Mr. Taplin, of Maywood. Bennett is growing and flowering freely planted out on the front middle benches. But the *American Beauty* is truly a beauty. Planted out in the middle benches, in fine luxuriance of wood and foliage, and with one bud terminating each shoot, it does not stop till it has nearly reached the glass. Its large size, deep rose-red colour, and delicious fragrance, also the long, leafy stem that may be cut to each Rose, add much to its value. Mr. De Forest says that so far he has not succeeded well with *Her Majesty*, but he is now satisfied from observation elsewhere that he has found out the cause of its backwardness with him, and that is, that it needs a lighter and more porous soil than he generally uses for his Roses. *Mme. Gabriel Luizet* is his great favourite, and he has recently imported it largely. *Paul Neyron* and *Magna Charta* are grown for March flowers. Their immense size always commands attention. *Jacqeminot* for colour stands unrivalled. Mr. De Forest is very fond of *Captain Christy*, and grows a lot of it because he himself likes the Rose, and not for market, as it is too small for that purpose.

The soil used is from rotten turf. In the neighbourhood is an old Apple orchard that had been in Grass for many years, from which he bought the turf. He turned over the top, carted it home, and made a pile of it, putting a layer of team and one of manure alternately, but about twice as much loam as manure. This was done in the autumn, and it will be allowed to remain in the heap till next May, when it will be turned over and used for the bench-beds. Clean cow manure alone is used for manure. All the beds and pots are mulched about 1 inch or 2 inches thick with it. There are large tanks of liquid manure in the greenhouses, and steam pipes run through them to warm the water. It is applied by steam-pump power. Mr. De Forest believes in limited, rather than a liberal, use of liquid manure, and not at all till the roots have first pretty well exhausted the soil.

Mr. De Forest apprehends a great future for Orchid flowers and has resolved to supply the market. He now has, I should think, between one and two thousand plants, but this, he assures me, is only the beginning; he intends to fill several houses (and each of his houses is 200 feet long!) with Orchids alone. He does not mean to displace Roses to make room for Orchids, but to add more new greenhouses.—*WILLIAM FALCONER, in American Florist.*

FRUIT GARDEN.

W. COLEMAN.

THE APRICOT AS A CORDON.

THE Apricot is perhaps the most unsatisfactory fruit tree which comes under the gardener's management. Although thousands of trees have been planted annually throughout Britain and the temperate parts of Europe, only occasionally does it happen that large perfect specimens are met with in the best regulated gardens. Cripples are plentiful enough, as every man who has a bit of wall or a gable end to spare plants an Apricot; and so thoroughly plebeian is the tree in its likes and dislikes, that one sometimes sees the poor man's cottage covered with its bright golden fruit, whilst hard by in the duke's garden, the return from one-sided trees does not pay for pruning and training. In the north of England and Scotland where Apricots are quite as late as Peaches, a south wall is generally considered the best, if not the only suitable, site, and so strong is the force of practice—I might say the tide of northern practice to the south—that in warmer parts we frequently find the hottest wall and border devoted to this moisture-loving tree when a west aspect would suit it much better. Be this theory right or wrong, the fact that the rigid

system of training the branches against highly heated walls, and keeping the roots in borders also hot and dry, having proved disappointing, it becomes a question whether the rut, now hundreds of years old, should not be departed from and a fresh path tried. Light sandy or friable loams are considered the best for Apricots, and these should be deep in proportion to their lightness, but the oldest, if not the most handsome, trees I have met with in the counties of Hereford and Worcester are now growing in deep heavy loams on the old red sandstone. The aspect in each instance faces west, and although the roots are heavily mulched, they receive immense quantities of water early in the spring and throughout the summer.

Moorpark and a closely allied variety known as the Peach Apricot are considered the best, especially for dessert, but unfortunately they are most subject to sudden collapse or limb-perishing. Trees in full health one day are found flagging the next, and no power can save the parts affected. Sometimes one-third of a large tree perishes, but more frequently a branch here and another there goes, and although the fruit on the remainder of the tree ripens properly, once begun the disease stalks along, when, unless the owner can put up with unsightly cripples, a year or two sees them consigned to the fire and young ones taking their place. In many gardens until recently the attention given to the Peach was denied the Apricot: the roots in dry, hard borders, left undisturbed for years, having made a rapid descent into the subsoil in search of the moisture they so much needed, soon became deeply embedded in a cold crude stratum calculated to produce canker, mildew, and sudden collapse, whilst the foliage, which evaporates water, quickly languished against south walls whose temperature exceeded that of their native Armenia. Where large trees still exist, the modern remedy is careful lifting and relaying in rather deep, moist, but well drained loam early in the autumn, and although, provided they are well watered and mulched, this may mitigate the evil of limb-perishing, once in the system it does not entirely stop it. Fresh planting consequently is always going on, but instead of training to the fullest extent I have lately tried cordon training, and, judging from the way in which young trees furnish flowering wood, I venture to think the system may answer. Apples, Pears, and all stone fruits do well as cordons. The Apricot succeeds as a pot tree, and this system, which necessitates the constant addition of fresh soil and good mulching to the roots, followed by plentiful supplies of water, may ward off evils which so many growers now complain of. The Apricot being a very early grower, every operation from planting to pruning should take precedence of similar operations in the management of all other fruit trees, and when it is borne in mind that fruit is obtained from well-ripened young shoots as well as spurs, summer pinching should render winter pruning unnecessary.

Apricots this year are looking unusually well, and where the buds last season dropped by thousands, they are now bursting into a sheet of blossom. Sharp morning frosts still cling to us, and protection, as a matter of course, is necessary. This may consist of canvas, frigi domo, or the like, which must be removed by day to let in light and air, otherwise the young growths as well as the flowers will become soft and tender. Many people do not, however, care to incur expense which involves a great deal of daily attention, and to those I would say cope the walls with broad boards, drop down two or three thicknesses of cheap fishing net, keep it away from the trees by the introduction of a few light poles,

and there let it remain until the fruit is set. Meantime, look well to the roots, for, with the exception of a heavy fall of snow, we in this district have not had a day's rain since Christmas. If south borders are well drained they must be dry; therefore, after mulching with something that will prevent the water from running off, hose them until the lowest portion of the soil is thoroughly moistened. It is not well to water when trees are in flower, neither will well-managed borders require it, but, drought being the forerunner of sterility, sufficient to secure brisk root action must be carefully given and more may follow.

GRAFTED AND INARCHED VINES.

AN impression prevails that if we graft or inarch a Vine with a different variety, the character of the scion is eventually materially altered either for the better or worse, according to the nature of the stock. In reality there are not the slightest grounds for this notion, and the sooner it is combated the better: otherwise, many others besides myself may, to a certain extent, be disappointed with the result of their labours to improve the quality of good-looking, but in other respects quite worthless, Grapes. Against the practice of grafting and inarching Vines I have nothing whatever to advance; on the contrary, there is no better or more expeditious method of securing a complete or partial change of varieties without the loss of a crop. More than that need not be anticipated; otherwise, I am altogether wide off the mark, both as regards my own experiments and those carried out in other places of which I have had knowledge. The favourite stocks with most cultivators are the Black Hamburg and Muscat of Alexandria. At the present time we have fourteen grafted or inarched rods, nearly all on the Hamburg stock, and in no one instance has any improvement been effected in the character of the scion. Gros Maroc on the Hamburg stock in both early and late houses is the same good-looking, uncatable Grape it proves to be when growing on its own roots, and it also retains its rank-growing habit. Those who may wish to change a house of Hamburg Grapes into a variety that may better suit the markets doubtless will do well to inarch or graft with Gros Maroc, the latter requiring no more heat to ripen it. For home consumption, however, the less grown of it the better. Gros Colmar on the Hamburg stock is the same noble-looking Grape as on its own roots, taking quite as long to ripen, colouring no better, and also, unfortunately, still retaining its objectionable Ivy-like flavour. We have two capital rods of Mrs. Pince on the Hamburg stock, and though they give plenty of good bunches, it seems impossible to colour the fruit properly. This variety possesses a good constitution, forms stout foliage, and medium-sized, well-ripened rods are secured without much difficulty. It is not so easily set even as the Muscat of Alexandria and Alnwick Seedling, our grafted rods being quite as bad in this respect as those on their own roots. With us it colours fairly well, keeps till March, and later if required, and, on the whole, is the best-flavoured late black Grape in cultivation. In many late vineries fewer Alicante should be grown, these being inarched or grafted with Mrs. Pince, and thus be quickly superseded by a more high-class variety.

Alnwick Seedling on any stock is as vigorous and prolific as it is on its own roots. The bunches can be readily set with the hand—this being drawn over carefully and frequently when the flowers are opening; the berries will swell to a good size and colour perfectly. They can be kept to the end of November, but try them when I will none have yet given satisfaction, the quality being quite second-rate. Madresfield Court develops all its good and all its bad qualities on either the Hamburg or Muscat of Alexandria stock. The same difficulty is experienced in colouring it up to the footstalks, and nothing but special treatment arrests wholesale cracking of

the berries. In an early or comparatively early house a good circulation of air may be accorded it without greatly prejudicing other occupants of the house; this, coupled with dryness at the roots, will check cracking. In a late house where we had a grafted rod neither condition could safely be complied with, and as a consequence the berries cracked badly. When in good condition it is a grand variety, and I very much regret having to replace it in the late house with a more reliable sort. Gros Guillaume on the Hamburgh and Muscat stocks forms capital rods, the wood when cut being as hard as could be wished for, yet it is quite as shy-bearing as it is on its own roots, nor

plenty of heat the berries are not mere bags of sugar and water, as is sometimes asserted, but are fairly firm and crisp, the quality also being passable. Well ripened it will keep until March or later. The most valuable late Grape, however, will be found in Lady Downes, and the wonder is so few are grown. This, again, we have on the Hamburgh stock, and not in the least altered in character thereby. The young rods break as irregularly, are as disappointing as regards the size of the bunches, the bloom as much liable to damp off, and the berries quite as much addicted to scalding as those on their own roots. We never experience any difficulty in effecting an

refreshing. This useful sort ought to be most extensively grafted or inarched on any available stock—whether a white or black variety—during the season near at hand.

White Grapes also call for comment. Buckland Sweetwater will do well on the Hamburgh stock, and well grown and properly coloured, it is of handsome appearance as well as refreshing when eaten. It is an early Grape suitable for growing with the Black Hamburgh, but is certainly inferior as far as quality is concerned. It does not set so well as could be wished, and we find it advisable to fertilise the bunches with Hamburgh pollen. Thinning out should also be done gradually, so as to eventually retain the desired number of fully developed berries.

FOSTER'S SEEDLING is also suitable for growing in a cool house or for forcing, and takes readily to the Hamburgh or any other stock. It is more prolific than Buckland Sweetwater, sets without any assistance, and the bunches are usually of good size and handsome in appearance. It requires plenty of time to colour and abundance of light, but not direct sunshine, to properly develop both the colour and quality. It keeps fairly well, is sweet and juicy, but not rich in flavour. Trebbiano, which we do not at present cultivate, is an easily grown variety, capable of holding its own when planted among Fig and Peach trees, and will do well against a partially shaded back wall. Inarching or grafting on another stock has no effect upon it. In a cool house it ripens fairly well, but grown with Alicantes and other heat-loving sorts it is materially improved in every respect. Calabrian Raisin keeps well, but I have formed a poor opinion of its merits, and would give neither this nor the still more inferior Syrian house room. Golden Queen is one of the most vigorous sorts we have. I intend trying it for a stock on which to graft its near relative Mrs. Pearson, not, however, with the idea of improving the latter in any way. Golden Queen, unless grown and ripened in a high temperature, is a most worthless sort, nor to my knowledge has either the Hamburgh or Muscat stock improved it. Our best bunches were produced from spurs, vigorous young rods giving disappointingly small examples. Mrs. Pearson is less robust, quite as prolific, and requires less heat to bring it to perfection. It is not often seen in good condition, but with us it colours and keeps well. The flavour more nearly approaches that of Ferdinand de Lesseps, which in its turn more resembles the Strawberry Grape than it does the Muscat, and in addition it has the aroma peculiar to the former. I can recommend this variety for grafting or inarching on any Vine in a late house that can be spared. Muscat of Alexandria, the last to be alluded to, is perhaps the most valuable variety in cultivation, and given plenty of this from July to the end of March, no other white Grape is required. According to my experience, its character is not in the least changed by its being inarched or grafted on to any kind of stock, and those who intend to follow the excellent advice recently given in the pages of THE GARDEN should experiment largely with the Muscat of Alexandria. It is essentially a heat-loving Grape, and although it is occasionally seen in a presentable condition under cool treatment, this is quite an exceptional case.

In connection with this subject, I may briefly describe an experiment that we are trying here. In order to utilise to its fullest extent a house of Muscat of Alexandria during the process of renovation, a strong Black Hamburgh rod was brought through from an adjoining house and disposed along the front. It was intended as a stock for the Muscat of Alexandria, and also to afford an early supply of black Grapes. So well has the rod succeeded in this position, affording as it annually does several handsome bunches, that we have hesitated to wholly change its character. Two rods of Muscats only are established on it—one, by the process known as bottle-grafting, and the other by inarching, these being trained up the roof or at right angles with the stock. Now,

The Monastery of Sumla, Stauros, near Trebizond, close to which is the native habitat of *Crocus vallicola*. (See p. 205.)

is it improved in any other respect. This variety, though not remarkable for its quality, produces noble bunches, the berries being of good size, colour, and they keep well. It is crisp and refreshing, and that is all that can be said in its favour.

Alicante, of which we had at one time several grafted rods, really seems to do better on its own roots than it does on any kind of stock we have tried. It is a sure cropper, the bunches being usually of good size and form; they set freely, too freely in fact, and badly coloured examples are the exception. It is one of the most easily grown and most handsome sorts in cultivation. Given

even break on the older rods, and invariably obtain better bunches from pruned laterals, in these respects differing completely from the Alicante, which is best grown on the long rod system. Lady Downes should be slightly shaded directly there are signs of scalding, this, in my opinion, being the best preventive. With us bunches on end rods are the most liable to scald, Muscats as well as Lady Downes being addicted to it in these positions, whether east or west. A thin shading of limewash checks it at once. Lady Downes usually colours well, keeps till May in a dry, cool room, and is remarkably crisp and re-

if the stock influenced the scion, the latter would naturally start into active growth coincident with the former. Unfortunately, this does not happen, and each season the Muscat is much the later, probably fully a fortnight, in starting, and the consequence is it loses in the race. The Hamburg seems to absorb the greater portion of the stored-up sap, and not till the roots begin to afford a supply do the laterals strengthen. The bunches naturally suffer at the commencement, but if smaller than wished for, the berries attain a good size and ripen well. At the bottom of each rod there are two or three Hamburg spurs, and these are at the present time considerably ahead of the Muscat portion. The same thing happens whether the rods are trained in the same direction as the Hamburg rod or up the roof, where they are eventually returned. Gros Guillaume also worked on the Hamburg stock, and brought through into the Muscat house by way of an experiment, although subjected to a higher temperature and earlier than the Hamburg rod connected with it, is yet much behind the latter, this affording yet another proof that the stock merely supports, but does not otherwise influence, the character of the variety attached to it.

W. LEGGOLDEN.

MULCHING FRUIT TREES.

As planting is now considerably on the increase and root-pruning has been reduced to an annual system in every well-managed fruit garden and orchard, the work is only half accomplished where mulching is neglected. When fruit trees are planted on well-prepared ground early in the autumn, the first operation is staking and watering; then arises the question, is it wise to mulch? In some few instances where the ground lies low and cold it may be advantageously delayed until the sun has lost its power, as solar warmth, be it never so slight, favours the formation of new root-lets; but once this influence has passed away, a covering of some kind should be applied to the surface for the two-fold purpose of keeping in warmth and shielding the roots from the chilling effect of snow-water and severe frost.

LATE-PLANTED TREES, unless the ground is exceptionally dry, do not require watering home, as the soil generally contains and retains moisture in sufficient quantity to serve through the winter, but mulching, as a rule, should immediately follow. Therefore, whilst guarding against keeping the newly disturbed roots in a saturated state, a good covering is a potent factor in the maintenance of an even temperature and securing a good start in the spring. Stimulating manures for this class of mulching are too often and not unfrequently detrimentally used, as it must be borne in mind that the roots of the trees are not in a condition to benefit by the rich substances which are washed down by the rain through the winter. On the other hand, soil of a rich or retentive nature is apt to become sour and unfavourable to the formation of feeders, which seem to multiply in proportion to the difficulty they have to encounter in obtaining food. The best material under these conditions is rather long stable litter, or other substances which will protect without stimulating, and these from time to time may be renewed as circumstances may dictate. As time goes on and trees attain a fruit-bearing condition, their harder, both as regards quantity and quality, must be improved, for it is a well-known fact that rich food not only nourishes the fruit and enables the trees at the same time to make wood and fruit buds, but it also keeps the roots at home near the surface, when otherwise they would descend into the subsoil in search of moisture. Trees in a fruiting state that have been root-pruned are in a somewhat different position, as it generally happens that the check upon vital force favours fertility, and when thickly set with blossom-buds every flower sets for fruit. These, then, be they ordinary orchard or choice wall trees, should be heavily mulched with good rotten manure so soon as the operation of root-pruning is complete, and the better to fit them

for the strain, which in a few weeks hence they will feel, no time should be lost in giving them an additional supply.

CHOICE TRAINED TREES, especially against south and west walls, derive great benefit from mulches, which may be divided into protecting, feeding, and retarding mulches. In many gardens people often incur immense expense—not always necessary—in excavating, concreting, and rubble-draining for their fruit trees, and when all is finished they never allow the roots to reach even the rubble, much more the drainage; for whilst following in the footsteps of their forefathers in the preparation of the borders, they turn into the modern path of root-lifting and relaying in a horizontal position within a few inches of the surface. I do not for a moment condemn this careful preparation: in many gardens it is absolutely essential to success; in others it represents money, which might better be expended in mulching. Take as an instance a newly planted Peach wall: if the trees are to succeed, the roots must be kept within the bounds of solar influence. Water in abundance is used for washing home the soil, but, owing to the porous and drawing nature of the drainage, a state of saturation soon gives way to dryness, when the first set of new roots naturally tend downwards. As this is just what we do not wish to take place, a good protective mulch, which will prevent moisture from escaping and frost from penetrating, is resorted to. Sound, healthy growth the first year being the object, this non-feeding mulch from time to time is replenished, well hoed through the summer, and roots in the autumn are found foraging on the surface. If straw, a bad conductor of heat, has been used, a portion of this is removed to let in the sun, for roots as well as shoots must be ripened. From extension-trained trees we expect fruit the second year, and lime being necessary to all stone fruits, we rake off the remainder of the mulching when the leaves fall, and replace it with an inch or two of old rubble or plaster. The borders, composed of good loam, are more likely to be too rich than poor; therefore, whilst taking a moderate crop of fruit and hastening the covering of the wall with fertile shoots the reverse of gross, the protective mulch is again resorted to. This, combined with plenty of water, supports the crop to maturity, and as soon as the Peaches are gathered every bit of old litter is cleared away as a preliminary to root-lifting. This operation, so often described, is then performed, when the roots, shortened back and relaid near the surface, being rather more than counterbalanced by a large breadth of fruit-bearing wood and foliage fully exposed to the sun, the stimulating mulch comes into requisition, not immediately after the roots are relaid, a second application of lime rubble being sufficient for the winter, but shortly after the crop is set and commences swelling. From this age of the trees forward the stimulating mulch is placed over the roots in the spring and reduced in the autumn when the times arrives for ripening the wood. In the best managed gardens, be the selection never so well made, Peaches and Nectarines will come in with a rush, and the better to prolong the supply, growers resort to shading through the hottest part of the day. Shading cannot, however, be indulged in to any great extent, as anything that obstructs sun-heat and light detracts from colour and flavour; but when a non-conducting mulch of long litter or straw is laid upon the 4-foot pathway, the roots can be kept cool and moist, when otherwise the soil would become parched and heated.

Passing from the hardy fruit garden to the vinery, containing Grapes which we wish to keep fresh and plump for a considerable time after they are ripe, slight shade keeps down the temperature of the house, but the main factor is the retarding mulch placed over the borders after they have received their last watering. Manure, or the advocates of manure, in this department, if anywhere, have much to answer for, as there exists but little doubt that the abuse of this valuable article has poisoned many a border, and, as a

natural consequence, brought about wholesale shanking. Still, manure, like all other matter, is invaluable when judiciously used; but this can hardly be said of it when it is carted steaming and dripping direct from the yard to the early border; when it is dug in spit deep, as I once saw a man with a spade burying it in a Muscat border; or, when in a decomposed state, it is laid on the surface to an extent that will keep the roots in Russia while the foliage is enjoying the climate of India. By all means let us have manure, and plenty of it; but if we are to gain the greatest good from its application as a mulch, we must make ourselves thoroughly acquainted with the condition and requirements of our trees, and use it accordingly.

W. C.

FRUIT TREES FOR COTTAGE GARDENS.

IN the majority of cottage gardens, fruit trees are, unfortunately, conspicuous by their absence. What therefore to plant in them that shall be remunerative is the first consideration. So far as the profitable cultivation of the Grape Vine out of doors is concerned, the question has been answered so emphatically in the negative, that the Grape may be put on one side; and in the case of the cottager, the Peach and Nectarine may be also dismissed. The fruits which I would recommend are the Apricot, Plum, Morello Cherry, Currant, and Gooseberry. I have seen Apricots do capitally on cottage walls, both on east and west aspects; the fruit, too, sold readily at a fair price, and all that were not sold came in well for tarts and preserves. Of course, in districts where the Apricot is a failure generally, it would be folly to attempt its culture. But, on the other hand, where it does well if largely planted, one or two trees on south, east, or west aspects would prove both useful and profitable. It should be remembered that, in all cases where the soil is dry and light, a little artificial treatment is necessary for the Apricot at planting time. A good proportion of well-rotted cow manure should be incorporated with the soil, and a firm surface maintained for at least a yard round the tree. Two of the most useful Plums that will always furnish materials for the preserving-pan, if they cannot be otherwise disposed of, are Rivers's Prolific and Denver's Victoria, both of capital constitution and great and constant bearers. They are most at home on a S.E. or S.W. aspect. For any portion of wall that is immediately at the back of these aspects, the Morello Cherry and Currants and Gooseberries may be used. In fact, walls covered with the two latter are profitable under any circumstances; for the fruit under these conditions is large and clean, and can be quickly and easily netted. Raby Castle and Warner's Grape in Currants, and Warrington, Keen's Seedling, and Crown Bob in Gooseberries, are useful sorts, and cuttings of these inserted in spring will quickly grow into nice plants, and soon furnish a wall. Where there is no spouting or overhanging coping, a tarred board 1 foot in width, fastened near the top so as to throw the water well away from the root, will be found advisable, as a constant drip will make the best soil sour and bad, and this coming close to the collar of the plant is by no means beneficial. All walls up to 6 feet or 8 feet in height can be thus covered with bush fruits, but when the height exceeds this the Morello Cherry can be substituted. This is too well known to require any recommendation; it might be planted more frequently than it is both by amateurs and cottagers on all N.E. and N.W. aspects where there is space for a tree, as, if not required for home consumption, there should not be the slightest difficulty in finding a market for the fruit.

E. B.

Watering Strawberries in pots.—A low temperature in winter before forcing begins is beneficial to Strawberries, as under such conditions their rest is more perfect. But dryness at the root, if it leads to the injury of the young fibres lying close to the sides of the pot, has a bad effect upon the future crop. The best way to keep Strawberries which are intended for forcing, is the old-fashioned one of plunging the pots up to the rim in coal ashes in turf pits. There is always moisture enough in the ashes to keep the roots plump. Plants unplunged in cold pots at this

season if not looked over sometimes and watered, may easily sustain injury, owing to dryness of the best roots, which are those lying close to the sides of the pots, and if these receive any check, the crop cannot be so good as it otherwise would have been. Very often when the flowers are imperfect, or do not set properly, or the young fruit later on turns rusty, the cause might be traced (*i.e.*, if all things could be traced to their sources) to dryness at the roots sometimes before the plants were moved into the forcing house. During the drying winds of March, if the plants in cold pits or elsewhere waiting to take their place in the forcing house become dust-dry, they must suffer.—E. H.

SEASONABLE WORK AMONG FRUITS.

Figs.

THE fruit on early started pot trees will now be swelling fast if it has not reached the flowering stage. For several weeks there will be no apparent progress, but this sudden stand need not cause uneasiness, neither must it prompt to hard forcing, as no amount of fire-heat will induce them to move until this process is complete. The trees must, however, have plenty of water, the syringe may be plied twice a day, and the temperature if possible must be kept steady within the range of 60° to 65° by night and 70° to 75° by day. In due course the most forward Figs will commence the last swelling, and as this will carry them quickly to maturity, a little more heat, especially by day, more air, and plenty of good diluted liquid will be found highly beneficial. Large established trees in well crooked pots cannot easily be over-watered, always provided the stimulants are not used too strong, and the bottom-heat is kept at 70° to 75°, but once allow them to flag, or even feel the want of this element, and the chances of the fruit standing will be considerably reduced. Top-dressing next to water is a potent factor, and should be renewed as often as it is washed in and the roots show upon the surface. Many people use rich rotten manure as a mulch for all fruit trees in pots, and Figs above all others will stand it, but for these even I always give preference to rich turf from which the small particles have been beaten, placed in good large pieces on the surface and hanging over the rims of the pots. If this is not strong enough, bone dust and warm liquid will soon be the means of converting the turf into a wig of roots resembling a door-mat, and as these will strive to escape their bondage, no harm, but much good, will follow their creeping into the plunging material. Once this is fastened upon all danger of dropping will be at an end, and the flavour of the fruit will be richer than that from trees to which solid manure has been supplied. Light and air being so essential to colour and quality, ventilation whenever the temperature touches 70° must be attended to; then, as the sun gains power, with more air, the house may rise to 80°, and 5° higher after closing. At this time, not later than 3 p.m., the syringe must be most vigorously plied, not only over the foliage, but also over the bed, the walls, and well into dry corners, for there, if anywhere, will insect pests put in an appearance, and once started they spread rapidly.

Succession houses in which the trees are planted out and trained on trellises should now be well advanced. If well thinned out at the winter dressing and ample room can be found, train all leading shoots forward, as every leaf should be furnished at the base with a fruit, and allow them to extend until they reach the extremity. Then pinch and thin out weakly growths which have started from the points of the old wood to prevent the trellis from becoming crowded. Look well to the borders, and as the roots appear give them frequent supplies of light rich turf and lime rubble. The great difficulty to be overcome in the management of these border-trees is grossness. Manure produces and fosters this; therefore through the early stages it should be used with care or dispensed with. Later on, when they begin to feel the strain of the crop, a good cover-

ing of previously fermented stable manure will be found beneficial, but then even it should not be overdone, as fresh turf, bone-dust, and diluted liquid act quickly, and produce short-jointed healthy growths, which insects do not care to interfere with. The syringe in all Fig houses of course plays a very important part, and here at least twice a day the refreshing shower will form a part of the daily routine. The temperature may range from 60° through the night to 75° by day, but the Fig being such a heat-loving subject, a few degrees higher by day will do no harm where time is an object.

Late houses.—If trees trained against walls in late houses or cases are still partially covered and resting, all protecting material must now be cleared away, as the point buds will soon be moving. As more than one crop can hardly be expected, pinching, it must be understood, will not form a prominent part of their treatment. Therefore, the principal fruit to ripen being already formed near the points of the past year's wood, as many of these spurlike pieces as will furnish the wall or trellis must be retained, whilst those not wanted must be pruned back to a dormant eye to furnish a relay of wood for another year. Some few of these summer shoots may bear fruit if the autumn is fine, but provided they are allowed to extend, they will be thickly studded with embryo Figs near the points, when those behind which have become larger than Peas may be rubbed off to save them from falling. Treated in this way, every variety of Fig met with in our gardens will ripen one crop without the aid of fire heat, but, if practicable, a flow and return pipe should be introduced if only to ripen up the wood and late shows in the autumn. If these trees were root-lifted and relaid in rather poor, but free, compost in the autumn, a liberal mulch should be placed over the balls and repeatedly watered until every particle is properly moistened. In this department, as I lately pointed out, the roots having been checked, a stimulating mulch will be necessary.

THE ORCHARD HOUSE.

Shortening back where pruning was deferred and disbudding in the earliest houses will now require attention. Trees which have set heavy crops of fruit must also receive timely relief by the removal of the least promising, as nothing can be gained by taxing them with more than a moderate percentage of the best for the final thinning. In all cases those intended to ripen should occupy the upper sides of the shoots, the nearer home the better; and, provided a good shoot is starting from the base and another from the point, all intermediate growths, especially where there is fruit, may be pinched back to two or three leaves for the present. Ultimately many of these will be removed, but for some time to come the few leaves left will foster root action and feed the fruit.

Water, of which pot trees, unless deeply plunged, will now take liberal supplies, may be tinged with stimulants of some kind; and soot-water once or twice a week through the syringe will have an excellent effect upon the fruit and foliage. On other days pure, soft water quite up to the mean of the house will be found most suitable, and this must be plied rather sharply to the undersides of the leaves, also to the stems and walls of the house, the first time when the temperature begins to rise: the second, when the ventilators are closed in the afternoon. The last syringing, be it understood, should always be performed in time for the leaves to get fairly dry before nightfall; and as progress is made under the influence of the afternoon bath, fire-heat on bright days should be shut off, to admit of early closing.

Temperature.—As days increase in length and more sunshine may be expected, a sudden rise of temperature must be guarded against by giving a little air early, and increasing it by degrees until the maximum is reached, when reducing and final closing must be performed in a similar way. As Peaches at this stage are impatient of strong heat, it will be well to err on the safe side for the present by maintaining a rather low night tempera-

ture of 55° to 58° when the weather is mild, a few degrees lower when cold, and about 10° higher by day. When fire-heat can be shut off and the sun is bright, a higher range will do no harm, as top and bottom air in proportion will be admitted. These figures, upon the give-and-take principle, will apply until after the fruit is stoned, when an increase may take place, but unless time is an object, 60° by night, always with a chink of air, should not be exceeded.

Top dressing, as soon as the fruit is thinned, must be applied to the tops of the pots. Every man has his own favourite compost, and, depending as the quality of the crop does upon this, the first care should be the preparation of sweet, sound materials that will not injure the roots; the second, their application, little and often, as feeders show upon the surface. Good rotten manure alone produces vigorous shoots and foliage, but the fruit requires plenty of lime; and the better to secure this, bone-dust and old lime rubble added to stiff calcareous loam make the best top-dressing I have yet met with.

Succession or general orchard house.—In this a mixed collection of trees is generally met with. Cherries and Plums are first in flower, then follow Peaches and Nectarines, which, as a rule, form the most valuable part of the crop. If Strawberries were started on the floor as suggested some time ago they must now be placed on the shelves, where they will have the full benefit of light and air, and the danger of the foliage becoming drawn will be reduced to a minimum. Steady supplies of water in a tepid state must be given by an experienced person, as quantities that will keep the soil in a state of constant saturation, next to the want of this element, may lead to mischief. The best time to water the trees is early morning, as one can then best judge of their requirements, but when the season gets further advanced and the foliage is fully developed the watering of all that have become dry through the day should precede the afternoon syringing. The syringe, of course, plays a very important part in the development of the flower-buds, but bearing in mind that fire-heat, never very strong, is often dispensed with for days together, a sloppy state of the house, especially towards nightfall, should be strictly avoided. Forcing with a constant circulation of air is also another cardinal point which many overlook. When fresh air is treated as an enemy and the house is kept at the proper temperature with closed ventilators, a little time at the outset may be gained, but the flowers are never so bold, neither do they set so well as when this element is freely admitted. Draughts at all times must and can be avoided, for when the wind is strong enough and sufficiently keen to produce a draught, the house must be very compact indeed if a circulation with closed ventilators is not steadily going on. Although orchard-house fruits, Strawberries especially, are open to attacks of spider and greenfly, the first does not often put in an early appearance, but the second springs into life as if by magic, ready to pounce upon the flowers as soon as they are open. As fumigating is quite as injurious as the enemy, two smokings at least should precede the flowering stage, otherwise the most promising trees will certainly be attacked and most likely ruined for the season.

THE CHERRY HOUSE.

The most beautiful sight in a forcing garden is a house of Cherries in full flower. They require very little forcing, but, like the preceding, must be kept free from aphid; they must be well syringed, and although they require a low temperature, a free circulation of air is imperative. On mild nights and bright sunny days they can be brought on without the aid of fire-heat, but when they come into flower a gentle circulation through the hot-water pipes favours the admission of more air, which, rendered light and buoyant, carries off superfluous moisture, when otherwise it would condense upon the petals and prevent fertilisation. When Cherries are in full flower they require daily attention with the camel's hair

brush, and almost before the fruit is set another enemy appears upon the scene. This is the minute grub, which sometimes devastates whole walls of open-air Cherries, and although under glass, it is greatly checked by thorough cleansing; in the best managed houses it is more or less met with. If left alone it soon pierces every fruit, insecticides are thrown away upon it, and the only remedy is catching and killing. Its destructive age fortunately is short, but during that brief period daily examination of the neatly rolled-up leaves must not be neglected.

The temperature of the Cherry house, I ought to say, should range from 40° to 45° on cold nights, from 50° to 55° by day, and a few degrees higher when solar heat favours free ventilation.

PLUMS.

Although these are often forced up to the flowering stage with Cherries, there comes a time when Plums, which are longer in arriving at maturity, require different treatment. If all the trees of the two kinds are grown in pots, they may be divided at the outset, but the best result is generally achieved by confining them to separate houses, or perhaps the same house with a division in the centre. A flow-and return pipe along the two sides of a span-roofed house of large dimensions is quite sufficient, and these may be continuous without valve or check through the two compartments. If heated separately so much the better, as the Cherry house, first cleared of fruit and trees, can then be devoted to other forcing purposes without hastening the Plums, which, by the way, make very little satisfactory progress under hothouse treatment. The management of the two up to the ripening of the Cherries being in every way identical, details contained in the preceding paper need not be repeated. One remark may not, however, be out of place, and that refers to the selection of varieties. Wherever a second house, or even a mixed orchard house, is at command, none but the best of the early sorts of Plums and Cherries should be taken in for forcing. The cream of the latest varieties will ripen under glass without the aid of fire-heat, but a cold, damp atmosphere being so detrimental to the trees when they are in flower, and again when it is desirable to prolong the season of the ripe fruit, no house must be considered safe or capable of giving full value where a simple heating apparatus is not present to fall back upon.

CHRYSANTHEMUMS.

E. MOLYNEUX.

THESE have become so popular, and are withal so useful, flowering as they do both early and late, that I feel pleased a column or two of THE GARDEN is in future to be specially devoted to them. The method of cultivation which finds most favour now-a-days is that by means of which large blooms are produced; but in the case of such cultivators as are merely wishful to have a houseful of flower from which blooms for indoor decoration can be cut and not missed, bush cultivation may be specially recommended. The plants that are to bloom earliest will now be in what are known as 3-inch pots, and those not already in such pots should be at once placed in them from the cutting pot in which they now are, &c., if fairly well rooted. It is a mistake to allow Chrysanthemums to become pot-bound, as when that happens they do not quickly take when shifted to the new soil, and thus a check is given which should be avoided. The best compost for this shift is two parts fibry loam, one half soil, and one spent Mushroom bed manure, together with a free admixture of sharp silver sand. If the loam is inclined to be heavy, add crushed charcoal freely; this keeps the whole porous. Pass the mixture through a coarse sieve, rubbing the fibrous pieces also through its meshes. Careless operators in potting the plants

sometimes leave vacant spaces between the soil and the pot through using the soil in too rough a state, but when made comparatively fine, as just recommended, this defect in potting cannot occur. The pots should be clean and well drained; place over the hole at the bottom an inverted crock sufficiently large to cover the opening; over this place a few smaller crocks, and over these some of the rougher parts of the soil, potting firmly, *i.e.*, ramming the soil evenly around the ball. Some use dirty pots, but they harm the plants, inasmuch as when shifted the roots get broken, through adhering to the soil that is attached to the sides of the pots. If the soil used is moist, no water will be required for a day or two; but after that they must not be allowed to suffer from want of it; nor must they have too much, as that stagnates and sours the soil.

THE POSITION which they are to occupy is the next consideration, and where there is but little space that is often a puzzle. House room may be economised by having shelves suspended from the rafters, and no more heat should be employed than what will keep out frost. In such a position the plants will flourish much better than when placed upon ordinary stages, which are generally far from the roof; consequently the plants become drawn, a circumstance to be avoided. The shelves in question need only be of a temporary character suspended by means of strong wire screwed to the rafters. They may be about 9 inches wide, more or less, according to circumstances, and on each side there should be a groove to run the water off to one end, which can easily be done by allowing a slight fall in that direction. If a position such as that just described cannot be had, the plants, after being potted, must be accommodated with a cold frame. Many, indeed, prefer this to growing them in a greenhouse, but I do not, as early in the season their growth is more likely to receive a check in frames than in a greenhouse. Where cuttings have not been inserted to produce plants for outdoor planting in herbaceous borders or for the production of late blossoms which are so much prized about Christmas time and during January, no time should be lost in doing so. Where convenient, such cuttings are best struck singly in 3-inch pots, but where such pots cannot be had, three or four cuttings may be placed around the sides of a 3-inch pot. The soil used should be of a sandy character, say half and half loam and leaf-soil, with a free admixture of silver or sharp river sand. On the top place some sand, to be carried down to the bottom of the hole made by the dibber to receive the cutting, as roots are formed more quickly in sand than in soil. Under handlights in a cool house is the best place for them, but, failing that, a spent hotbed, or even a cold frame will do, giving them just sufficient water to prevent them from flagging. They will emit roots readily, and after that more air will be required in order to induce stocky growth.

Chrysanthemum sports.—I think I have noticed an interesting fact about these, which perhaps other growers can corroborate or disprove. It is that the tendency of a plant to sport takes a certain number of years, more or less in different varieties, to develop, and then shows itself all over the country simultaneously. To speak of my own experience, in 1885, the year in which William Robinson, the bull sport from Bouquet Fait, appeared, my plants of Bouquet Fait showed in some instances a tendency towards bull. In 1886 I had the identical sport fully developed. Last year my plants of Ethel showed yellow petals in some flowers, and one flower was so yellow that I might perhaps have obtained the yellow Ethel (Mrs. Jones), which is now being distributed. The year before Lady Selborne, the white James Salter,

was shown I had the same sport in perfection here. This fact, if it be a fact, is not so strange when we remember that the entire existing stock of any one variety is really, in a sense, one and the same plant, and will therefore develop its latent peculiarities everywhere at nearly the same moment.—G. H. E.

GARDEN FLORA.

PLATE 586.

ENGLISH IRISES.*

IRIS XIPHIOIDES (*Xiphion latifolium*).—"The great broad-leaved bulbous Flower-de-luce" of Parkinson has a very limited geographical range, being chiefly confined to the meadows of the Pyrenees, whence it has been called *Iris pyrenaica*. It seems to have acquired the name of English Iris because it, or at least the blue form of it, was introduced to the Dutch gardens by way of England, being probably brought from Bordeaux to Bristol, where Lobelius, according to Parkinson, asserted it grew wild. The sagacious Parkinson, however, concluded that any apparently wild specimens of it in the west of England must have been "escapes."

It is closely allied to the Spanish Iris, *I. Xiphion* (*Xiphion vulgare*), but differs in the outer coats of the bulb being more fibrous and husky, in first "spearing" above ground in spring instead of in late autumn, in the flower being larger and broader in all its parts, differently formed and differently coloured; in the leaves being much broader, and in the capsule being large and swollen with large ovoid seeds, "a three-square head, somewhat long and lanke or loose, containing in it rounded yellowish seeds, which when it is ripe will rattle by the shaking of the winde in the dry huskes." It flowers, too, later than does the Spanish Iris.

All the authentic wild specimens with which I have hitherto met with have been of a blue purple colour, but the many kinds in cultivation, which seem to be varieties arising from seedling sports, bear many colours, ranging through various shades of purple, from very blue-purple to a red-purple, or, as right-hand figure in plate, a red in which hardly any blue is left. There are also forms pure white or nearly pure white, or white with red-purple or blue-purple blotches. The chief of these forms seem to have been known to Parkinson. The yellow hue so common in many varieties of the Spanish Iris is absent in the English Iris, as is also the peculiar bronze tinge so common in the former. Parkinson says he had heard of a yellow broad-leaved bulbous Flower-de-luce, but had not seen it, and evidently did not believe in it.

Some of the flowers of the cultivated forms are very large, and nearly all of them are beautiful, though I must confess that the blotched forms do not commend themselves to my taste, and while I admit that their form is more beautiful than that of the Spanish Iris, with its stiff and rigid lines, and many kinds possess a wonderfully full rich colour, I miss in them the many exquisitely tender hues of the latter.

Spach described under the name *I. spectabilis* a form which he believed to be a hybrid between the Spanish and English Iris, and the kind often spoken of as Thunderbolt has by some been supposed to be this, but I cannot recognise in Thunderbolt any traces of *I. xiphoides*; moreover, it does not answer to Spach's description, nor have I as yet seen any form which I could admit as even a probable hybrid.

* Drawn for THE GARDEN by Mr. Moon in Mr. Ware's nurseries, Tottenham, on July 11, 1886, and printed by G. Severeyns.

ENGLISH IRISES

Like the Spanish Iris, the English Iris likes a rich sandy open soil, but while it desires to be fairly dry in winter it needs much more water in the spring and early summer than does the Spanish Iris. If the early summer be rainless, it is apt, in dry localities, to go blind or flower badly.

Where the drainage is good and the winter rain not excessive, plants will thrive all the better for being left alone for at least three or four years, but in some localities I believe it is found advisable to lift the bulbs frequently. If they must be moved the bulbs should be taken up as soon as the foliage dies down, for if they are left in the ground it will be seen that after the late summer or early autumn rains roots are quickly sent out, though, as I have said, the leaves do not shoot until early spring.

The seed may be sown as soon as ripe in the open in some fine prepared soil; it will almost certainly germinate in the following spring, and the seedlings will flower, according to situation and climate, in three or more years. Such seedlings as I have myself raised merely reproduce the several varieties already known, and I imagine to obtain a new break some fresh blood of some other species must be, if possible, thrown into it. M. FOSTER.

STOVE AND GREENHOUSE.

T. BAINES.

APHELANDRAS.

Few late summer or autumn-flowering plants have a brighter or more cheerful appearance than the old-fashioned *A. cristata*, a plant that at one time was more frequently met with than it is now. Its distinct habit of growth and its dense, erect flower-spikes standing up above the massive drooping, glossy leaves render it a striking object. It blooms freely whilst quite small; a cutting struck in spring and grown on freely through the summer will flower in autumn. Not the least of the merits which this plant possesses is the fact that it is amongst the easiest of all flowering stove subjects to grow. It will also keep in a healthy, thriving state for an indefinite time; in fact, with ordinary care old specimens that have bloomed for a dozen years will be found more effective than younger examples. This, and also most of the other *Aphelandras*, succeed with a moderate amount of heat, and on that account are suited to the requirements of those who may not happen to have a stove. Another advantage belonging to *A. cristata* is, that under ordinary treatment it flowers sufficiently early in autumn to admit of its being placed whilst in bloom in a conservatory where a little warmth is kept up. Thus treated its brilliant orange-red, crested spikes contrast strikingly with anything with which they happen to be associated. In places in which the room that can be devoted to plants that require heat during winter is limited, it becomes a matter of importance to select kinds that will not occupy too much space. Those thus circumstanced will find *A. cristata* just the plant to meet their case, as after flowering it should be cut hard in, and in this way does not require much more room than that which the pots occupy. Amongst other kinds that deserve especial mention are *A. aurantiaca*, a plant that attains a medium size, and produces its bright orange-coloured flowers freely. *A. aurantiaca* Roezli, too, is a beautiful variety, which will flower in a miniature state; little plants of it in small pots consisting of a single shoot not more than 6 inches high produce flowers sufficient to admit, when grown in numbers, of their being dispersed freely about the

stove, where they have a charming effect. *A. Leopoldi* is a stout-habited sort, with broad, massive, shining green leaves. Its flowers, which are yellow, are produced like those of the others in erect spikes. There is a variegated form of this plant, which is like the type in everything except the leaves, which are distinctly marked with creamy white. *A. elegans* is distinct from any of the others just named, and well deserves cultivation. *Aphelandras* are easily propagated; they strike freely from cuttings at almost any time of the year when they can be obtained. Plants that flowered in autumn or during winter, and then had their tops taken off after the bloom was over, will have broken into growth and will soon have shoots in right condition for striking, viz., when about 6 inches long. Treated in the ordinary way in the matter of heat, shade, and moisture, and kept moderately close under a propagating glass, they will root in a few weeks, after which move them singly into 3-inch or 4-inch pots. After trying several kinds of soil, I find they do best in a mixture of half peat and half turfy loam, with a little rotten manure and some sand. There is a natural disposition in *Aphelandras* if left to themselves to spire up with a single stem, showing little inclination to throw out many side branches until they are too tall to look well. With the stronger growing sorts, like *A. cristata*, it will be as well to pinch out the leading shoot when they have made some progress; the effect of this will be to cause the production of a pair of shoots, not more, as in the case of these *Aphelandras*, stopping the leader will not make them push side growths to the extent that occurs with many plants when so treated. But unless the grower is willing to sacrifice the first year's flowers with the object of getting large examples in little time, they must not be stopped a second time the first season. After potting them off keep the plants in a growing temperature with the atmosphere somewhat close for a few weeks; then let them have more air with a little shade when the weather is bright. By midsummer they will require moving into pots two or three sizes larger, continuing to treat them as before all through the summer. They should be syringed freely once a day, for though not particularly subject to the attacks of insects, both thrips and red spider sometimes trouble them if enough water does not reach their heads. In the case of the small-growing kinds, like *A. aurantiaca* Roezli, it is better not to stop the leader, but rather to concentrate all the strength that can be got into it; in this way finer heads of flowers will be forthcoming, neither will this and the other smaller growers require so much room; 5-inch or 6-inch pots will be quite large enough the first year.

When autumn comes give more air and cease shading, but keep up the temperature fairly, as, in common with most other plants that flower during the waning year or in winter, they will not bloom so well if kept too cold. As soon as the plants have done flowering head them down to within about three joints of the collar, or of the point where they were stopped at; after this give less water, only letting them have as much as will keep the soil from getting so dry that all growth would be stopped. During winter a night temperature of about 60° will suffice; here they will break slowly, and be in a condition for moving into larger pots in spring. At the time of shifting get as much of the old soil away as can be done without injuring the roots; when the shoots have made some progress pinch out their points and tie them well out, which will induce them to break back. Treat as in the previous summer generally, giving manure water frequently when the soil gets full of roots.

Managed in this way, and each season after the flowering is over cutting the heads in moderately close, with pot room proportionate to the strength of the plants, and the more or less vigorous habit of the kinds grown, the plants can be kept going for a long time, continuing to produce flowers in proportion with their increase in size.

Nicotiana affinis.—Plants of this kept over from last year will now be coming into flower, and if placed in a conservatory the flowers when open will emit towards evening an agreeable perfume. To grow this well it should be planted out, and for this purpose seeds should be sown now; the young plants when up should be pricked off into pans or boxes, and planted out, about 18 inches apart, in a bed that has been previously well manured. When planted in a shady quarter they partially lose their reputation of remaining closed during the day and opening by night. They grow from 3 feet to 4 feet in height, and will continue to flower until cut down by frosts.—W. H.

Azalea Deutsche Perle.—To anyone requiring a white *Azalea* this can with confidence be recommended, as the blossoms possess such a massive wax-like texture that they last in beauty much longer than most of the others. The blossoms are large, of the purest white, and of a semi-double character. A very marked feature is the graceful way in which the edges of the petals recurve, rendering the whole outline of the flower more pleasing than is the case with stiffer and more formal-looking blooms. It is equally free-flowering as the old favourite kinds, and should, when better known, supersede many of them. With regard to *Azaleas*, it is by no means necessary to purchase grafted specimens, for they are not difficult to strike from cuttings, and little bushes grown in this way may be used for a variety of purposes, for some of which they are better suited than when grafted on a bare stem some few inches high. The cuttings from plants that have been forced strike root better than those that are allowed to flower at their natural season.—H. P.

Cyrtanthus McKeni.—This pretty little bulbous plant was so recently described in THE GARDEN, that no further notice of its general appearance is herein needed, but with respect to its free flowering qualities, and the strong claim it possesses to more extended cultivation, I may mention that a pan of it here containing a score of bulbs has not been without flowers since the commencement of November, and there is yet one good spike upon it with a blossom or two still to open. It has been grown in a greenhouse with no more attention than that given to *Pelargoniums* and similar subjects, the principal care being to keep it fairly dry during the resting season. It increases at a moderately quick rate, so that stock is being continually added to. A compost principally composed of sandy loam is well suited to its requirements, and, like many other bulbs, the less it is disturbed at the roots the better will it flower.—T.

SHORT NOTES.—STOVE AND GREENHOUSE.

Amaryllis formosissima.—This very beautiful variety produces dark scarlet or crimson blooms, which in a cut state are very useful. It is grown largely by Mr. Woodbridge at Syon House.

Pelargonium Niphetos.—This variety is well suited for growing in pots for winter-flowering. It is strong and dwarf in habit, and very free-flowering. The flowers are pure white. Messrs. Hawkins and Bennett prefer it to *McLane* Vaucher.

Latania rubra.—A fine specimen of this handsome Palm, from the Mauritius, may now be seen in the nurseries of Messrs. Hooper, Twickenham. The leaf-stalks are very strong and of a bright red colour. The ribs of the leaves are also red, thus rendering it very effective.

Pelargonium F. V. Raspail.—This is a semi-double variety, the flowers of which are deep scarlet and the individual pips large. The plant itself is dwarf and free-flowering. This and *Wonderful* are the only two double varieties grown by Messrs. Hawkins and Bennett for market.

Hymenocallis macrostephana.—This beautiful plant is now in flower in many collections. It has large leaves measuring over 2 feet long and produces umbels of

large, pure white, sweet-scented blooms, which are very useful for cutting. It is grown largely by Mr. Woodbridge at Syon House.

TREE CARNATIONS.

THE varieties usually included in this section are those that flower freely during the winter months, and although some of the sorts are of a tall habit of growth, many are very dwarf and compact, and it is somewhat difficult to say which do and which do not properly belong to the type; but I believe those with fringe edged flowers are the most typical, and these are invariably tall-growing. However, it is not necessary to be too particular on this point, especially as they are generally grown for supplying cut bloom, though some of the dwarf varieties make very useful pot plants, especially for autumn work. Miss Jolliffe, flesh-pink; Mdlle. Carle, pure white; A. Alegatiere, bright scarlet; Dr. Raymond, deep crimson; Mrs. Llewellyn, rosy pink; and Jean Sisley, yellow ground, flaked with red, are six of the best dwarf sorts, and are also very useful for cutting purposes. Other good sorts for cutting from are, Andalusia, pale yellow, flowers large-fringed, one of the best for winter-flowering; Sir Charles Wilson, bright rosy scarlet, flowers very large; Mrs. Keen, deep crimson, very fine; Lucifer, scarlet; Laura, delicate flesh pink; La Zonane, pink and scarlet striped; Empress of Germany, white, tipped with pink, flowers very large; Rufus, scarlet; Indian Chief, crimson.

CULTURE.—To secure good plants, the pipings should be taken as early in the year as possible, but where fresh young side shoots cannot be obtained, it will be better to stop a few plants and place them in heat for a short time. In taking the pipings it is not desirable to pull them off close to the old stem, as is sometimes recommended, but they may be cut or pulled out a joint or two away from the stem, care being taken that they are not bruised in the operation. The cutting pots should be well drained, and light sandy soil used, the pipings being put in only just deep enough to keep them firm. The best position to root them in is where there is a brisk bottom-heat, and where they can be kept quite close and well shaded; they should, however, have ventilation for a short time every morning to sweeten the atmosphere. They must also be looked through carefully, and if any signs of damping appear, those affected must be removed at once, otherwise it will soon spread and destroy a whole batch. As soon as sufficiently rooted, they should be potted off singly, and if kept close they will soon take root in the new soil, and ventilation should be given freely to induce a sturdy growth. I believe that Tree Carnations are often ruined through being kept too close and warm during the early stages of their growth. Plants that are well exposed will branch out naturally, while if kept close they run up spindly, and even though they may be stopped they never make good bushy plants, which is so essential to secure a succession of bloom. The plants should be potted on as they require it, and as soon as they are well established they may be stood out in the open where they may remain throughout the summer, but should be placed under cover before heavy rains come on in the autumn. To flower them well through the winter it is essential that they should have a light, airy position, and only sufficient fire-heat to keep off damp or frost. E.

Forced Lily of the Valley.—Given good crowns, the forcing of these is a comparatively easy matter. Why so many fail to obtain an extra early supply of flower-spikes is in many cases simply owing to the crowns not being sufficiently well ripened. When the attempt is made with either Dutch clumps or home-grown crowns, failure is almost certain. The well-ripened Viennese crowns give the most satisfaction. Not only will badly-ripened crowns fail to start early, but when thus prematurely placed in a strong heat, this seems to render them totally unable to start at any time later on. The crowns which fail to start

early will remain quite fresh in appearance, but perfectly dormant for twelve months—perhaps longer. A very high temperature is not absolutely necessary to insure an early start, neither our top nor bottom heat being at any time much above 80°. What I hold to be of the greatest importance is that light be perfectly excluded from the crowns. We find no plan to equal plunging the pots deeply in a mild hotbed of leaves, fully 3 inches of this material covering the crowns. They must be withdrawn before the spikes are far advanced, and gradually inured to the light. Afterwards, if stood on a shelf in a house maintained at about 55° to 60°, the spikes will develop slowly and strongly, thus giving time for a few leaves to be formed. The suggestion that old pot plants be started early for affording a supply of leaves is a good one. Lily of the Valley leaves are naturally the best greenery for employing with the flowers, and if a number of last year's forced plants are kept, and well watered as well as fed with liquid manure, many of the crowns will be stout enough to flower. As these forced plants naturally ripen early, they are admirably adapted for forcing in November and December. They can be made to yield a good number of strong spikes of bloom, and the leaves later on will be of great value for using with the spikes obtained from imported crowns or clumps. The Dutch clumps are profitable for flowering late in January and onwards. Early in February they were very useful, and at the present time we have them flowering freely, many of the clumps giving us eighteen good spikes, and a few even a greater number.—W. I. M.

Aphelandra aurantiaca.—Several of the Aphelandras have very bright and showy blooms, but generally the plants are apt to become leggy, and get naked at the bottom before they flower. This may be prevented to a certain extent by late propagation, and thus treated we have had a fine show, especially of *Aphelandra aurantiaca*, at a time when flowering plants are but sparingly represented. The specimens under notice were struck during the latter half of the summer, the points of the stoutest and most promising shoots being chosen for the purpose. After rooting, which does not take long, they were shifted into 5-inch pots and placed near the glass, so that the bottom leaves were retained and the plants kept dwarf. By these means we had specimens not more than 6 inches in height, each carrying a fine head of bloom, and at this size they are useful for many purposes. Perhaps the most effective method of arrangement was that of grouping about a dozen together on the stage, and relieving the brightness of their colouring with green-leaved subjects, as in this way they were rendered more telling than if dotted indiscriminately here and there.—T.

Boronia megastigma.—As far as bright-coloured blooms are concerned, this may be safely regarded as the least showy of all the Boronias, but its delicious fragrance renders it almost invaluable at this season, added to which the elegant habit of the plant and the profusion of its blossoms are both noteworthy features, for though the bell-shaped flowers are on the exterior of a dull, bronzy hue, they are delicately poised on their slender stalks, and when seen in a mass are by no means to be despised. The fragrance is such that a plant or two will serve to scent a good-sized structure, and an additional recommendation is, that the flowers last a long time in perfection. It is a plant of less delicate constitution than many of the hard-wooded subjects, succeeding well with ordinary greenhouse treatment, and during the summer may be turned out of doors. At the same time it must be borne in mind that the delicate hair-like roots are easily injured by drought, so that during the heat of the summer this must be especially guarded against. Propagation is generally effected by cuttings that are produced when the plant is cut back after flowering. They should be 1 inch or 2 inches long, and inserted in pots of sandy peat pressed very firmly. It will be necessary to keep them close, and for that purpose covering with a bell-glass is about

the best method that can be followed. They may be kept for a time in much the same temperature as that in which they have grown, and after that, if given a little additional heat, they will root freely. The cuttings are liable to damp off, especially if kept rather moist; and to prevent this as far as possible, the glass must be removed occasionally and wiped dry. Seeds are seldom obtainable, but even if they can be got the best plants are produced by cuttings, as these latter flower much earlier and with more freedom. I once raised a number of seedlings, and found they varied considerably in the colour of the flower, some being of a very deep hue, while others were a good deal tinged with green. The perfume of some, too, was much more pronounced than that of others.—T.

SEASONABLE WORK IN PLANT HOUSES.

ROSES.—Where a constant supply of Roses is required all through the winter, the chief dependence rests on the Tea varieties, especially during the last two months of the old and the early part of the new year, the Hybrid Perpetuals coming in afterwards and continuing to give a succession during spring. The hybrid varieties furnish higher coloured flowers, larger in size than the Teas, but, nevertheless, the latter are held in such estimation in many places that the indoor supply requires to be kept up until they are obtainable out of doors. This can only be done by having a sufficient quantity of plants in reserve, so as to admit of their being brought in in relays; for though the Teas when strong keep on producing flowers from the after-growth, still where they have been kept going all through the winter they ultimately fall off. Where there is a late batch that have been kept cool, these should now be moved to the Rose house, where, if the plants are strong, they will soon begin to bloom and give a supply through the latter part of April and May. The plants of the Tea varieties that have now become somewhat exhausted with flowering during the early part of winter should be moved to a cool house or pit, where, if well attended to, they will recruit their energies. It is a moot question how long Tea Roses when grown in pots for winter forcing will last. Some of the most successful of the market growers discard their plants after they have been going five or six years, whilst others equally successful keep them on for an indefinite time. My own experience leads to the conclusion that if the plants are well cared for during the time that elapses between their ceasing to flower and again being forced, they improve with age rather than deteriorate. But success in Rose forcing depends much on the plants being liberally treated during the time they are recruiting their strength. When turned out of doors, as sometimes done with plants that have been forced, before the weather is warm enough to enable them to keep on growing, it is not possible that they can be in a condition to give more than half a crop of flowers when they are again expected to bloom. It is well at this season to look over the stock and to make sure that it is sufficient to meet the demand. Where the Hybrid Perpetuals are required in considerable numbers, if not already done, a sufficient quantity should be potted with a view to their being grown on through the summer, encouraging them to gain all the strength possible by the help of manual stimulants and keeping them free from insects.

HIBISCUS ROSA SINENSIS.—The different varieties belonging to this section of Hibiscus are suitable for covering back walls in warm houses; in such positions they not only succeed better, but also look better than many things that are often employed for the purpose. Where the plants have occupied the space required it is necessary to go over them each spring, cutting in the lateral growths so far as it becomes necessary, without which the whole becomes a confused straggling mass of shoots. Vigorous growing subjects like these soon exhaust the soil, and to keep up the requisite strength rich top-dressings should be given each spring, removing as much of the

surface of the borders in which they are grown as can be got away without undue disturbance of their roots. Besides the usual addition of rotten manure mixed with the new soil, it will be well to give a sprinkling of bone meal, which will be more lasting in its effects. Later on, when the plants are in full growth, manure water may be given freely. One of the peculiarities attached to this race of *Ribes* is, that although they attain a large size they will flower whilst quite small; little plants in 4 inch or 5 inch pots may often be seen bearing their large showy blossoms. In this way, and in the form of larger pot specimens they are very useful. Large plants established in pots should now have their branches cut in; after a few weeks they will again push growth, and should have a portion of the soil removed, giving them rich material similar to that advised for those that are turned out. Cuttings of these plants should be put in; they will root readily where they can have a brisk heat.

NERIUMS.—The old *Nerium splendens* and its white variety are the best known kinds, but several of the newer Continental varieties are well worth growing. Not the least of the merits of these plants is that they force readily, flowering equally as well in the shape of small examples in 6 inch or 7-inch pots as larger specimens do. There is sometimes an inclination in the plants, either when in a small or a large state, to cast their buds, and to this, not unlikely, may be attributed their not now being so much grown as in times past. But where this mishap occurs, it is generally the effect of one of two causes: either the plants have been allowed to get too dry at the roots after the flower-buds were set, or they have been subjected to too much heat, either of which will cause the failure in question. An intermediate temperature with less moisture in the atmosphere than the generality of forced plants require is best for these *Neriums*. Where a sufficient number of plants are at hand, a portion should now be placed in gentle heat. Although they are averse to much water overhead during the time their flowers are coming on, they still like more moisture at the root than most things.

LILIES.—Successional plants of the different Lilies that bear forcing should be put in heat to follow the earlier ones. The two forms of *L. longiflorum*, *L. Harrisii* and *L. eximium*, are the best to use for forcing; the former is remarkably free-flowered, and answers for either early or late forcing. *L. eximium* will give double the number of flowers that the ordinary variety of *L. longiflorum* will, the latter rarely coming with more than two blooms to a stem, whilst *L. eximium* when strong will yield four or five. *L. candidum* is now largely used for forcing by the market growers, but it is a somewhat difficult subject to deal with in this way. Some who have been successful with it pot the bulbs in summer immediately the tops have died down after flowering, putting about three bulbs in a 7-inch pot; these are plunged out of doors, care being taken that they get sufficient water; in the autumn they are moved to pits or frames, and early in the year they are put into moderate heat, keeping them well up to the glass in light houses. In other cases the bulbs after being potted at the time named are grown on for a year in the pots, keeping them quite cool and not attempting to force them until the second season. Needless to say, that in all cases the plants are well cared for, as if with the roots confined to such a limited space they were at all neglected, it would be useless to expect them to bloom as they should. Bulbs of *L. Harrisii* and *L. eximium* that have been forced early should, after they have flowered, be moved to a cold pit or frame, where they will be out of the reach of frost, and have due attention in the matters of air and water, without which it is needless to expect them to be of further use. *L. auratum* differs from most other bulbs, inasmuch that in any given number there will be a marked difference in the rate and time of their growth and in the time they flower. Immediately their tops appear above the soil the plants should be

stood where they will get all the light that can be given them, without which they are certain to become more or less drawn, a condition that is alike injurious to the present season's flowering and the future well-being of the plants. The different forms of *L. speciosum* should be similarly treated; these last, including the dark and the light spotted varieties as well as the white sort, are amongst the most useful of autumn-flowering subjects for conservatory and greenhouse decoration. Coming in as they do when there are fewer things in bloom than at any other time of the year makes them deserving of better treatment than they often receive.

TRITONIAS.—The common *T. aurea* is the best known representative of the genus, but there are several others varying in the colour of their flowers that are equally worth growing. Like the Lilies already spoken of, they are autumn flowerers, and desirable either for decorative use or for cutting. They are easily managed, but to have them in the best condition the pots must not be allowed to become overcrowded with their bulb-like rhizomes, a state which they are apt to get into if not divided often enough. When this occurs the flower-spikes come fewer in number and individually smaller than when better treated. Plants that are deficient of room may now be divided, but unless where the intention is to increase the stock as far as possible it is better to only separate each plant into two, three, or four, for if the roots are separated more than this they are liable to get injured so as to interfere with their growth for a time. Give pots proportionate in size to that of the plants, so that they will have enough room for two years without being again disturbed. After potting, a cold pit where they can be kept out of the reach of frost will be the best place for them during the spring, until the time comes that they may be put out of doors. The plants being nearly hardy will keep on growing in a lower temperature than would suit many things.

SCHIZOSTYLIS COCCINEA.—This is another desirable plant that keeps on flowering through the autumn and early part of winter. Though hardy, it may in reality claim to be better adapted for pot culture than for growing in the open ground, as, unless protected, the flowers, which keep on appearing in succession, are almost sure to get cut off by frost. Its tuberous roots increase fast, and must not be let suffer for want of sufficient room, or the bloom will suffer in proportion. The present is a good time to divide any plants that want more space; it is best grown in moderate-sized pots, say about 8 inches in diameter. This *Schizostylis* succeeds with treatment such as advised for the *Tritonias*. Ordinary loam with some sand added is the soil required. T. B.

KITCHEN GARDEN.

W. WILDSMITH.

EARTHING-UP VEGETABLES.

Is this a necessity as regards vegetable culture? To this question a few years ago I should have said, yes, decidedly; but experience has changed my views, and now the answer I have to give is both yes and no, a paradox which I will attempt to explain. Having a very light, and, though deep, a rapidly drying-up soil to deal with, this question of earthing up forced itself on me in this wise. After a prolonged season of drought we were favoured by a grand rain, and amongst other crops that came to my mind whilst watching and enjoying the descent of the rain was a fine piece of Cauliflowers that had lately begun to show signs of distress, owing to lack of water. Imagine my disappointment, therefore, on taking a survey of the crops next day to find the Cauliflowers in question but little the better, if any, for the heavy downpour there had been. I procured a fork, dug up a couple of the plants, and with astonishment found that not a drop of

moisture had reached the last made and most important feeding roots. And now for the cause; the plants had been earthed up, and the water had run off the ridges like water off a duck's back; though it found its way into the soil, the greater portion of it was lost, as but few roots extended to the middle of the space between the rows. This forcible illustration of the evils attending earthing up, without thought as to whether the operation was likely to be injurious or the contrary, but simply because others did it, had, and still has, a reforming effect on our future procedure. Earthing up we still do, but not promiscuously, or without thought or reason. Moreover, when we think it necessary to be done, we wait till there has been a soaking rain, so that the ground is likely to continue moist under the ridges for a long time, even though following rains do not get through them. Dwarf strains of Cauliflowers, Coleworts, and Cabbages we now never think of earthing, but tall-growing kinds of Broccoli, Kale, and Brussels Sprouts must be earthed, even if only to prevent wind-waving. Apart from this, the practice is of little benefit. Peas we earth up in early springtime, only by way of protection from cold easterly winds; at all other times we prefer to mulch with a little long litter, which has the merit of guiding the rainfall directly to the roots. Potatoes, except very strong-growing kinds, we earth up but slightly, and this solely to prevent the tubers from protruding above the soil. To obviate the necessity of earthing up any kinds of Potatoes whatever, we once tried deeper planting of tall-haulmed varieties, but it proved a failure, for it was with difficulty the haulm found its way through the soil, and the crop of good tubers was less than half of that from others planted in the usual way. It should be noted that these remarks have reference to very light soil only; on heavy retentive soils earthing up would not be likely to prove injurious, but rather the contrary, for the ridging up would act as a sort of air drain to prevent the wet soil from becoming stagnant.

Pea Criterion.—This excellent variety has been in cultivation for several years, and if I am rightly informed it has steadily gained in popularity, immense quantities of seed now being annually sown. It is by no means a sensational podded variety, being in fact quite the reverse, but its good qualities will keep it in cultivation long after more showy sorts are as good as extinct. Criterion is suitable for affording a second early supply, and also for the main crop. It does not branch so much as Telephone, one of its parents, or Ne Plus Ultra, and should therefore be sown rather more thickly than these sorts. A height of about 5 feet is usually attained, but under favourable circumstances it reaches 6 feet and upwards. It produces an abundance of medium-sized well-filled pods, both these and contents bearing a close resemblance to Ne Plus Ultra, the quality almost equalling that popular variety. Lovers of really good Peas, instead of growing all the varieties they can afford to buy or fancy they require, may well confine themselves to four of known excellence. Commencing with the dwarf American Wonder, this may be closely followed by William I., or, better still, a wrinkled selection from it appropriately named William II. Telephone would form a good succession to this, and be in its turn closely followed by Criterion. Two or three sowings of the latter could be made, and if Ne Plus Ultra is used for the last, and at fortnightly intervals subsequently up to the end of June, this, other conditions being favourable, will prolong the supply till frosts intervene. Not only will the produce be fit for an epicure, but the crops will be abundant, that great enemy of Peas, mildew, not proving so destructive to Ne Plus Ultra as it is among less robust sorts. Nor is Criterion so much addicted to mildew as numerous second early and

main-crop sorts I could name. Although tall Peas are the most profitable, all cannot afford either space or stakes for them, and in this case I would substitute Stratagem for Telephone, either Gladiator or President Garfield for Criterion, and Veitch's Perfection for Ne Plus Ultra, Sturdy being also a first-class late sort.—W. I.

ONIONS FOR EXHIBITION.

ONIONS form an important part of a collection of vegetables, and in order to have them in good condition during the autumn months, their cultivation must shortly be started. Rousham Park is the best kind for exhibition; it grows to a large size, is of good shape, and excellent in colour. Seed of it should be sown at once in boxes, in light, rich soil; place the boxes in a Peach house or vinery just started, where the night temperature is kept at about 50° or 55°, with a corresponding rise during the daytime. As soon as the young plants push through the soil, they should be placed near the glass in order to prevent them from becoming drawn up weakly; as they progress, gradually harden them off until they can be moved to a cold frame, and as soon as the second leaf is formed they should be transplanted into light, rich soil about 4 inches thick, at the bottom of which is a layer of horse manure 2 inches thick; into this the roots quickly find their way, and the plants quickly start again into growth. They are planted out into their permanent quarters in the garden about the middle of April, and by that time they will be sturdy and strong, *i.e.*, if air has been admitted on all favourable occasions. An open piece of ground in the kitchen garden deeply dug or trenched and well manured the autumn previous suits them admirably, and before planting give it a sprinkle of wood ashes and soot, which will get raked in and mixed with the soil. Plant in rows 15 inches asunder, and as much apart in the rows, *i.e.*, where space is available, but where it is not, 10 inches or 12 inches will do. Plant with a trowel, so that a good ball of soil may be attached to each plant, and tread the soil firmly about it; do not plant too deeply, allow the bottom of the bulb to be just under the surface of the soil; as growth proceeds, if the weather be dry, apply water freely, and occasionally give doses of liquid manure, or thinly sprinkle around each plant some artificial manure, and water it in. Dissolved bones are excellent for this purpose, and may be applied about every three weeks after the bulbs attain the size of hen's eggs.

M. S.

Mushrooms failing.—I see that "J. G. II." attributes a good many failures to too shallow beds, and goes on to say that to make up a bed less than 1 foot thick is to court failure. Now one of our beds was made up on October 29 last year, spawned on November 6, and first showed young Mushrooms on December 18; this bed is 17 feet long, 3 feet 3 inches wide, and 9½ inches deep, so that the depth of manure is really less than 9 inches, as upwards of an inch of soil is used in sealing the bed down. The spawn was inserted 3 inches deep and about 8 inches apart. I could not give the exact temperature of the bed at spawning time, as we had no thermometer plunged in it. We have employed artificial heat during the late severe weather in order to keep up the temperature to 55°, and no one could wish for a better supply of Mushrooms than that which we have had. Provided the bed is well beaten, so as to make it firm, and the manure is in proper condition, Mushrooms can be grown even in beds less than 1 foot in depth.—G. S.

Preparing Seakale for forcing.—The most economical way of raising a stock of Seakale roots for forcing in the Mushroom house, or in pits, is to plant now the small thongs or roots which are trimmed off the large roots when they are lifted for forcing. In December, when the bulk of the roots is lifted, in preparing them for forcing, all the projecting roots are trimmed off, and the tap-root also is shortened. Some of these thongs are as thick as one's finger, and the best, to the number required,

are laid in damp sand till some time in March, when the land is in a suitable condition for planting. The better the condition of the land, the stronger the roots will be, with crowns of corresponding size and vigour. Plant with the dibble in rows 18 inches apart, and 15 inches between the plants in the rows. Few crops cost less to cultivate, as the only attention required is to keep down weeds by hoeing and to pinch off all flowers as soon as they appear. The sets should be about 4 inches or 5 inches long, though smaller pieces will grow, and the upper or thick end should be just covered with soil. Seeds sown now will also under good culture produce roots large enough to force the same season, though I do not think anyone with a stock of roots will require to sow seeds, except it may be in cases where the stock of roots falls short of the demand. Seedlings when they emerge from the soil are exposed to some difficulties; snails and slugs are fond of them, and so also are the Turnip beetles, and in some soils and seasons frequent dressing and a freely stirred surface will be necessary to enable the young plants to pass the spring safely.—E. H.

KITCHEN GARDEN NOTES.

RHUBARB.—Usually we defer filling up vacancies in old and the making of new plots of Rhubarb till forcing is over, as then the forced roots are available for the purpose, but circumstances being favourable, we are doing the work now, the plants being procured by lifting the largest roots from the old bed and cutting them with an edging iron into pieces having a couple or three crowns to each. The ground has been well prepared by deep digging and manuring, and the roots are planted at a distance of 3 feet by 4 feet; the soil, being light, is well compressed round about the plants, which are planted so deep that only just the tips of the crowns are visible. A heavy mulching with long litter will next be given, and there will then be no further trouble all the summer, except an occasional hoeing to keep down weeds. The roots remaining of the old plot will now be covered with pots, but no litter or leaves will be used, this being unnecessary at this season when growth is starting naturally. The lifted roots that are now producing the supply will be used for making good the vacancies in the plot from which they were lifted.

SEED SOWING.—The last few days of drying weather have acted so favourably on the soil, that a good seed bed is assured, and before these lines appear we hope to have sown the main crop of Onions and Parsnips, both of which cannot be got in too early. Another sowing of Peas will also be made, and a quantity of Potatoes be planted on a dry southern bank. We never use dibbers for this work, because at this early season all our Potatoes are started in leaf-soil, and so there must be room to lay the roots at full length on the soil, and this we do by drawing wide drills, in which the sets are laid at 1 foot apart and 18 inches from row to row, and the whole are covered in with about 5 inches of soil. The old Windsor Broad Bean will also be sown to succeed the Longpod variety that was sown a few weeks since. Spinach will also be sown between the rows of Beans. It is also time to sow another small lot of Cauliflowers, Kale, and early Broccoli. All of them we sow in drills on a warm bank, and so thin that it is not necessary to prick them out, as they transplant very well from the seed bed. Early Munich Turnip, Leek, Radish, Salsafy, and Scorzoneria will all be sown within the next few days.

POTATOES IN POTS.—Being short of frames for forcing purposes, we always grow a few of these in pots, as they can be conveniently shifted from time to time from one house to another, according to their requirements. At first they occupied space close to the front lights of an early vinery, but this getting too warm and shaded with Vine foliage they are now moved into a Peach house, the trees of which are just opening their flowers, and from this place they will probably have to be shifted to the latest Peach house. Three sets in a 9-inch

pot produce a large dish of tubers, which are prized very highly, because they are ready so early, and also because they prevent the necessity of commencing to dig the frame tubers till they are full grown. We have just given them a slight earthing up and sprinkled a little artificial manure on the surface of the pots, which as water is given will get gradually washed into the soil. Such restricted soil space renders liberal feeding a necessity.

RIDGE CUCUMBERS.—Provided there is frame space for an early crop, the first sowing may be made now, but if the plants are to be grown on ridges in the open, with but slight heat from litter and lawn mowings, a month hence will be sufficiently early to sow, as the plants would only get crippled by being pot-bound before it is safe to plant out. The variety King of the Ridge, when it can be had true, is such a good type of ridge Cucumber, that it might pass muster as a first-rate frame sort, not to mention its hardness and heavy productive qualities; in fact, for some years past we have taken no pains about getting any other sort early in the season and up to midsummer, and by that time the plants on the ridges in the open begin to fruit and continue doing so to the end of September; thus a supply of fruit from 9 inches to 12 inches in length may be had without frame or house room all through the summer months. It is best to raise the seeds singly in 3-inch pots, and grow them on with as little check as possible and with but a moderate amount of heat—from 55° to 60°; good loam, with the merest smattering of leaf soil and charcoal, is the best of compost in which to grow them, and it should be given them by degrees, *i.e.*, as the roots appear on the surface, for if put on in bulk at once, the mass gets soured before the roots are ready to make use of it. Next to this piecemeal adding of soil the most important point of culture is to avoid overcrowding the shoots; the plants resent this neglect of attention by failing to set their fruit; no light, no sun can get at the flowers, hence their turning yellow and dying off. Stop or pinch, peg down, and otherwise regulate growth at least once a week. Water abundantly in dry weather, and when in full bearing an occasional watering with manure water is of great assistance.

VEGETABLE MARROWS.—Very much the same treatment is required for Marrows as for ridge Cucumbers. It is not, however, necessary to be over-particular as to the description of soil. I have known them do just about as well planted on a rotted leaf soil heap and on the refuse heap of old potting soil as in a properly prepared compost, which, in my opinion, should be pure loam of medium texture. If stable litter be plentiful, then as much can be afforded to make up a bed of sufficient bulk as to generate a heat of about 60° after the first heating is over. The best way to raise the plants is to sow them on the mound where they are to grow, and protect them with hand-lights till they get strong, and the weather safe for their full exposure, which may perhaps be about the middle of May; consequently sowing ought not to be done before April, except for early fruits intended for growing in frames, and for this purpose it is not too early to sow at once, after this manner, a couple of seeds in a 4 inch pot; let the soil be light loam, and the heat that of a Cucumber frame; the pots need not be plunged, as bottom heat is not essential. The plants should not be separated, but be planted on the mounds in double form as turned out of the pots, thus growth would be continuous, and fruit ready several days earlier in consequence. Moore's Cream and Long White are old, but still the best varieties. Those who prefer small fruit should try Custard and the new variety Pen-y-hyd; both of them are very productive and as hardy as any.

RARE GREENS.—Brussels Sprouts, Cottagers' and Curled Kales seldom get so severely crippled as they have been this winter. Up to the present they have all produced moderately, but the end has nearly come; and Broccoli make but little sign of heading, as they, too, have got hardly hit,

and quite a third of the whole are killed outright, so that we are glad to have a reserve of greens on the farm in the shape of Rape, which, though sown for sheep feed, is much relished in the dining-room, and is pronounced delicious and quite equal to Brussels Sprouts. Such being the case, it occurs to me that we might do worse than spare a plot in the garden for what many consider a very rough type of Cabbage, and which it is, but its hardness and good quality counterbalance the roughness in this season of scarcity of green stuff. For the information of anyone who may be disposed to give the plant garden space, I may say that those from which we are now obtaining supplies were sown about the middle of July broadcast, and intermixed with Turnips, and thinned out by hoeing as soon as the plants were about a couple of inches high. A better plan would be to make a sowing in drills, and plant out in the same way as ordinary Cabbage. The ground need not be very rich, as I note that the produce varies but little over a field of several acres, some parts of which I should consider very poor land indeed.

GENERAL WORK.—Having nearly completed the rough, heavy work of trenching, soil and manure wheeling on to the various plots, we are now repairing the Box edgings and walks. The latter we lightly fork over, and then apply just a surfacing of new gravel for appearance sake, and next roll them till quite firm. Cutting sticks for Peas that have been raised in pots, and which will be planted out at an early date, staking being done at once to afford shelter from cold winds as well as from destructive birds. Renewing the linings round frames of Potatoes and Asparagus, and planting other batches on beds with improvised frames, made with long Hazel rods, on which to lay coverings of mats. Lifting more Parsley roots for planting in boxes and placing in heat, also a last lot of Mint. Pricking out Brussels Sprouts and Cauliflowers in cold frames, and part of the autumn-sown plants wintered in frames will be planted as soon as time permits.

TREES AND SHRUBS.

W. GOLDRING.

THE SWAMP OR PIN OAK.

(*QUERCUS PALUSTRIS*.)

AMONGST American Oaks now under cultivation in Europe, the Swamp Oak is undoubtedly one of the most valuable as regards ornamental

Branch of Pin or Marsh Oak (*Quercus palustris*).

planting. Michaux, who knew North American trees as they grew in their native homes better than most people, considered it a handsome tree; and Loudon says "its agreeable pyramidal shape,

its far-extending, drooping branches, its light and elegant foliage, render this tree the most graceful of all the Oaks." Loudon's opinion quite accords with our own, but it is singular that neither he nor any other writer has pointed out what to me is the most important and most beautiful feature of this Oak, viz, the rich and delicate shades of orange and red which its foliage assumes in early spring as well as in its decaying stage in autumn. As an ornamental tree this constitutes its chief merit, and this one fact is far more worthy of consideration, from a planter's point of view, than a long account of how it differs in minute botanical characters from its near relatives. The Swamp Oak is one of those trees that are met with only in old and richly-stocked arboretums, planted perhaps two or three generations ago. One rarely meets young trees of it, and it is not a common stock plant in nurseries; but if planters fully appreciated its merit, especially as regards its beautiful effect in leafing-time, it would undoubtedly become popular. It is different from most other Oaks, inasmuch as it is of rapid growth. With the exception of the Grey Oak (*Quercus ambigua*), Loudon states that it is the fastest-growing of all the American Oaks. My own observation accords with this, for trees of it which I have seen in various arboreta have generally overtopped other Oaks in the same place. It is easy to distinguish a tree of the Swamp Oak from others, even in winter; it always has a denser head than that of others, small twigs being exceedingly abundant. The outline of the head is rounded much in the same way as that of the Quercitron Oak (*Q. tinctoria*), and the bark of young trees is particularly smooth and of a dark ashen grey. The leaves, like those of several other North American Oaks, are deeply lobed in the case of trees of good size, and each lobe ends in a bristle-like point. But they are smaller than those of such species as *Q. rubra* and *tinctoria*, being when fully grown only about 6 inches long by 4 inches wide. On young trees they are much less lobed than in those of greater age, and a seedling has leaves scarcely more lobed than those of our native Oak. This alteration in leaf form was of great interest to Michaux, who in his elaborate work, "Histoire des Chênes," published in 1801, dealt with the subject at great length. The other distinguishing characters of *Q. palustris*, such as those relating to the size and form of the Acorns, need not be gone into here, as the illustrations given herewith show them well. I remember seeing last spring a charming picture in a Surrey garden in which the chief subjects were the Swamp Oak and a Copper Beech planted in proximity to each other, so that the pale yellow hue of the one was heightened by the rich ruddy tints of the other. In autumn the Oak was even richer in colour than the Beech. A beautiful tree, such as the Swamp Oak is, could be combined in many other ways, and it ought to be cheap and easily procured in English nurseries. As regards the best position for the Swamp Oak, I cannot say much; the trees of it which I have seen have generally been planted in the usual way followed in arboretums. I have never yet seen a tree growing in a swampy place which one would imagine, judging by its name, is best for it. It is, however, not naturally a swamp tree, and Dr. Blomfield was of opinion that the name *palustris* was erroneous. Attached to his dried specimen of the tree collected in 1847, and preserved in the Kew herbarium, there is an interesting note about it, in which he states that, "Although this Oak prefers a somewhat moist soil, it is usually found growing in open pastures in the vicinity of the banks of rivers and streams." He also says that some trees with which he met in the Southern States of North America were

among the tallest and largest trees he ever saw in those parts. From this it would appear that a damp place is not essential to this Oak, and, judging by the vigorous growth of specimens of

(a) One-year-old seedling of *Quercus palustris*, showing leaves slightly lobed. (b) An older leaf more deeply cut.

it on dry soil in the Kew arboretum, this opinion is doubtless correct. This Oak grows wild over a wide area in North America. It extends from Lake Winnipeg, in Canada, throughout all the Eastern States to Kentucky and Virginia. It rarely forms forests, but is generally found growing in isolated positions or in scattered groups. It grows as high as 80 feet, and as much as 3 feet and 4 feet in diameter. Of its wood I know nothing from personal observation, but it is said to be fairly good. It was introduced to this country about the year 1800, and about fifty years ago, which may be called the tree-planting age, it was tolerably plentiful in nurseries and much planted. There is a dried specimen of it in the Kew herbarium cut from a tree growing

Fruiting twig and full-sized Acorns of Pin or Marsh Oak (*Quercus palustris*).

at Warwick Castle in 1823. This Oak is perfectly hardy, and as the young foliage does not appear till spring is well advanced, it does not suffer from late frosts.

Prunus sinensis alba plena.—This is a slender-growing member of the Plum family; indeed, much more so than the better-known *Prunus triloba*, but, like it, remarkably handsome when in flower. The habit of the plant is dwarf and bushy, and now, where it has been forced, all the principal shoots are completely clothed with small rosette-like blooms of a pure white colour. As a shrub for forcing, it possesses some advantages over many other subjects, one of them being that the same plants may be forced year after year, and, if necessary, kept entirely

in pots, provided growth is encouraged by the application of manure water or some other stimulant during the growing season. Not only is this a handsome little shrub for forcing, but it is also well suited for planting in the open ground in spots where a subject is needed that can be easily kept within bounds. I have seen it trained to a low wall, where the blooms, protected against unfavourable weather, made a goodly show. For larger walls, however, it is not vigorous enough to compete with its ally, the bright-coloured *Prunus triloba*.—H. P.

Vaccinium Sprengeli.—This is a pretty little greenhouse shrub of a dense, much-branched character, with slender wiry branches, all of which as well as the minor branchlets are terminated by clusters of small bell-shaped blossoms. Their colour is white, suffused on the exterior with a pinkish tinge. The foliage is small, bright green and always cheerful in appearance, while the flowers, like many of the same class, last a long time in perfection. It is one of those subjects that can be depended upon to flower at the proper season, provided it receives ordinary care and attention, and gives but little trouble in the way of potting, for once established the roots need not be disturbed for years. An open sandy peat is the most suitable compost for this, and in potting, the soil must be pressed down firmly, while the drainage requires careful attention. The red berries that succeed the flowers are an attractive feature later on.—H. P.

Wellingtonia gigantea.—It may perhaps interest your readers to have some account of the growth made by a *Wellingtonia* which we cut down to make room for two other specimens. The tree was planted in the spring of 1870. It was then about 2½ feet high, and when we felled it, it measured 39 feet 6 inches in height and 8 feet 6 inches in girth, and was a perfect specimen of what a *Wellingtonia* should be. It grew on the border of the fen, over a sub-soil of harsh clay, and the roots which it made were something marvellous. Conifers thrive well on fen soil without any extraneous mixtures of peat and clay. In fact, I do not remember seeing trees in better condition. We have some fine specimens of *Cupressus Lawsoniana* and its varieties, *Thuopsis* and *Cryptomerias*, *Yews*, *Cephalotaxus*, and others which have developed in a very short time into grand trees.—W. A. COOK, *Holme Wood*.

Andromeda japonica.—Some bushes of this that were lifted from the open ground in the autumn, and after being potted were kept in a cold frame throughout the winter, are, with the little additional heat given them for the last few weeks, in full flower. The long pendulous racemes of pure white flowers contrast well with the deep green of the neat foliage; and another prominent feature just commencing to manifest itself is the bright crimson tint of the young leaves, which, when the plant is studded with growing points, gives it at a little distance quite a ruddy hue. This kind differs in many respects from another of the same genus—*Andromeda floribunda*, a North American kind, that flowers about the same season; but in this the blooms are borne in shorter and stiffer clusters, thus the whole plant is wanting in the elegance of the Japanese *Andromeda*. As outdoor shrubs, however, as far as my experience extends, the American variety is less liable to injury from late spring frosts than the other, though, leaving the flowers altogether out of the question, *Andromeda japonica* is well worth growing as a very ornamental evergreen shrub. There is of this, too, a variety in which the leaves are irregularly margined with white, and very pretty it is when planted in a fairly moist soil and not in too hot a situation. Potted up it is bright and cheerful throughout the winter and early spring months. The dense rooting character of these shrubs, in common with most other Ericaceous plants, renders it possible to lift them at almost any season of the year without injury, providing, of course, a reasonable amount of care is exercised

in carrying out the operation. *A. japonica* can be readily increased by cuttings of the half-ripened shoots put firmly in sandy peat, and kept close and shaded till rooted. Both the *Andromedas* mentioned are also to be met with under the generic name of *Pieris*.—T.

SHRUB NOTES FROM PENRHYN.

THE DAPHNES.—There is a woodland on this estate that every time I pass it, during winter particularly, stop I must and admire the conspicuous shining foliaged, sweet-scented *Daphnes*. I am here referring particularly to the Laurel-leaved *Daphne* (*D. Laureola*), for certainly, barring the Holly, I know of no plant that can impart the same amount of warmth and comfort to a deciduous wood as the shrub in question. Then it is so inexpensive, so easily grown, spreads with such rapidity, is so perfectly hardy and accommodating, affords such an amount of shelter, and is so truly imposing and pretty, so deliciously fragrant when in flower, that the only wonder is why it is not more commonly seen massed irregularly around the outskirts of our woods for winter effect. A few plants placed here and there will soon stock a whole wood, for it seeds freely, spreads from the root in a short space of time, and forms layers by the branches coming in contact with the soil and rooting freely. I fancy, in judging from the plants here, that in opposition to the *Mezereon* (*D. Mezereum*) the Laurel-leaved plant prefers a warm, dry, sandy loam, for it certainly succeeds best under these conditions in the wood above referred to and where fully exposed to the sun. A quickly sloping, southern-facing, sandy bank has become almost covered by this plant, and presents during the flowering season a pretty and effective sight. The *Mezereon* must not, on account of its deciduous character, be condemned for the ornamentation of our woods, as pick as you will you cannot find during the early spring months a more beautiful flowering shrub. It is of easy culture and naturalises itself quite readily in any favourable wood or thicket, always preferring dampish ground and a somewhat shady situation. When in fruit it is a sight well worthy of going out of one's way to have a peep at; in fact, as a good all-round woodland plant it is not far behind even the best.

OTHER GOOD SHADY PLANTS.—On the whole, and when one comes to turn over in his mind the number of shrubs that will thrive in a fairly successful manner beneath the shade of our forest trees, the list swells to one of large size. What can be more ornamental for semi-shady corners than good, bold patches of the *St. John's-wort* (*Hypericum calycinum*), the *Vineas* (*V. major* and *V. minor*), *E-callonias*, *Skimmia japonica*, *Per-nettya mucronata* and its variety *angustifolia*, *Phillyreas*, the *Bateher's Broom* (*Ruscus aculeatus*), the *Dogwood*, *Euonymus*, *Brambles* of sorts, the *Snowberries*, *Mahonia aquifolia* and *M. japonica*, *Laurel* (*Portugal* and *common*), and the well-known *Laurustinus*. With such a list to pick from who would have his woodlands bare and cheerless, or who would neglect to cover the untidy, grass-bare spots beneath his lawn *Beeches* and *Limes*? Being of low, creeping growth, the *St. John's-wort* and *Vineas* are particularly well adapted for edging paths and walks in the woodlands, while the taller growing *Mahonias*, *Per-nettyas*, *Honeysuckles*, *Yews*, and *Elders* may find suitable places at a greater distance from the frequented roads and walks. In planting the *St. John's-wort*, we have found it best to cut, from some places where it runs wild, squares of the plants and their roots with the attached soil, and to transfer these intact to the intended positions. It is not necessary to plant closely; we have found for 18-inch square tufts a distance of 3 feet close enough, as the roots soon run about underground and send up shoots in all directions. The *Vinea* is more difficult to manage, but with care in planting and by having well-rooted clumps to start with, it soon becomes established and runs wild amongst its neighbouring vegetation. A

very pretty and attractive bank may be formed by planting the *St. John's-wort* and *Vinea* in combination, the co-mingled yellow and blue flowers being particularly pleasing.

THE OVAL-LEAVED PRIVET AS A HEDGE PLANT.—This (*Ligustrum ovalifolium*) is far superior to the ordinary form as a hedge plant, being of stronger and freer growth as well as with a far greater inclination to retain its foliage during winter. In this latter respect it is, indeed, almost an Evergreen, for if cut in during the late summer months it soon throws out numerous shoots that remain fresh and green even during our severest winters. Planted alone, it forms one of the prettiest and closest of garden fences, and bears trimming so well that repeated switchings but increase its value and appearance. Another valuable point is this, that the *Privet* in question is, when suitably placed, of very rapid growth, it requiring but two years to get up a well-formed, serviceable hedge, and that even in partially exposed situations provided the soil is good. We have some fences of this *Privet* not a foot wide at base, and perfect wedges of 6 feet in height, so close and firm of growth is the plant. Strong, well-rooted plants of nearly a yard in height should be used in the formation of hedges of the oval-leaved *Privet*, and these, if planted in well-prepared ground and at 15 inches apart, will, in two years, make one of the most serviceable and prettiest of fences. The oval-leaved *Privet* has not been long in use in this country, but it is certainly rising gradually, but surely, in the estimation of planters. For ease of propagation it has few rivals, cuttings inserted at the right season and the right class of soil taking root and shooting away rapidly. As a game covert plant I have not much faith in this plant; it is of too strong, unyielding growth and wanting in the clampering, creeping properties of the normal form. A clump of a hundred or more plants placed in an open portion of the wood, and attended to regularly in the way of pruning and heading over, is, however, a by no means unornamental feature; and if the plants are kept far apart and well headed down and hard cut back annually, game have no objections to rest under their shade.

ELDER IN WOODLANDS.—Although occasionally we hear of the *Elder* being recommended for covert purposes in our woodlands, it is not by any means desirable for this purpose; such at least is the experience of one who, unfortunately, has had too much to do with the plant in the way of extermination. It is a regular nuisance, an unprofitable plant, and like all of such a class grows far too rapidly, and spreads about in a most mysterious manner. We expend a great deal of time and labour in annihilating this plant, for all the sportsmen who visit our game preserves are enemies to the *Elder*. It is good enough in summer, and when of low stature for covert purposes, but during winter when destitute of foliage, and especially when of large size, it is about as useless an underwood plant as one could imagine. Far better to grub up the *Elder* and allow other and better natural vegetation to take its place. It is, perhaps, unnecessary for me to say that in striving to get rid of the *Elder* it should never be cut over, for, cut low as you will, the stocks will send out abundance of shoots, and the last state of that plant is worse than the first. Take a grubbing axe or pick and uproot the *Elder*, and then only will you get rid of it; but, indeed, in many instances, not even then have you destroyed its vitality, for it is no uncommon thing to see *Elder* stems without a root in contact with the ground, sending forth, in moist woods particularly, an abundant crop of shoots. Burning of the uprooted plants should be set about at once, unless, indeed, some butcher cares to have them for the making of skewers.

Hard as we are on the common *Elder* for underwood in our woods, yet some of the varieties are amongst the most ornamental plants we possess, their scarcity being alone to be lamented. The gold-striped, silver-edged, scarlet and white-berried, as well as the cut-leaved, are very desir-

able shrubs for ornament, and should be sought after and planted in suitable places.

A. D. WEBSTER.

Andromeda japonica.—At one time this pretty evergreen shrub was considered much too tender to stand our winters, but it has proved far hardier than was anticipated. In the Knap Hill Nursery, Woking, where it is grown largely, being a great favourite with Mr. Waterer, it stands out quite unprotected, while others which have been protected by a cold frame are coming into flower, each strong shoot being terminated by a graceful cluster of flower-buds, which in a few weeks will present a beautiful sight. The pretty shining green foliage of this shrub renders it quite ornamental, even when not in bloom. Perhaps its greatest value is as a greenhouse pot shrub for early spring bloom, for there is not a more elegant shrub cultivated for the purpose.

The Oak-leaved Arbutus (*A. Unedo quercifolia*) is a little-known, yet handsome, shrub quite distinct from any other variety of *Arbutus*, or, in fact, any other shrub. It is denser in growth than the ordinary form, forming a compact, dense bush. The name *quercifolia* is appropriate, as the leaves resemble those of the common Oak in regard to their lobes and outline. The leaves have crisped edges, which being of a much lighter green than the rest of the leaves, give quite a distinct look. The stalks of the leaves, moreover, are red, as are also the leaf-veins and bark on the stem, and this colour is seen throughout the year, but is most noticeable in winter. It is not a common variety in nurseries, but is unquestionably one that should be taken up by nurserymen.

The dwarf Weymouth Pine.—The pigmy variety of *Pinus Strobus* is a tree that could be put to good use in ornamental planting, for there always occur positions where one would like a small-growing tree or shrub that would not outgrow its bounds and mar the intended effect of grouping. The dwarf Weymouth Pine is a tree that one need never fear would outgrow its allotted space, for it never gets more than a few feet high, and always forms a dense rounded mass of that beautiful soft bluish grey tint which renders the glaucous-leaved Pines so telling in tree grouping. There is a plant of the dwarf Weymouth in the old tree nursery at Knap Hill that has occupied the same spot for many years, and now it is only about 4 feet high and some 6 feet or 8 feet through. The place to plant a tree of this kind is a prominent outlying part of a large group or mass of trees, a spot where it could be well seen. It should have been included in the list of Scrub Pines given a short time ago.

The Golden Lawson Cypress.—I heard it remarked the other day that most of the Golden Conifers are "frauds." That is so. Among the few that are not "frauds" is *Cupressus Lawsoniana lutea*, which I consider one of the most strikingly attractive among all the Golden Conifers. I thought so the other day when I saw in the Knap Hill Nursery a plantation of several hundreds of this tree shining in the midday sun like burnished gold amidst the luxuriant greenery with which this plantation was surrounded. I thought at the time that I never saw a more effective sight in any nursery. Every tree glowed with a uniform yellow; no green or shabby patches, which mar the appearance of other so-called Golden Conifers. The Golden Lawson Cypress is one of the "good things" among trees, and, like many other good things, should not be abused. A few in a place would heighten the effect of other trees. Many scattered about indiscriminately would give to any place a jaundiced aspect. The great value of the Golden Cypress is that it retains its yellow hue throughout the year, and is unaffected by the winter's frosts or midsummer's suns, and everybody knows what a capital tree this Cypress is in almost any soil or aspect.—W. G.

SHORT NOTE.—TREES AND SHRUBS.

Magnolia Halleana.—This *Magnolia*, which has attracted so much attention of late, opened the first bloom to-day (February 25) under glass, and a succession is likely to be maintained for some little time. In the greenhouse

the flowers are safe from inclement weather, which is very liable to injure them, as well as those of the more vigorous, but allied, *Yulan* (*M. conspicua*) when they open outdoors.—H. P.

PROPAGATING.

TREE CARNATIONS.—Where these plants have been kept in a genial temperature throughout the winter for the sake of their flowers, they will now have made a considerable number of young shoots which may be used for propagating. Plants struck thus early in the season have plenty of time to attain a good flowering size before the winter. The cuttings will strike well if kept close in a temperature rather above that in which they have been grown. In taking the cuttings it should be borne in mind that the very stout, succulent shoots do not strike so well as more slender side branches, for the former are liable to decay, and besides, even if rooted, they do not branch out so freely afterwards. The cuttings should be formed entirely of the current season's growth, and must not be too long, as if that is the case they are more difficult to root. A length of about 4 inches is sufficient, and, the bottom leaves having been removed as far as necessary, the cutting is then ready for insertion. A very convenient sized pot for this purpose is one about 4 inches in diameter, and this should be drained with broken crocks to about one-third of its depth, and the remainder made up of soil with a layer of silver sand on top. In a compost consisting of loam, leaf mould, and silver sand, in equal parts, they root readily, and when potted off generally carry a good cluster of healthy fibres. The soil in the pots should be pressed down moderately firm, and in inserting the cuttings care should be taken that the whole of the underground portion is in immediate contact with the soil, and no open space allowed to exist at the base, for if such is the case the cutting is very liable to shrivel up and perish. One of the most common errors a novice at propagating commits is to insert the cutting in such a way that the soil does not close up around the underground portion, and consequently the air has access to the base thereof, and especially in the case of delicate subjects is very liable to cause them to perish. The better way to put in a cutting so that such a mistake will not occur is to make the hole just as deep as required (which, rather difficult at first, becomes easy with practice); then place the cutting in position and insert the dibber perpendicularly in the soil at about half an inch from the cutting. If the dibber is pushed down as far as the buried portion of the stem and then slightly pressed towards it, the entire hollow will be completely filled up. The Carnation cuttings, after they are inserted in the pots, must have a good watering, when, if they are placed in a close propagating case or kept in some way to prevent too rapid evaporation, they soon root. One caution to be observed is that the cuttings are quite free from aphides, which greatly injure the young shoots, and care must also be taken that they are not allowed to remain in the close atmosphere of the propagating case longer than is necessary, as they then soon become weak. To obviate this as far as possible the young plants must be kept close to the glass during their earlier stages.

RHODODENDRONS of the hardy kinds are usually grafted on seedling stocks of the common *Rhododendron ponticum*, and the present season is the best for the purpose. The stocks are potted up in the autumn, and sheltered in a cold frame or in some rather favoured spot; then, two or three weeks before they are required are placed in a gentle heat, in order to incite a more rapid circulation of the sap. Various methods of grafting may be employed, but that most commonly used is known as saddle grafting, in which the stock is fashioned in the shape of a wedge, and the scion having had a corresponding piece removed is put in position and tied securely in its place. The grafts are formed of the preceding season's growth, and the bark of the stock should be as near as possible in the same condition as that of the scion. In grafting, the chief point is to fit the two portions as closely together as possible. If they are then placed in a close case under glass, kept at the temperature of 50° to 55°, no clay or grafting wax is necessary, and in six weeks or thereabouts, many of them can be re-

moved from their confined quarters. This should be done very gradually, and at the same time it must be borne in mind that all are not ready at once; consequently before any air is given, the plants should be gone over, and those that are undoubtedly united remove to one case, while the doubtful ones are placed in another. The change to more airy quarters must be gradually effected, and in time the plants can be removed to a cold frame. A point of great importance with nearly all plants confined in close cases is, that the lights should be taken off for an hour or so every morning, otherwise the air of the case becomes so much saturated with moisture that decay is often apt to set in. Though enormous quantities of *Rhododendrons* are raised in this way by nurserymen, but few others attempt the operation, as considerable appliances are needed, and the room in the propagating department is in most gardens very much occupied at the present time. Where large plants exist in the shape of bushes, not standards, a limited number may be obtained without the intervention of frames or glass houses. This may be done by layering some of the branches that are most conveniently situated and likely to form good plants, at the same time keeping an eye on the future appearance of the specimen. The portion of the branch that is to be buried in the soil must be partially cut through on its underside, the knife brought up for 2 inches or 3 inches, thus leaving a tongue of that length. The cut part of the branch must be covered with soil to a depth of from 4 inches to 6 inches, and held in position by a stout peg or pegs. The fact of bending down the branch will, owing to the cut being on the under-surface, cause the wound to partially open, and this becoming filled with soil will greatly accelerate the formation of roots. It will be necessary to leave them undisturbed for at least two years before separating them from the parent plant, as if severed before they are sufficiently rooted, failure often results. Seeds are available for the increase of most *Rhododendrons*, but in the case of the many hybrid varieties they cannot, of course, be depended upon to produce any particular kind, though, at the same time, all are beautiful. The seed may be sown either when ripe, or, if more convenient, kept in a dry place till the following spring. A good way to raise seedlings is to place some drainage material in a cold frame, then over this is put a layer, some 5 inches or 6 inches deep, of sandy peat, pressed firmly and finished off with a perfectly level surface. A good watering should then be given through a fine rose, and on the damp surface the seed must be thinly sprinkled. It may then be covered very thinly with the same compost sifted fine. All the attention now necessary will be to keep the soil fairly moist and to shade from the sun. When the young plants are large enough, they can be pricked off under the same conditions, and so treated will grow away without check.

PELARGONIUMS, that is to say, those of the zonal, nosegay, and variegated-leaved sections which in some places are so much used for hedging out during the summer months, can be readily propagated now, and if struck thus early will grow into good-sized plants by hedging-out time. This method of increase is very valuable where the autumn stock of cuttings was of limited extent, and also to replenish any losses sustained during the winter. The most successful way is to keep the autumn-struck plants rather warmer for a week or two, when they will push forth new growth quickly, which can be taken off as cuttings, and the fact of the tops being removed will cause the old plants to break out into two or more shoots and thus improve their appearance. These remarks apply more particularly where autumn-struck cuttings are the only available source for propagating from, but where large plants are available, these, if encouraged with a little heat, will yield a good crop of cuttings. A shelf near the glass in a warm structure is the most suitable spot for the cuttings, which, if short, need not have any of their bottom leaves taken off, for in very young cuttings the cut portion of the leaf is apt to decay, but if allowed to remain entire it dries up and may then be removed. Any light compost will do for this purpose, as the cuttings root in a few days, and if potted off quickly establish themselves. This mode is especially useful in the case of the tricolor-leaved kinds, for when required in quantity, however careful one may be, some varieties

are apt to dwindle should the weather be severe, and in that case those that are required can be encouraged to grow early, and thus yield a crop of cuttings. In the case more particularly of the delicate kinds, the small leafy scales that are produced on the stem had better be removed before insertion, as if the atmosphere of the house is in any way moist they sometimes rot and form a seat of decay which spreads to the cutting. These Pelargoniums, unlike most other plants, strike best when in a position fully exposed to the sun. T.

Propagation by roots.—Propagation by roots is a simple and valuable means whereby many hardy plants and also some sub-tropical plants, such as *Aralia papyrifera*, *Wigandia caracasana*, may be propagated for bedding purposes. The best roots for the purpose are those of medium size, neither too strong nor too weak, and care must be taken that they are not of a woody character, otherwise they will be useless. The roots having been selected, procure a few shallow pans, well drained, and fill them nearly full with light sandy soil. Cut the roots in pieces about an inch long, and lay them on the surface of the soil. Cover them with a thin layer of sand, and then fill the pan up with light soil. Some surface the pans with sand, but soil is preferable, because sand drying so quickly is apt to mislead as to the condition of the soil beneath. Place the pans in a propagating pit, but great care is necessary in watering, especially when growth commences, or the young plants will rot off. When root-action has freely started, the young plants can be potted. *Aralia papyrifera* is an effective plant either in pots or bedded out. When lifting plants that have been planted out, plenty of roots are obtainable. I have raised as many as 100 plants from two small pans of these root-cuttings. They were inserted in autumn, and made nice plants the following season. *Bouvardias* used to be propagated in this way, but young growing shoots are now generally adopted. Roots will also answer in the case of *Pelargoniums*, especially the fleshy-rooted Cape varieties. *Senecio pulcher* is a very good hardy plant, and not readily propagated except by division, which is a slow process, yet the fleshy roots, if treated as described, will soon yield a number of plants. By way of experiment, I tried *Nicotiana affinis*, and my bits of roots soon became strong plants. This can be raised easily from seed, but the above-named fact is worth knowing, for if we should happen to have a bad season and not be able to depend on the seed, we have only to pull up the old plants and cut off the roots to get our young stock. Doubtless there are many more plants that may be propagated from roots. The important point is to secure roots of sufficient firmness without being too woody.—A. HERRINGTON.

GARDEN DESTROYERS.

G. S. SAUNDERS.

THE MULLEIN MOTH.

(*CUCULLIA VERBASCI*.)

THE *Verbascum*, or Mulleins, are deservedly favourites in many gardens, as they are exceedingly handsome plants, and deserve to be more often grown than they are, as at the back of mixed borders and in the wild garden they are very effective. A figure of a very fine species, *V. olympicum*, was given in THE GARDEN of 5th February. One drawback, however, to the cultivation of these plants is that they are so often disfigured by the attacks of the caterpillars of the Mullein moth, which not only eat the leaves, but are also very partial to the flowers. The caterpillars are such handsome creatures, that it is a great pity that they have to be classed among the gardener's foes; but it cannot be helped, for they certainly are very destructive; and though I would rather not have mentioned them on account of their beauty, I feel obliged to do so. The moths are by no means remarkable in appearance, and may be found from April until the beginning of June. The caterpillars, which are of a pale greenish colour, strikingly marked with yellow stripes and black spots, may be

found in June and July. They may easily be removed from the plants by hand-picking, as they do not cling to them so tenaciously as some caterpillars do. There is no other way of effectually getting rid of them. If the plants are carefully examined early in June and again later on, the caterpillars may be destroyed when quite young and before they have done much mischief; and though they will be more difficult to find than if looked for when they have grown larger, the trouble is worth taking, as a plant when once freed from them is not likely to be again attacked. Sometimes these caterpillars, like those of various other moths, are found in unusual profusion. They are said to have been found, during the summers of 1858, 1859, and 1860, in extraordinary numbers on Branton Burrows, in Devonshire, where every plant of *Verbascum Thapsus* was covered with them, and that in July ten or twenty thousand might easily have been collected, varying in size from full-grown specimens to those only just hatched.

THE MOTHS may, of course, be caught in the evening in a butterfly net, but unless a person is

Mullein moth and caterpillar. The caterpillar is copied from Kirby's "European Butterflies and Moths."

well practised in the uses of such an implement and knows the moth well by sight, it is not worth while to try and destroy this insect by this means, as probably very few would be caught in the course of several evenings. The moth is about three-quarters of an inch in length, and measures an inch and three-quarters across the wings when fully extended, the thorax and body of a brownish yellow colour; the former is densely covered with hairs, which form a kind of hood in front, and behind the hood a pair of epaulettes; down the middle is a row of very dark brown tufts; the first four joints of the body have each a dark brown tuft on them, and the three last joints are darker than the others, and are of greyish brown colour. The fore wings are of a pale reddish brown-colour, the front and inner margins being of a rich chestnut brown colour; about the middle of the inner margin is a wavy, nearly white, transverse line; the ends of the wings are deeply notched; just inside the indentation is a fine white line. The hind wings are greyish brown, gradually darkening towards the edges, which are fringed, but the fringe is much paler.

THE CATERPILLARS when fully grown are about 2 inches long; they are provided with eight pairs of legs; these are placed one on each of the first three, the sixth, seventh, eighth, ninth, and last joints. The caterpillars are of a greenish white colour; each joint has a bright yellow band extending from one side across the back to the other; in this stripe are a number of black spots, many of which bear hairs; two are placed on either side of the middle of the back; below these on each side are several others, the face is yellowish with blue spots.

When fully fed the caterpillar buries itself in the ground, and forming a cocoon round itself, becomes a chrysalis, in which state the insect remains until the following April or May, when the moth emerges.

ORCHIDS.

W. H. GOWER.

THE AERIDES.

THESE are natives of India and the Indian Islands, with but a single exception, viz., *A. japonica*, which comes from Japan. The genus contains numerous species and varieties, some of the finest being of comparatively recent introduction, and the majority of them are remarkable for their large, graceful trusses of showy flowers, many of which possess a delicate and grateful perfume. *Aerides* are, however, not wholly dependent upon their blooms for their beauty, as their erect habit of growth, and their graceful two-ranked rich green foliage render them quite as effective as many of the so-called ornamental-leaved plants, which have nothing else but leaf beauty to recommend them. The *Aerides* grow naturally upon branches of trees; hence the name Air plants. They cling by their roots, which they spread out into the air, and thereby absorb moisture on which they depend for sustenance. As, however, under glass a sufficiently moisture-laden atmosphere cannot be provided, pot culture has to be resorted to. The following will be found to be a good and well varied selection from the numerous species and varieties now in cultivation, all of which possess beauty of a different character from that of Orchids from the western hemisphere. *A. odoratum* is one of the earliest Orchids introduced to this country in a living state. It was brought from China in 1800; hence it was called a Chinese plant, but we have never heard of its being found in that country by recent travellers. It is a free-growing species, bearing flaccid, strap-shaped leaves, leathery in texture, and pale green. The racemes of bloom proceed, as they do in the case of all *Aerides*, from the axils of the leaves. In the typical form the racemes are short, but in the variety called *majus* they are long, drooping, and many-flowered; the sepals and petals, which are creamy white, are of a wax-like texture, more or less broadly tipped with pink; the lip, which is pink in front, is bent up to and pressed against the column; the side lobes are erect, and there is a long incurved spur. The flowers of this species have a delicious honey-like fragrance, and usually are in perfection from May till July; the variety *purpurascens*, which flowers about the same time, is a more robust grower, and has broader, dark green leaves. Its racemes of bloom are more dense than in the type, through the individual flowers being larger, and the colour is more intense. *A. quinquevulnerum* is a somewhat slow-growing plant. It bears long, strap-shaped, leathery, bright green leaves, which tightly clasp the stem at the base. The flowers, which appear at the end of summer, are deliciously sweet scented, and produced in long,

dense, pendulous racemes; they resemble those of *A. odoratum* in shape and texture; they are, however, larger; the sepals and petals are tipped with rosy purple, and freckled with dots of the same colour; the middle lobe of the lip is rich crimson, the erect side lobes pink, and the spur green. *A. nobile*, which usually flowers in July and August, has about the same habit of growth as that of *A. odoratum*, but its leaves are longer, and it is less branched than that species. The racemes of bloom, which are pendulous, are branched, upwards of 2 feet in length, many-flowered, and very fragrant. The sepals and petals are white, suffused with rose; the side lobes of the lip are large and creamy yellow; the middle lobe being white, freckled with rosy purple; the spur is pale yellow, and is furnished with a few red dots. *A. virens* is a spring bloomer, producing its long pendent racemes sometimes early in April, but oftener towards the end of that month and in the beginning of May. The flowers, which are creamy white, are suffused with a delicate shade of peach, and dotted with purple; the lip is dotted with crimson, and the spur, which is green, is curved upwards. *A. Lawrenceae* blooms during October, November, and December. It is by far the grandest of the section to which it belongs. The first plant of it introduced to this country flowered, for the first time, a little more than three years ago, and its beauty was so remarkable that when offered for sale by auction it realised the large sum of 235 guineas! Its habit, which is bold, is somewhat like that of *quinquevulnerum*, especially in its leaves, which closely clasp the stem at the base. Its racemes of bloom, which are drooping, are densely set with flowers for upwards of 1 foot in length, and very fragrant; the sepals and petals, which are broad, are creamy white, broadly tipped with purple; the side lobes of the lip have the appearance of being puffed out, are erect, and creamy yellow, the middle lobe being fringed and stained with purple. The spur is very large and green. *A. suavissimum* is a variable plant, and produces its fragrant flowers during the autumn months. Its racemes are long and drooping; the sepals and petals, which are white or bluish, are tipped with rose, and the middle lobe of the lip and the spur are soft pale yellow, the latter being rose-coloured at the point. In the above-named species the lip is funnel-shaped and pressed against the column, and all belong to the *A. odoratum* type.

In the following the middle lobe of the lip is flat and spreading. Of this section *A. crispum* may be taken as the type. In this species the leaves are broad and deep green, their sheathing bases being almost black or blackish purple. The flowers, which are produced during June and July, are sweetly scented; the sepals and petals are white; the lip deep rosy pink and fringed. In the variety *Lindleyanum* the flowers are produced in branched panicles; whilst the form known as *Warneri* is much more slender in growth, and the leaves are erect rather than horizontal. Its flowers, which are produced freely during the summer months, are white, with the exception of the lip, which is deep rose. *A. Houletianum*, a rare and beautiful plant, blooms in spring in the shape of a many-flowered, pendulous raceme. The sepals and petals are canary-yellow, and the lip creamy white, stained in front with magenta. *A. japonicum*, which was first introduced into this country about twenty-five years ago, is a dwarf, slow-growing species with short, broad deep green leaves; the racemes, which are drooping, each bear from six to eight or more flowers during the summer months; the sepals and petals are white, the lower sepals being transversely streaked with brown lines.

The front lobe of the lip is spoon-shaped, white, variously blotched and dotted with rosy violet. *A. Fieldingi* is popularly known as the Foxbrush *Aerides*, on account of its racemes of bloom being long and dense. In habit the plant may be said to be handsome, and in some of the varieties the base of the leaves, which clasp the stem, are purplish black. The racemes of bloom are occasionally upwards of 2 feet in length and sometimes branched, and the flowers, which are large, are bright rose, but whitish towards the base, where they are dotted with rose; the lip, which is ovate and tapering to a point, is bright rose; the column is curiously beaked, and bears a striking resemblance to a young pigeon. *A. falcatum* is a very distinct kind, owing to its peculiar blue-green foliage; the racemes, which are pendulous, are many-flowered, and produced during summer; the sepals and petals are white, freckled with crimson at the tips; the lip, which is large, is crimson in the middle and white in front, faintly barred with rose. *A. affine*, a graceful plant, produces during May and June somewhat erect, densely-flowered spikes of pink and white flowers, spotted with rose. In the variety named *roseum* the racemes are much branched, and the flowers deep rose, profusely spotted with purple. *A. Veitchi* strongly resembles *affine* in habit. Its racemes are very long, much branched and drooping; the flowers are not large, but closely set on the racemes. The ground colour is white, suffused with rose, and dotted with rosy pink. It blooms in July. *A. Lobbi* belongs to the *affine* section, but may be easily distinguished from that species by its broader and closer set leaves, which, moreover, are dotted with dull purple. It produces branching racemes nearly 2 feet in length, densely covered with flowers, which are white, more or less heavily suffused with bright rose, and the lip is violet. It is a summer bloomer. *A. crassifolium* flowers in spring and early summer, and is a Burmese plant of great beauty, but slow in growth; its racemes, which are, as a rule, about double the length of the leaves, bear numerous large flowers, which yield a very grateful perfume; the sepals and petals are purplish rose, and the lip is rich amethyst-purple. *A. Schroederi*, which was introduced into this country from Bombay some years ago, is supposed to be a natural hybrid between *A. crispum* and *A. maculosum*; one plant only of it has as yet been introduced, and it was bought by a Mr. J. H. Schroeder, of Stratford Green, after whom it has been named. In habit it somewhat resembles *crispum*, but the leaves are longer and not so horizontal; the flower-spikes are semi-erect, much branched, and bear numbers of large, handsome flowers, the sepals and petals of which are white, tinged with lilac, and dotted with rose towards the tips; the lip, which is large, is rosy magenta in front, and the spur yellowish green. It blooms during June and July.

The smaller-growing *Aerides* may be managed successfully in baskets suspended from the roof, but we prefer pots for the others. Large pots should not, however, be used; in fact, the majority of Orchids appear to do best in shallow ones. It is now more than twenty years ago since we commenced to use shallow pots for these plants; the special advantages claimed for them were reduction in the quantity of charcoal, potsherds, and other drainage material used; lightness, enabling them to be more easily removed from place to place; and an improvement as regards the general appearance of the collection through half the red pot-surface being removed. These shallow pots, however, did not find favour at that time, but we see lately that they are coming into use again. *Aerides* require more heat all the year round than *Odontoglossums*,

Masdevallias, and other plants that are grown at greater elevations in the western mountains, yet they do not need the enormous amount of heat and moisture that was at one time considered to be necessary for them. The majority of East Indian Orchids, and *Aerides* in particular, thrive well during winter in a temperature of from 60° to 65°, and during summer from 70° to 75°. This will naturally rise higher with sun heat, but that does not matter provided there is an abundant supply of air; at the same time the atmosphere must be sufficiently moist to prevent the hot air from injuring the roots. Pots for *Aerides* should be well drained, and the best material for holding the plants in position is sweet and living Sphagnum Moss. During the growing season—spring and summer—an abundant supply of water is necessary for their full development, but after that time they require rest. In a natural state this is oftentimes a severe trial in the case of these plants. Under cultivation our experience goes to prove that good results may be obtained by reducing the temperature and judiciously withholding water so that the plants may have entire rest, but the leaves should not be allowed to shrivel. As spring returns a gradual rise in the temperature and a corresponding increase in the way of water will start the plants into fresh growth and flower, and when this is attained, carefully avoid wetting the blooms, for upon this depends whether they remain in perfection for a long or short period, and at all times of the year a sufficient command of the temperature should be kept to allow of air being freely admitted. An exception to the rules just laid down for temperature must be made as regards the species from Japan (*A. japonicum*), which we have found to grow and bloom well in the *Odontoglossum* house suspended near the glass.

Odontoglossum Ruckerianum.—This fine Orchid is figured and described in Veitch's "Manual of Orchidaceous Plants." It is now in flower with Mr. Pollett, at Bickley. One plant has produced two spikes from the same bulb, and on the two spikes there are thirty-three flowers. Mr. Pollett also possesses a fine form which has been named *O. Ruckerianum insigne*. There are several varieties, varying but slightly from the form that first flowered in Mr. S. Rucker's garden at Wandsworth. The flowers open with a yellow ground, subsequently changing to creamy white.—J. D.

Odontoglossums.—"C. A. B." (p. 199) does not state what kind of *Odontoglossums* he has attempted to grow; but if they were *O. Alexandro*, his mistake arose in shifting them into the stove. He will find them to do well in a cool house, where the temperature ranges about 50° through the winter. The best compost for them is peat and live Sphagnum, giving them well-drained pots and avoiding overpotting. I would also advise him not to plunge them; they are great lovers of fresh air, and should have copious supplies at all times, but be careful to avoid draughts, and let the air circulate freely round about the plants, and also avoid a dry atmosphere. It is impossible to say anything about the *Cattleyas*, unless something more is known about the treatment they have had.—G. H.

SHORT NOTES.—ORCHIDS.

Odontoglossum Uro-Skinneri.—This is now in flower in Messrs. Veitch's nursery. The lip is blue, slightly shaded, and the petals and sepals pale green, with distinct brown markings. The great peculiarity of this variety is the long time during which it continues to bloom, it having been known to be in flower for six months.

Odontoglossum Wilckeanum is now producing a handsome branched flower-spoke with thirty-five flowers on it in Mr. Pollett's collection. This is most probably a hybrid between *O. crispum* and *O. luteo-purpureum*. The sepals and petals are sulphur-yellow, blotched and spotted with reddish brown.—J. D.

Dendrobium Wardianum.—The variety of this fine species called *giganteum* is much superior to the typical

form; its growths are very stout, and often reach 4 feet or more in length. The flowers are also larger, and more fleshy in substance than those of the old variety; the sepals and petals are waxy-white, broadly tipped with magenta; the lip is of the same colour, but stained at the base with orange, and blotched at each side with velvety crimson. Hundreds of plants of this *Dendrobie* are just now opening their flowers at Mr. Low's nursery at Clapton.

Cypripedium villosum aureum.—This distinct and pretty variety is now in flower in Mr. Measures's collection at The Woodlands, Streatham. Its blooms, which are large, are wholly of a clear, soft canary colour, with the exception of the upper portions of the petals, which are chestnut. Its beauty is enhanced by the polished or varnished appearance which is characteristic of the flowers of the typical plant.

Scuticaria Steeli.—This singular Orchid has been in flower for the past fortnight in the Orchid house at Kew. It has several rhizomes, which are conspicuously marked with membranous rings at short intervals. From the tips of the rhizomes arise the long whip-like leaves peculiar to this plant. In this particular case they have attained a length of about $4\frac{1}{2}$ feet. They are about as thick as a good-sized goose-quill, round, and channelled on one side. The scape bears a single flower, the sepals and petals of which are of a pale yellow colour, copiously dotted with chocolate. The large tri-lobed lip is creamy white, the front being beautifully striped with violet, while its base is ornamented with a bright yellow crest. This *Scuticaria* is a native of British Guiana, where it grows plentifully in some districts. *S. Hadweni* is the only other species at present known belonging to this genus, and it may be distinguished from *S. Steeli* by its shorter leaves and brighter flowers.—A. Z.

FERNS.

W. H. COWER.

SELECT VARIETIES OF PTERIS.

THIS genus, according to old authors, originally contained a vast number of species, many of which, however, after careful examination have been removed to other genera, whilst not a few have been found to differ only in name. The majority of Pterises are tall-growing plants, their fronds when fertile being ornamented with marginal lines of brown sori. Many Pterises are coarse and common in appearance, but some, such as *P. cretica*, *tremula*, *argyrea*, and *serrulata*, are largely grown to supply the London markets, a sure indication of their popularity. The few species enumerated here will be found well deserving the attention of Fern-lovers. *P. heterophylla* is an elegant little stove Fern from Jamaica, which seldom exceeds 6 inches in height, and when bearing its sterile and fertile fronds together it is not, at the first glance, so very unlike robust examples of the Parsley Fern (*Allosorus crispus*). The fronds, which are ovate, are usually twice-divided, and the small segments are stalked, mostly opposite, smooth, and pale green, those on the sterile fronds being serrate at the edges. In addition to this small form, however, we have a plant of the same Fern from Jamaica, in which the sterile fronds are nearly 10 inches high, and the fertile ones 14 inches. This form is very handsome, not at all delicate, and, if properly cared for, it may be grown in a Wardian case. *P. Kingiana*, from Norfolk Island, a noble Fern, assumes a beautiful appearance in about a couple of years if planted out in the rock garden. It must, however, have a cool position, as too much heat speedily disfigures it. It has a creeping root-stock and bears broad fronds some 3 feet or more in height; these are bipinnate, the ultimate segments being large and vivid green; the sori, which only extend about a third of the pinnule, are bright brown and very conspicuous. *P. crenata* is another slender and distinct plant well adapted for Wardian-case culture. It has smooth, twice-divided fronds some 12 inches or 18 inches high; the pinnules, which are narrow linear, are acuminate in shape, deep rich green,

and heavily bordered on the under margins with bright brown sori.

P. arguta, from Madeira and the Canary Islands, thrives admirably in a cool house, and with a little care always produces a cheerful and pleasing effect; the fronds, which are massive, are from 3 feet to 5 feet in height, deltoid in outline, and about three-times divided, the last divisions being large and decurrent. *P. tricolor*, a supposed variety of *aspericaulis*, is one of the most beautiful of coloured-leaved Ferns. It is a native of Malacca, and requires stove treatment, but even then it is not the easiest of Ferns to maintain in vigorous health; we have found it to thrive best when kept in small pots and somewhat root-bound. It enjoys strong heat and moisture and exposure to bright light, though not to full sunshine; the fronds in vigorous plants grow about 2 feet high, but they are often not half that height. They bear about two pairs of pinnæ and a terminal one, all of which are deeply divided or lobed; the fronds when first expanded are bright rose, and have a central stripe of white. These colours they retain for a few days, when the rose gradually changes to deep reddish brown, and eventually bright green, the central white band being retained. *P. cretica albo-lineata* is another variegated Fern, which in general outline resembles the type. In the sterile fronds the pinnæ, which are deep green, are furnished with a broad central band of silvery white; the fertile fronds differ from the others in having the segments long and linear with smooth edges, the others being toothed. This variety came originally from Java, and was at first supposed to be a stove plant, but soon after its introduction it was found to be very common in Japan, where there is little doubt the Dutch obtained it and sent it to their garden in Java. It makes a handsome window plant, has a fine effect when planted out in a cool fernery, and may be used with advantage in a Wardian case. Another variegated Fern is the variety of *P. quadriaurita*, called *argyrea*, a kind which produces a striking effect when planted out in a fernery raised a little above the common level. Its fronds are from 2 feet to 4 feet in length, and from 1 foot to 2 feet in breadth, all the segments being lengthened out into narrow tail-like points. In colour it is a brilliant green, and it has a very broad central stripe of silvery white on each segment. It is of robust and vigorous growth and largely in demand in all the flower-markets. It comes from the hilly parts of Madras. *P. sulcata*, a tall, handsome plant, produces fronds about 3 feet high and bears some ten or twelve pairs of pinnæ and a terminal one; these divisions are again deeply divided or lobed, the lower ones having each a pair of smaller pinnæ on the outer edge (bipartite); the colour is brilliant deep green. It comes from Jamaica. *P. scaberula* is a spreading, low-growing Fern, from the creeping rhizomes of which ascend a profusion of fronds, which are somewhat triangular in outline, from 12 inches to 15 inches long, and many times divided; the segments, which are narrow linear, are rigid in texture and bright green. In this country it seldom bears fruitful fronds, but in its native home it appears to seed freely, the sori being bright reddish brown. It comes from New Zealand, and is almost hardy; it looks well on a projecting boulder in a cool house, and it also thrives admirably in a Wardian case. In *P. semi-pinnata* we have not only a beautiful, but a singular plant, the fronds of which are erect, borne upon black foot-stalks, and usually about 2 feet in height. They are pinnate and rich green, the pinnæ being lobed, or again divided, on the lower side only (semi-pinnate). It is a native of the Philippine Islands and requires

stove heat. *P. aspericaulis* is a compact-growing stove Fern, the fronds of which are pinnate and from 12 inches to 18 inches high; the footstalks, which are red and rough, bear about three pairs of deeply lobed, bright green pinnæ, the lower pair being again divided on the lower edge (bipartite).

Pterises are for the most part easily cultivated; the soil for strong-growing kinds should consist of equal parts peat and loam, with an admixture of sharp sand; the smaller kinds thrive best in a lighter compost. Like all Ferns they enjoy copious supplies of water, to which may occasionally be added a little soot, which tends to intensify the rich colours of their fronds.

SHORT NOTES—FERNS.

Nephrolepis rufescens tripinnatifida.—This variety, which is tall and vigorous in growth, has fronds from $1\frac{1}{2}$ feet to 2 feet long, the pinnæ of which are very much cut. When seen in a mass it has a light and elegant appearance, and in a small stove ought to commend itself to market growers. As a basket Fern it is also very useful. A first-class certificate was awarded it when shown 1st year at the Live pool Exhibition.

Making albums for Ferns.—Having made several handsome Fern albums, I can answer "F. C." Any good-sized album with white paper will do. The Ferns should be picked when the fronds are well grown, placed between blotting paper under a weight for some days, and starch is the best thing for pasting them into the album. Moulding is difficult to make adhere, and can be done best by rubbing with a small brush the starch first on the paper.—MAY BLOSSOM

A note from Mr. Gilbert.—I am waiting to show round the Earl and Countess of Rosslyn, and I cannot employ my time better than in giving you a bit of my mind. In the first place, you tell the public I should raise young seedling Apples, and get varieties to match the American. You do not say as much, but I read between the lines that you mean as much. Let me tell you I have been raising Apples for twenty years, but, unfortunately, have not yet got a good one. At the Great Apple show I picked out two varieties out of \$000 dishes which I thought the best, ordered the trees (eight) at 7s. 6d. each, but these were reported sold! I write to let you see I am preaching progress. I will send you a dozen seedlings by post. Now, I hope in the next issue of THE GARDEN that you will put me on my merits. Do not let it be said I raise Cabbages alone. If you could only see my houseful of Harbinger Primroses you would say and think differently. Next week I am going in for Peaches outside that nobody appears to grow. Depend upon it this is a matter of over-building Peach houses, exactly the same as in the case of Melons. Nobody can grow Melons now in frame frames, because they have houses!

* * An interesting and suggestive note, as most of Mr. Gilbert's are. We are glad to hear of all his doings. Peaches out of doors and Melons in frames are, we hope, not to disappear from our gardens, of which they were once the pride. The last time we were at Burchley we saw good Peaches on walls there. The place is not nearly so favourable for that fruit as many districts in the south and west of England.—ED.

Peat Moss litter as manure.—Perhaps some of the numerous readers of THE GARDEN will be kind enough to give me, through its columns, the benefit of their experience as to the use of farmyard manure in which one of the component parts is peat Moss litter instead of straw. I am told that it will not do for plants that are liable to be injured by cold, as the peat will attract the frost. The litter, I think, ought to make superior manure to straw, as being extremely porous, it absorbs all the liquid, which usually runs away. It also has the advantage of being cheaper than straw.—F. R. II. S.

Names of plants.—H. A. W., *Sagolla*.—*Cypella carulea*.—L. N., *Rhyn.*—1, *Phalenopsis Schilleriana*; 2, *Vanda tricolor insignis*; 3, specimen withered; 4, *Bromelia*.—H. B., *Chipping Norton*.—*Dendrobium chrysanthum*.—*Andromeda*.—Apparently a *Sisyrinchium*; specimens too much shrivelled to identify.—L. G.—Violets are usually bunched in dozens, i.e., a dozen flowers in the single bunch, and a dozen single bunches in the market bunch.—E. Brownhill, *Acaena pubescens*; it is a small flowered species; Messrs. Low, of Clapton, will no doubt be able to supply it; others next week.

WOODS & FORESTS.

"YORKSHIREMAN."

FORESTRY NOTES.

THE CHARCOAL TRADE.—I see a correspondent inquiring about the disposal of his timber for making charcoal. I fear he will have little chance to sell it for that purpose if he is far from manufacturing towns. In the steel and iron trades a large quantity is used, but, owing to the depression of trade these last few years, the demand has fallen off to such an extent, that foresters find it difficult to dispose of cordwood to charcoal-burners except at very low prices, and the timber must be near the towns to reduce the price of carriage. Vendors of timber who are unfavourably situated in these respects will therefore find it difficult to trade on any terms. Some years back, in the iron manufacturing districts, vast quantities of charcoal were consumed, and it then paid to cut and rank cordwood and sell it by auction or tender, in woods not too distant, but now it is not considered worth while to cut and rank it, and in some instances it has been almost given away to burners, just to get the ground cleared. Oak and other hardwoods are preferred for charcoal. For all that it fetches at any time, I doubt if it be worth while allowing the cordwood to be removed from the wood. The removal of the timber must impoverish the soil very seriously, and the tops might well be left to till the ground. The manuring of woodlands is a subject that has never given foresters much, if any, concern, but no one can deny the impoverishing effects of reaping repeated crops of heavy timber from the soil generation after generation. There are woods in England from which crops of timber have been taken regularly for long periods, and in some cases the impoverishment of the soil is visible in the poor condition of the young plantations, that have been put back in their places without any addition to the ground in the shape of manure. I daresay the manuring of woods is practically out of the question in the ordinary sense of the word, although the beneficial effects of top-dressings to the roots of timber trees is well known to gardeners; but still there is no need to aggravate matters in plantations by the removal of tops and branches, which should be left except where they have to be removed for special reasons, such as the attacks of insect pests and diseases.

BOLE & TOPWOOD.—The conditions that produce these separate portions of a tree are quite different, and an intelligent appreciation of this fact lies at the bottom of the successful culture of trees for timber. Comparatively, the branching top of a tree is worthless, and if this had been realised in times past, our hedgerows would not have been encumbered with trees, to the detriment of both the landlord and the tenant. No doubt it was ignorance of vegetable physiology and arboriculture generally that caused our forefathers to plant and preserve so many hedgerow trees, in the conviction that they were thereby "killing two dogs with one stone," by getting a crop of timber and a farm crop off the ground at the same time. On many estates great care was taken of the hedgerow timber. Where the fields are large they do not do quite so much harm, but where the farms and the fields are small, they are positively destructive to good farming of any kind. Under any circumstances, the trees themselves never produce either as useful timber or as much of it as they would do if planted by themselves on a less piece of land in the form of a plantation. I have calculated from the most reliable data gained on the estate that the whole of our hedgerow timber is not at the present time worth half the same number of good plantation trees of the same age and kind. Nor has it ever been different, while the farm lands have been reduced in value by the presence of the trees and brought less rents than they might have done. In the case of some falls of hedgerow Oak and Ash set out during the past few years and sold standing, the tops were about equal to the trunks in their cubic contents

or more, but where a trunk would perhaps fetch 10s. or 20s., the tops would not realise above a shilling or two. In one case the tops of over 700 trees were sold to a charcoal-burner for £15, on condition that he would clear the ground according to contract and get it off the farms. These tops were rough limbs fit for nothing but cordwood; but had the trees been grown in a plantation they would have had trunks, and been worth perhaps some hundreds of pounds. Do as you will with hedgerow trees, or trees isolated anywhere, they will develop an immense head of far-spreading limbs and a short, rough trunk, and when felled the first count for almost nothing. The Beech affords a fine example of the behaviour of trees under such conditions. I am acquainted with some of the fine park specimens in Scotland that have been so often described and praised for their wonderful dimensions. As timber trees they are the worst examples to be found, having short trunks, the tops of which you can almost touch with your hand, and a whole canopy of limbs and branches fit for nothing much except firewood. We know of other plantation examples with trunks straight and clean, and running up to 60 feet in length, that as timber trees drive the park specimens into insignificance, although perhaps half the age. It is bole or trunk we want in timber trees, and foresters cannot be too strongly impressed with the fact that the conditions that produce useful timber of that kind only exist in plantation culture judiciously managed.

RED OAK.—What causes old Oak timber to become red? All old Oaks do not become red, for we have seen plenty of trees hundreds of years of age that were just the natural colour, while other trees of the same age were as red as mahogany. I saw a tree in a woodyard lately of this colour, sawn up into 4 inch planks for furniture purposes, and which would fetch an exceptional price for doors, wardrobes, wainscoting purposes, and the like. For any purposes requiring strength it is useless, being very tender, though not rotten. There were plenty of old Oak trees in the yard that had been felled because they were dead-old or dead, but this was the only red one in the lot. Brown Oak is much commoner, and trees vary in the shade of colour greatly, but the ordinary colour of Oak timber is a lightish brown.

PINUS PONDEROSA.—This Pine is praised at page 201 for withstanding the "keen searching winds from the Atlantic Ocean," but that is not a very great recommendation, for, as a matter of fact, the Atlantic winds, although boisterous, are neither "keen" nor "searching," and there is no aspect more favourable to the Conifer tribe in this country than the Atlantic seaboard, barring gales that blow the trees down altogether. The fine Conifers at Castle Kennedy, the magnificent Spruce woods in the west of Scotland, and many other examples between the Western Isles and the Land's End all testify to this. Hereabouts, inland, with an eastern exposure subject to really keen searching east winds, compared with which the worst Atlantic winds are "balmy gales," the *Pinus ponderosa* makes just a scarecrow skeleton, and cannot be said to be either useful or ornamental, and I fear it behaves in the same way in many other situations. Some of the other Firs, notably *P. excelsa*, *Laricio*, *austriaca*, the *Deodar*, and others, beat it for bulk of timber and height in the same time. My conviction is that the whole of the Pine and Fir tribe should be divided into two sections, viz., those that prefer a dry keen atmosphere, and those that prefer a damp climate. The first suit our eastern seaboard and high-lying, exposed situations, and the others the moister west coast. If your correspondents would give you a list of the species that thrive best in these situations, I am sure it would be useful.

PROFITS OF UNDERWOOD.—I agree with the remark made last week on this subject, that these are not much, except in a few parts where there is a special demand for underwood, for the demand is by no means general. Underwood is the product of "cultivated" plantations and game-preserving, and would find no place in woods in which

the trees were left to grow as thickly as they should be. I notice that whenever the timber is thick and regular on the ground there is no underwood worth speaking of. It only thrives where the timber is thinner than it should be, and represents poor timber culture. The editor speaks of £5 an acre for underwood; it is long since that amount was got here, or anything like it, and for some years back it has been the custom in setting out timber in our older woods to reserve the underwood.

Preparing ground for planting.—Will you kindly give me your opinion respecting the following matter? My employer has a piece of ground on some property at a distance, on which about forty years ago Scotch Firs were planted. These have reached their best and are now decaying. The soil is black, but not boggy. My employer would like to plant forest trees of some kind again on the same piece. I recommended grubbing up the old trees and trenching the ground; unless this is done it will be useless to plant trees of any kind with any chance of success. But I am told that the price of timber in that part is so very low that the expense of grubbing and trenching is considered too much. Then, I say, if planted with undergrowth, such as Laurel, Rhododendron, &c., these may succeed, but such good results must not be expected as those from properly cleared and worked ground. Do you think any forest trees would succeed planted among the old roots of Scotch Fir? and if so, from what kinds do you think that fairly good results might be expected if planted with undergrowth under the same conditions?—S. N.

* * * We are sure that some of our readers will help "S. N.," but we may say that it is possible to go to too much expense in draining and trenching—that is to say, if the great cost of such labours be considered in relation to the probable result. We have no doubt ourselves that by changing the kind of trees a fair result might be got without any expense of turning over the ground; otherwise, how would all the great woods of the world that have never been drained or trenched exist? By far the most beautiful woods that we have ever seen are those that have never been planted by man. Of course, if people have unlimited means and choose to grub ground at the rate of £15 an acre (which is sometimes more than its freehold value), they are within their rights in doing so. Merely grubbing woodlands 1 foot deep and clearing out the stumps have cost us this year over £14 an acre. If we had trenched the ground the cost would have been much greater. A simpler way must be found for doing the work.—E. H.

Abies polita and brachyphylla.—Of these two Conifers the latter is with us by far the faster in growth, and is likely to be a decided acquisition. A young tree planted in 1883 has done remarkably well, and has made in the four years a growth of 6 feet, and also keeps well furnished as it increases in growth. I shall watch its progress, now that it is thoroughly established, with considerable interest, as, judging from last year, it should make a yearly growth of from 18 inches to 2 feet, and if it will do this it will soon develop into a good specimen. Our tree is in a very light loam, with a rather damp subsoil, and enjoys a warm and well sheltered situation. *Polita* does not make anything like this annual growth, but will doubtless make in time a handsome tree. It is very dense in habit, and even more stiff and formal than *Pinsapo*.

Steaming timber.—Careful observation of the quality of timber before and after steaming, and also after bending, reveals the fact that a change in the nature of the wood takes place. For instance, take a piece of green timber and you will find it will split much easier than when dry; you will also find that you can saw it as easy again green than when dry, and the former will warp much more than the latter. By the process of natural drying the sap stays in the timber, and the drier the wood gets the harder it becomes. Many concede that when green timber is steamed it loses much of its strength, but that when steamed and bent partially dry it is much stiffer than

green bent timber. We do not know for certain the quality of the timber in this case, but experience teaches us that thoroughly drying, after steaming and bending, renders it exceedingly hard. As an instance, bent-back corner pillars, when thoroughly dried, are very hard, much more so than they would have been if the wood had not been steamed. This same fact we have observed in rims. One feature with wood naturally dried is that it is less liable to warp or twist than when steamed; we do not refer to bent pieces, as all know that they will twist in all changes of atmosphere; it will warp somewhat, but not as much as the steamed wood. We have had dried Oak timber at least 200 years old taken from the joist of a building, from which we made a straight-edge and square, with the hope of its keeping true, but it warped out of the straight line the same as other dried timber but a few years old.—*American Monthly*.

THE PROFITS OF UNDERWOOD.

A "KENTISH MAN" (p. 201) is a lucky fellow if he can "realise" all of which he writes in his article. Had he put it in the past tense, or dated it ten or more years back, one would not have read with open mouth and envious spirit. If he ever succeeds again in getting £60 for an acre of Chestnut ten years old, we hope he will not keep his good fortune all to himself, but will let us know where it is to be done. The reason of the fall in price for underwood is not hard to understand. For many of the uses to which it was once invariably put it is now no longer required. Long hoops used to be most profitable; now-a-days they come from the iron mines instead of the woodlands, and the dealers are scarcely able to find any sale for them—at least, at a price which will cover expenses. Charcoal does not pay; ditto powder-wood or toywood (before long, even Pea-boughs and Bean sticks will become perhaps things of the past); and in this neighbourhood not only have all the brick-kilns been altered to burn coal, but almost all the cottage grates, too, so that rough fagots are going "for a song." Near the large Hop gardens things may not be so bad; but we have all heard a good deal about foreign Hops and also railway rates, and it does not entail a great mental strain to discover one of the consequences. The chief value of these Kent and Sussex underwoods, which are often so fair to look upon, lies in the employment they afford through the winter months. When the summer and autumn work is over, the men go "into the woods" to work, often with their families as described, and, what is more, when they come out again they always appear more regularly than clockwork even, for that sometimes breaks down, every evening on their way home with a fagot carried perched on a stick over their shoulder—the biggest fagot which they can put together, and the largest and longest stick they can find or carry, so that the wife will have no excuse for not baking at home, provided she has, as most of them do, her own oven. One cannot put forward as a general assertion that underwood is an absolute loss to the landowner, for it may be on poor land for which no tenant could be found who would be at all likely to pay any rent; but for the technical uses to which it was once put, the number of which would astonish many people, they have been superseded largely by the inventions of modern civilisation. There is something primitive in the appearance of a colony of charcoal-burners or hoop-shavers, when one comes upon them unexpectedly encamped round their fire, that cannot fail to strike the attention of anyone not acquainted with their ways, but, like most other things primitively picturesque, they are fewer and farther between than one could wish. The editorial note at the end of the article states that underwoods have been selling as low as £5 per acre. I am sorry to be able to add my testimony of having sold this year good long material nine years old at less than this price; but for all this, I should be sorry to live in any county which had not broad hedgerows and frequent woodlands. C. R. S. D.

Sussex.

Conifers in Ireland.—The notes in THE GARDEN on tree growth and forestry are excellent and very interesting. The only way to ascertain the

trees to plant with success is to note by various correspondents the various circumstances which attend in different situations the same trees. I have planted most of the best introductions of late years. They vary greatly; in one place they do well, in another they fail completely. Many refuse to grow where there is limestone in the soil, others when the prevailing south-west wind straight across Ireland from the Atlantic prevails. *P. ponderosa* has not grown at all; *Laricio* and *Cembra* but indifferently. The Austrian and Maritime always well, as do also the Blue Highland Pine, Spruces, and common Silver. Nordmann's Fir does not like very high winds, and the Spruce is decidedly tender. The Douglas is beautiful where there is no limestone, and so is the *Cupressus macrocarpa* slightly out of the wind. Why is the common Larch of a good variety not more usually planted as an ornamental tree? It is charming in autumn and spring. I have introduced it with great effect, and it minds neither the limestone in my soil nor the great winds which blow over the west and centre of Ireland.—BRINSLEY MARLAY.

TRANSPLANTING TREES AND SHRUBS.

IN order to do this work well one requires an intimate knowledge of the special and distinctive characters of trees and shrubs as regards habit, size, colour, height, &c., and it is necessary, moreover, that soil and situation also be taken into consideration. My purpose now, however, is not so much to describe what should be planted in this or that position as to direct attention to the best methods of doing the work and the proper season at which it should be done. In all kinds of ordinary soils generally the best time for planting is considered to be, for deciduous trees and shrubs, the autumn and early spring months, and for evergreen trees and shrubs autumn, winter, and spring. Summer planting is not carried out to any great extent, neither is it considered judicious. No doubt there are many potent reasons why this should be so. One has an objection to see the pleasure grounds in a state of confusion consequent upon planting operations at that time of the year; there is also the liability of the roots becoming dried in transit, as, for instance, from a nursery, and the risk attendant upon delay, the scarcity of water, &c.; with care, however, these are preventable causes. Let us first consider the question of

SEASON.—I am of opinion that in some soils transplanting may be done successfully throughout the whole year; in others autumn, winter, and spring are the best periods; whilst in the summer months and in certain soils the operation is more successful than at any other season of the year. The soils in which transplanting may be successfully carried on at all times of the year are those which are black, rich, and friable, and rich, deep mellow loams. Those which are preferable for autumn, winter, and spring planting are those which are warm, light, gravelly, sandy and well drained, whilst in heavy, wet clay the maximum of success will be attained in summer. This will, on reflection, I think, appear to be perfectly reasonable and natural, the desideratum being to maintain the roots in a healthy condition, heal up the mutilated parts and induce new growth as soon as possible. The conditions of soil and seasons mentioned above will materially tend to produce such results. The following are the results of experience of planting in various soils and at different periods of the year. Conifers, including *Abies canadensis*, *Douglasi*, *Cedrus Deodara*, *Libani*, *atlantica*, *Cupressus Lawsoniana*, *Picea nobilis*, *Nordmanniana*, *Pinus austriaca*, *sylvestris*, and *Thujas*, in rich black soils and deep, mellow loams.—Summer, 2 per cent. died; autumn, winter, and spring, 1 per cent. died. In sandy, gravelly, and light warm soils.—Summer, 28 per cent. died; autumn, winter, and spring, 6 per cent. died. In heavy and wet clays.—Summer, none died; autumn, winter, and spring, 30 per cent. died. It will thus be seen that in heavy and wet clays summer planting was highly successful. The trees transplanted were from 8 feet to 20 feet high, and many had made growth from 4 inches to 12 inches in length; every one was moved with balls of earth varying from a quarter to one ton in weight; an average of a cartload of good soil was put round the roots of each, all were mulched with well-rotted ma-

nure, and an occasional soaking of water given. These trees showed no signs of suffering in either colour or quantity of foliage; indeed, many benefited by the change, and all are in a most promising condition. The reason of success is perhaps not far to seek, the earth being in a warm and moist state, and therefore in a condition most conducive to root formation and nourishment; dull, warm weather is best suited to the operation.

PLANTING IN WINTER, it will be remarked, was a partial failure, and should in all cases be avoided wherever it is desired to move valuable trees; in this instance the soil being cold and wet was therefore not suited to produce new roots. The feeding points rotted, the roots decayed, and no new roots were formed; the whole became attacked as by a contagious disease, and total inaction took place. This was followed by the stems becoming affected, rendering the sap putrid, in which state trees are soon preyed upon by insects, causing certain death. The cause of all this is coldness, excessive moisture, the imperviousness of the soil to air and the dormant state of the sap, which soon becomes incapable of performing its functions. Well drained, sandy, gravelly, and light soils are best suited for planting in autumn, winter, and spring, for the very good reason that they are warmer, better aerated, and not liable to become excessively dry, as in summer. These soils contain but a small percentage of vegetable constituents, and without the aid of moisture in moderate quantities are incapable of producing the necessary nourishment for the formation of rootlets, and consequently are unable to maintain the trees in a growing condition. In summer these soils are too hot and dry for the purpose of transplanting; the roots wither and perish, the foliage becomes deteriorated, a general disorganisation takes place, and even should the trees live, they take some years before they regain their normal condition and become thoroughly re-established. Soils of this description are unsuitable to transplant from, the roots being generally less fibrous, and by reason of their want of adhesiveness it is almost impossible to maintain a ball of earth intact, which is so necessary for success in transplanting trees. I am acquainted with no soils where mulching is so absolutely essential as with these; indeed, periodical mulching is necessary in order to maintain healthy trees and the foliage of good colour; mulching will likewise maintain the necessary degree of moisture.

RICH BLACK SOILS AND MELLOW LOAMS are best for all ordinary purposes, and with the addition of peat and sand may be made suitable for every known tree or shrub. Planting in such soils is most simple, as the most careless planter will generally meet with success. Should soils of this description become impoverished from any cause, as, for instance, the rapid and luxuriant growth of shrubs, or, in consequence of their vicinity to large trees and hedgerows, the most desirable kinds of surface-dressing are well-rotted manure and leaf-mould. In these soils the least disturbance at the roots the better it will be for the shrubs. If the ground is properly trenched before planting, no further care will be necessary in the majority of instances for very many years, except the keeping down of weeds for the first two or three years. Although the practice of pruning shrubs indiscriminately is most injudicious and destroys their distinctive characters and individuality, in rich soils the pruning-knife may in some cases be used freely; this would be the case with shrubs which are desired to produce the maximum quantity of flowers, and which would produce an abundance of foliage only, unless they were pruned and thinned out. Overcrowding in rich soils should be especially avoided, being both injurious and unnecessary. Planting of nursery material should be done as expeditiously as possible after being received, and the same rule applies when transplanting. The practice of laying in by the heels, as it is termed, and allowing trees and shrubs to remain so for any length of time, is not advisable, the effect being that they are compelled to make new roots a second time when once would be more advantageous to them. It is not desirable to plant two or three shrubs together in order to make a mass at once, one well-developed shrub being in every way better than two or more starvelings. E. D.

No. 799. SATURDAY, March 12, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE GARDEN.

T. W. GIRDLESTONE.

HYBRID TEAS.

THERE has been a good deal of discussion among Rose growers of late as to what constitutes a Hybrid Tea, and whether hybrids produced by the intercrossing of a Tea and a Hybrid Perpetual should be classed as Teas or as Hybrid Perpetuals. Some growers have grouped them under the one head and some under the other, and in the meantime in certain quarters the practice has arisen of constituting them a separate class under the name of Hybrid Teas—apparently a logical proceeding, but in reality far less so than would appear at first sight, and open to the great objection of inconvenience.

A term used to designate any class of plants should be exactly defined or definable, but it will be found very difficult to define the term Hybrid Tea so that it shall include just the varieties intended by those who first made use of the expression and no others. Of all classes of Roses that of the Tea-scented varieties is perhaps the most distinct and the most clearly defined. By common consent it has been jealously reserved for the numerous varieties raised without the appreciable interference of other species from *R. indica*, and all of which have a vast number of characteristics in common. The proposal of some growers to include the Hybrid Teas of various origin and mixed race in the class for pure Teas will never be tolerated either by exhibitors or by the majority of those who grow the Tea-scented varieties only to enjoy at home the refined beauty of these most exquisite of all Roses, and as it has been laid down by the National Rose Society that Hybrid Teas shall not be exhibited as Teas, it is not likely that any serious attempt to class them as such will be maintained. It remains, therefore, to be shown whether they have sufficiently prominent characteristics in common to form a separate and clearly definable class, or whether they ought not rather to be included among the Hybrid Perpetuals.

Out of some four dozen so called Hybrid Teas now in existence, the following list includes all those that are worth growing, and gives, in all cases where it has been recorded, their reputed parentage: La France (Guillot, 1867), Captain Christy (Lacharme, 1873; V. Verdier Safrano), Cheshunt Hybrid (G. Paul, 1873; Mdme. De Tartas Prince C. de Rohan), Cannes la Coquette (Nabonnand, 1877; from La France), Reine Marie Henriette (Levet, 1878; Gen. Jacqueminot Mdme. Berard), Jules Finger (Lacharme, 1879; V. Verdier Sombreuil), Pierre Guillot (Guillot, 1879), Camoens (Schwartz, 1881), Countess of Pembroke (Bennett, 1882; President Chas. Lefebvre), Distinction (Bennett, 1882; Mdme. De St. Joseph Engéaie Verdier), Lady Mary Fitzwilliam (Bennett, 1882; Devoniansis V. Verdier), Gloire Lyonnaise (Guillot, 1884; Baroness Rothschild Mdme. Falcot), American Beauty (Bancroft, 1885-6), Waltham Climbers 1, 2, and 3 (Wm. Paul, 1885; from Gloire de Dijon), and W. F. Bennett (Bennett, 1885), said to be useful for forcing as a market Rose, but not valuable out of doors. The three additions for the current season are Attraction (Dubreuil), Mdme. Joseph Desbois (Guillot; Baroness Rothschild Mdme. Falcot), and Mdme. A. Schwaller (Bernaix).

This is the pick of the varieties which raisers have designated Hybrid Teas on the seemingly obvious deduction that a Hybrid Tea is a Rose of

whose parents one was a Tea-scented variety; but if this is to be held as the definition, the class must be allowed to include all sorts of other Roses, which have originated through hybridisation with Teas, such as Bourbons, Noisettes, and Hybrid Polyanthas. These two last classes, however, are justly grouped separately, for the Noisettes are nearly all climbers having very characteristic foliage, and the Hybrid Polyanthas have foliage, habit, and inflorescence very distinct from all other Roses, though the varieties differ little from each other, except in the colour of their flowers. But, again, no such similarity or distinctness of habit is admissible as characteristic of the Hybrid Teas, for a definition wide enough to cover the habits even of the first three varieties in the list would include a majority of the Roses in cultivation, and the same objection applies to the consideration of inflorescence, form, colour, or any other permanent character; the conclusion being that these Hybrid Teas have no definite character sufficiently distinctive to constitute a basis for a separate class.

It will be worth while to notice that, owing to the very various origin of many Roses and to the innumerable crosses that have been effected at different times between species and varieties, that it is impossible to define a Hybrid Perpetual more exactly than as "a Rose of mixed race, that flowers more than once during the season." It will be at once seen that there is nothing in this definition that could possibly exclude the so-called Hybrid Teas, which, in fact are most of them fairly free autumnals; and it may be incidentally remarked that until lately several of these Roses, such as La France and Captain Christy, were always classed among and considered to be Hybrid Perpetuals.

The Hybrid Perpetual class among Roses is what Asia Minor is to the mind of the ungeographical schoolboy—a sort of general receptacle for anything not immediately referable elsewhere—and there is no imaginable reason why it should not be allowed to contain the Hybrid Teas, especially when its inclusion of such varieties as Etienne Levet and others of the Victor Verdier race has never been questioned. For it will hardly be contested that Captain Christy and Lady Mary Fitzwilliam bear a greater general resemblance to Etienne Levet, for instance, than to Anna Ollivier; and if, on the other hand, it be held that Captain Christy is a Hybrid Perpetual, then it may well be asked why Lady Mary Fitzwilliam should be considered something else.

In view of the fact, therefore, that there already exists a definable and universally recognised class of Roses to which the varieties under discussion can be referred, it is obviously not worth while to make them into a separate class, the distinguishing characteristic of which cannot be clearly laid down, and, regarding Hybrid Teas as being in every sense of the word Hybrid Perpetuals, growers may well be urged neither to class them as Teas nor to employ the term Hybrid Teas as a name for a class at all.

If only compilers of catalogues will avoid using the term or the division, and if it is thought necessary to allude to the parentage of any variety to do so in the description thereof, much unnecessary confusion will be avoided; but, especially, no hybrids should be catalogued as Teas, lest an unfortunate exhibitor should find himself disqualified for including in his stand a Hybrid Tea that he had purchased as a Tea; or, worse still, lest anyone who had ordered a collection of Tea-scented Roses should find his Rose-bed, when the blooming time came, marred by the presence of some of the dull red Hybrid Teas which are so little worth growing at all, and are certainly not worthy peers of the most refined and delicately beautiful of all Roses.

The new Rose, Archiduchesse Maria Immacolata, sent out this season by Soupert et Notting, is said to have been raised from Madame Lambert fertilised by Socrate, and, judging from the coloured plate of the novelty in the *Journal des Roses*, it has

the open form and somewhat jagged petals of the latter with the red colour of the former. Like its seed-parent, moreover, the colour is said to be variable, and the freedom of bloom remarkable. That the perfume is described as delicious will not cause surprise in view of the fact that one of its progenitors was that most delightfully fragrant of all Tea-scented varieties Socrate.

MARECHAL NIEL IN POTS.

Good plants of this charming Rose may be obtained on their own roots for forcing next spring in the following manner: In many places old plants of this Rose will now be in flower, and therefore plenty of young wood may be had. Of this cuttings should now be made and inserted in pots filled with a compost consisting of loam, well decayed leaf-mould, and plenty of sand; give them a good watering, and plunge them in a brisk bottom-heat; place a bell-glass over them, and if kept moist and shaded from the sun when very bright they will soon root. When rooted pot them singly in 4-inch pots, using good fibry loam mixed with some spent Mushroom manure; place them in a warm house, and when established give an ample supply of water to encourage growth as much as possible. Do not stop the shoots, but support them on sticks. Some plants will push two shoots, but, as a rule, when grown on this principle and not stopped they only make one long growth. When the pots are filled with roots shift into 6-inch pots; the compost for this potting should consist of rough fibry loam mixed with half-inch bones. After this potting place the plants in the front of a house, and train them up the roof like pot-ives. Keep them well syringed in order to keep down green fly. In July some of the strongest may be shifted into 8-inch pots and kept growing on in heat until August, when they should be removed to a cool house, and finally placed outside in autumn so as to harden their wood well. They may be kept out until frost appears, when they should be removed to their winter quarters. Cuttings struck in March and grown in this way often make shoots 8 feet and 10 feet in length, and as thick as a man's little finger in one season. When grown in this manner and twisted round stakes they make grand plants the following spring for many purposes, for, as a rule, they produce a bloom at every joint. ORTOR.

Rose Captain Christy.—It is surprising to see in Mr. William Falconer's interesting account of Rose growing in America that Captain Christy is not much grown there for cut flowers, because it is "too small for the purpose"! In this country it is one of the largest light Hybrid Perpetuals and is what exhibitors with unpardonable familiarity describe as a "back-row" flower. But probably where such enormities as Paul Neyron command attention and can find a market, the word "large," which must always be only a relative term, conveys a different impression from that generally attributed to it among florists in this country. There seems a prospect of some confusion ahead, from the intimation in Mr. Falconer's article that there are two white sports from Catherine Mermet in existence. No doubt, however, their distinctness will be thoroughly tested before The Bride's double is generally distributed.

Persian Yellow and Harrison's Yellow.—In Mr. Girdlestone's charming notes on the grouping of Roses (p. 190) I am not a little surprised to find this writer preferring the double Persian Yellow to Harrisoni. They are also described as each bearing a strong family likeness. The writer, however, is surely mistaken in stating that Harrison's Yellow is the stronger grower and Persian Yellow the freer flowerer of the two, and for this reason it is recommended that preference should be given to the Persian Yellow. There must be some confusion here; no Rose can bloom more freely than Harrison's, while generally and on most sites the Persian Yellow is considerably the stronger grower. There are other wide differences of habit, size of bloom and perfume between these two Roses which render it very material that where only room can be found for one of these, Harrison's Yellow should be the one selected. In fact, for brightness of colour, profusion of bloom,

and fulness of fragrance, *Harrisoni* is doubtless the first and best of all the yellow Briers, Austrian or other, and is far and away ahead of the double yellow *Per-ian* with its pancake form, and suspicious odour.—HORTUS.

P.S.—As to the beautiful *Rosa macrantha*, I have never seen it perfect except against a wall.

Rose Papa Gontier.—This Rose seems to be working its way into public favour. A correspondent of the *American Florist* says of it—

I went the other day to Mr. John Henderson's place at Flushing to see the *Papa Gontier* Rose. I had heard several good reports of it, but found on examination that none of them did it justice. As a cut flower it combines good qualities; it is free-blooming, fragrant, and of clean, vigorous growth; the colour is brilliant and rich, and each bud has the now necessary appendage of a long stem, clothed with handsome foliage. When this Rose was sent out by Nabonnand, four or five years ago, several of our Rose-growers tried a few of it, but from carelessness or a want of discernment none of them discovered its merits.

SHORT NOTE—ROSES.

Old yellow Rose.—Having seen in THE GARDEN of Feb. 12 a paragraph signed "F. W. Y." asking for the old double yellow Rose, *Lady King* writes to say that she can supply it, and wants to know if "F. W. Y." wishes it sent at once, and to what direction.—Address, *LADY KING, 21, Fitzwilliam Square, Dublin.*

NOTES OF THE WEEK.

Reading Horticultural Society.—The annual early summer exhibition of this society announced for June 22 will take place on June 2.

Double Daffodils.—Mr. Hartland sends us from Temple Hill, Cork, flowers of the double Daffodil called *Rip Van Winkle*, a peculiar-looking flower, and no improvement on single flowered kinds.

We understand that Messrs. Atlee Burpee & Co., of Philadelphia, have opened a branch establishment at 133, Cannon Street, London, E.C., for the sale of American seeds for English gardens.

Amaryllis formosissima.—From Mr. J. Woodbridge, The Gardens, Syon House, we have received boxes of *Amaryllis formosissima*. It is of a remarkably dark scarlet colour and very effective. It also lasts well in a cut state.

We have received from the Director of the Royal Gardens, Kew, "a bulletin of miscellaneous information." It contains a description of *Cape Boxwood* (*Buxus Macowanii*) and the correspondence relating to the industries at the Mauritius.

Evelyna Kermesina.—This somewhat resembles a dwarf *Sorbaria* in its habit of growth. It bears upon the ends of its reed-like stems pendent heads of blooms, each of which is sheathed in a long-pointed, pale purple bract, which is longer than the flower. Of this genus, the only other species which we have seen in cultivation is *E. caravata*, in which the bracts are pinkish mauve, and the flowers orange-yellow. We recently saw *Kermesina* blooming freely in Sir Trevor Lawrence's collection at Dorking.

Single Camellias.—I send you a box of single Camellias. Our collection, which is extensive, contains many very beautiful varieties not common in gardens. They are great favourites with the king and queen.—HENRY KNIGHT, *Chateau de Louken, Belgium.*

* A charming collection, consisting of both red and white single blooms of great beauty and substance. Along with them came also flowers of *Camellia reticulata*, of which we have in our own gardens here and there some grand specimens.—ED.

Winter Aconites and Ajuga.—On the rock garden at Kew one of the prettiest masses of colour is a mixture of winter Aconites and the common purple-leaved Bugle (*Ajuga reptans*). The Aconites are planted in a spreading mass of Bugle, and the contrast of its vinous-purple foliage with the bright gold of the Aconite flowers is charming. It is worthy of imitation.

Seedling Christmas Roses.—I send you a few of my Hellebore seedlings, which I think you will like to see. Two are especially pretty—a very large-cupped white, and a large fimbriated white with spots in the centre. There are thousands of blooms out at present, and every season adds to the variety.—P. H. ARCHER-HIND.

** A lovely assortment both of white and red-coloured kinds—quite as good as named sorts.—ED.

Calliandra Tweediei.—This Brazilian shrub is only to be met with in such gardens as Kew, though it is so beautiful, flowering at a time when the stove-houses are not over-bright with colour. It is one of the multitude of tropical shrubs belonging to the Pea family, though it looks more like a Bottle-brush Tree (*Callistemon*), as the flower-heads are composed of tufts of crimson stamens. The leaves are finely divided like a *Mimosa*; hence it is a very elegant as

well as bright-flowered shrub. It comes from Brazil, and requires stove treatment. It may be seen in bloom in the Kew Palm house.

M. Godefroy-Lebeuf has started a French gardening paper, for which he adopts our own name. "While taking from an English journal, THE GARDEN, its name," he says, "we intend to follow its programme, and we avow that we aspire to its success." We wish success to *Le Jardin*. The old French periodicals, excellent as they are, appeal to but a limited class.

Thunbergia Harrisii.—The extreme beauty of this stove climber was well shown by the fine specimens exhibited at South Kensington on Tuesday from the *Pendell Court Garden*. The large, deep mauve-purple flowers are surpassed in brightness by few other tropical climbers, and as it blooms habitually at this season its value is increased. It is a free-growing climber, just the plant for a large stove where there is plenty of room for the long, slender shoots to extend freely or hang in graceful festoons. It is a plant readily procured at a nursery, and the wonder is that it is not more common.

Alseuosmia macrophylla.—This pretty *Caprifoliad* seems at present to be but little or not at all known, except in a few establishments. A small specimen now flowering in the temperate pits at Kew was obtained a couple of years ago from Mr. E. G. Loder, Floore. It is a native of New Zealand, where, in the form of a shrub, it reaches a height of 7 feet or 8 feet. The plant is glabrous throughout, bearing leaves 3 inches or more in length with an irregularly toothed margin. A dark, shining green on the upper surface adds to their beauty, while the under surface is of quite a dull green colour. The midrib is prominent, especially on the under side. The flowers, which emit a pleasant odour, arise from the axils of the leaves, borne on short peduncles.—A. Z.

Narcissus committee.—Will you allow me to inform your readers, in case they may not have seen the notice, that the meetings of the *Narcissus committee* for this spring are fixed for March 22, April 12 and April 26, when we hope to carry on our work of former seasons. Any objects of interest that may be sent addressed to me at South Kensington in time for one of these days will be cared for and brought before the committee. What we endeavour to do is: (1) to acquire information as to wild and typical species from their habitats; (2) to identify the names of specimens unknown to the sender, and to correct any errors in nomenclature which may occur among those exhibited at the shows of the Royal Horticultural Society; and (3) to pass an opinion as to the distinctiveness and value of hybrid or seedling forms, and, if considered worthy, to register them under distinctive names.—C. R. SCRASE-DICKINS, *Hon. Sec., Narcissus Committee.*

Anthuriums at Burford Lodge.—Sir Trevor Lawrence's garden contains some grand specimens of these plants, to the cultivation of which a whole house is devoted. The kinds grown are chiefly *Andreanum*, *Scherzerianum*, *ferrierense*, various forms of *Rothschildianum*, and others, and the effect produced by their brilliantly coloured spathes is strikingly grand. A *ferrierense* has almost round spathes some 6 inches in diameter and creamy vermilion in colour. With these the heart-shaped, brilliant scarlet spathes of *Andreanum* form a striking contrast. Associated with these are the mottled forms of *Rothschildianum* and the scarlet-crimson *Scherzerianum*, of which there are here numerous improved seedlings. The only want is a few white kinds, of which many fine ones are in cultivation.

The silvery Rhododendron (*R. argenteum*).—One can only get an idea of the grandeur of the great Sikkim *Rhododendrons* as they grow on their native mountains by seeing such noble specimens as those in the large temperate house at Kew. Every spring the rich collection of these shrubs at Kew is one of the main features of the place, for nowhere else in Europe can such large specimens be seen. Already they have commenced flowering, and two or three species are in full bloom; a huge shrub of *R. argenteum* is now an object of amazing beauty. It is between 15 feet and 20 feet high, and carries no fewer than thirty large heads of blossoms. These

heads are some 8 inches through, and are globular and compact, the flowers being numerous. Each flower is $1\frac{1}{2}$ inches across, of a pure ivory white-like wax with a deep stain of crimson at the interior base. The leaves are handsome, being nearly a foot long, proportionately broad, deep green above, silvery beneath. They much resemble those of the *Loquat* (*Eriobotrya*). In contrast to this lovely *Rhododendron* is the rich crimson *R. arboreum*, of which there are gigantic trees, glowing with brilliant flower-trusses richer in tint than that of any other *Rhododendron*. A few days will see other species in bloom, and onwards till May this house will be visited by many in order to see these noble shrubs.

Imantophyllum miniatum.—This is a robust-growing member of the *Amaryllis* family, but, as most of us know, it is neither bulbous-rooted nor deciduous. It produces stout, strap-shaped leaves, arranged in a two-ranked fashion, smooth, and intensely deep green. The scape, which rises above the leaves, bears a dense umbrella-like head of large showy campanulate flowers, which last a long time in perfection. The greater portion of the flower is rich orange-vermilion, but at the base it is yellow. We recently saw several dozens of this plant in the gardens at Park Hill, Streatham, producing a grand effect. There are several forms which differ from each other in size and depth of colour. The genus is also spelt *Himantophyllum* and *Umatophyllum*.

Staphylea colchica.—This plant, a member of the Bladder-nut family, must not be confounded with the genus *Styphelia*, which belongs to *Epacrids*. It is a much-branched deciduous shrub, with bright green leaves and pure white fragrant flowers borne on the points of the young shoots. It forces very easily, and is invaluable for decoration early in the season, a purpose for which it is grown in quantity by Mr. Howe at Park Hill, Streatham, where we recently saw it in great beauty. The plants are grown in pots, plunged in the open air during summer and autumn, but placed under cover before hard frosts set in, and brought into the forcing house from time to time. We also saw this plant in great perfection recently with Messrs. Henderson and Sons, of Maida Vale.

Alpine Primulas.—These being very much in vogue just now, the following note may be of interest. By a recent publication in the *Annals of the Zoological and Botanical Society of Vienna*, a vagueness in the nomenclature of a natural hybrid between *Primula Clusiana* (Tausch) and *minima* (L.) has been cleared up. There are two forms of this hybrid. The one next to *Clusiana* is *P. intermedia* (Portenschlag), *P. Portenschlagiana* (Becker), *P. Floerkiana* (Salzer). The other nearest to *minima* is *P. Wettsteini* (Wiemann). *P. intermedia* was discovered on the Schneeberg, in 1851, by Salzer, and by Portenschlag on the Wildalpe. Since then it was much sought after by botanists, but in vain. On the 10th June, 1885, M. Wiemann, of the Imperial Botanical Garden, Vienna, found it, in company with *P. Wettsteini*, on the Schneeberg, and my head gardener, M. Obrist, on the same day, in quite another direction, near Admont.—O. F., *Lechenhof.*

The weather and spring flowers.—With the exception of two dull days, we have had fifty-three days of more or less sharp frost at night, and bright, stimulating sunshine in the daytime—alternations of weather very destructive to vegetation; flowers in consequence are scarce, and everything is backward. *Iris Histro*, which, as a rule, flowers about the end of January, has only been out two days. *Colchicum luteum*, from the southern slopes of the Himalayas, is, on account of its purity of colour, showier than any *Crocus*. *Colchicum crociflorum*, from Central Asia, white striped with purple, has sent up six flowers, the produce of one tiny bulb. *Bulboodium ruthenicum* both in form and size makes a good companion to it. Its bright starry flowers resemble those of a small *Crocus*; its brilliant magenta-purple colour makes it highly attractive, and when better known it cannot fail to become a favourite. *Muscari azureum*, *Galanthus Elwesi* and *latifolius*, *Leontice Alberti*, and the rare *Coptis brachypetala*, with its quaint white spider-like flowers, complete the present floral wealth of my garden.—MAX LEICHTLIN, *Baden-Baden.*

GARDEN IN THE HOUSE.

A COTTAGER'S WINDOW GARDEN.

It is surprising to see how good a display a cottager who is fond of flowers can make in a very small space and with but few appliances. In the case of the cottage whose summer show of flowers we here engrave, the space is about 6 yards in breadth by 4 yards in depth. This includes a tiny greenhouse, which gives winter shelter to the Hydrangeas, Fuchsias, Geraniums, and other plants that form part of the summer display. A few boards are roughly nailed up at gradually decreasing heights under the cottage window and form a stage on which the plants are arranged with good effect, so as to form a mass of flower, beginning at the ground level in front and gradually rising to the window. Here and there appear the graceful arching sprays of the Maiden's

in the greenhouse without water, and though withered still adhere to the stems. I attribute this to the use of a certain chemical manure that we have been using in a liquid state all the winter. Azaleas are also operated on with grand results, *A. mollis*, &c., keeping cut for over a week. This is no doubt a most valuable discovery made by accident. Yet before I say more on the subject we shall try its effects on greenhouse Pelargoniums during the summer, the latter being so apt to drop their blooms. I have also used it on indoor Daffodils, and with great effect. For instance, *Ard-Righ*, *Tenby*, and others, are now nearly six weeks open, and perfect yet.—*W. B. HARTLAND, Temple Hill, Cork.*

* * * Mr. Hartland will perhaps give the public the name of this precious chemical agent.—*ED.*

Wallflowers for window boxes.—Amongst early flowering plants easily raised from seed none are better than bushy little plants of single Wallflowers; they are very hardy and when kept dwarf by being planted out in single lines early in the sea-

they are allowed to stand for two years, by which time they form handsome clumps, and are available for forcing again.

PROPAGATING.

NEPENTHES.—These will now be actively in growth, and where it is desired to increase the stock, cuttings may be put in either at the present time or later on. The length at which they are taken will depend upon circumstances, some being more vigorous than others; but nothing is gained by making the cuttings too large, as they not only take a longer time to form roots, but are also liable to lose their bottom leaves before they strike, and thus give the plants a naked appearance. The soil best suited for the cuttings is a mixture of fibrous peat, Sphagnum, and silver sand, thus forming a very open compost. From the heavy character of the leaves, the cuttings require to be inserted firmly, and on that account

may be safely put in deeper than many other subjects. The larger ones are better potted like established plants than inserted as cuttings with a dibble, for, by the first-named method, far greater security is attained. A very good mode of procedure is to place a few crocks in the bottom of a small pot, then put in the cutting so that its lower portion rests on the crocks, and then fill the pot firmly with the above-mentioned compost. After this is done, and a thorough watering given, they may be plunged in gentle heat in the propagating house. It will be necessary to keep them in a close case till rooted, and as a moisture-laden atmosphere is very essential to their well-doing, this should be borne in mind in selecting the place for them. The lights of the case must be kept quite close, and the cuttings require to be very carefully shaded during sunshine. One caution to be observed is, that from the top-heavy character of the cuttings they are rather liable to fall over, even if at first fixed securely, and such a thing will often injure the young roots, so that it must as far as possible be guarded against. If fastened to a stake, they are then rendered more secure, but to be effective, the stake used for the purpose should be first placed in the bottom of the pot, then the crocks added, and after that the cutting and soil, so that the stake is in this manner held in its place by all the later additions. Before consigning them to the propagating case, see that the pitchers do not contain any decomposing matter; otherwise, in a close atmosphere this will often cause the plants to decay.

A cottager's window garden.

Wreath (*Francoa ramosa*); *Lilium auratum* shoots up through dwarfier plants, and *Campanula fragilis*, so well grown by cottagers, is in well-furnished pots, sometimes hanging from the slight framework that a thin cotton blind is tied to, in hottest sunshine. The little garden is also full of good hardy flowers, the pot plants being stood between them. A Sweetwater Vine covers the front of the cottage, and *Clematis Jackmanni* adorns the little porch.

Floral gum for fixing flower petals dispensed with.—Have any of your readers used a chemical manure in a liquid state that acts and gives vitality to flowers so as to preserve them in water for a prolonged period after being cut, even in rooms where a fire is kept all day, with gas at night? I have at present some cut blooms of *Geranium West Brighton Gem* actually in this condition for over a fortnight. Some blooms have been also cut and put on the shelf

son, so as not to get drawn up in the seed bed, they make sturdy growths well set with flower buds, and overcome removal about as quickly as any plants with which I am acquainted. We grow the Blood Red and Belvoir Castle Yellow, both of which we sow in March in open-air beds, and plant out the seedlings in lines in any spaces in the kitchen or fruit garden not otherwise occupied. If not required for other purposes they yield a capital supply of flowers for cutting.—*J. G. H.*

Christmas Roses.—These, coming in as they do so usefully for cut flowers, are made a speciality of by Mr. Walker, of Hounslow, who annually forces a great quantity of them in pots and baskets underneath the stages of the houses devoted to Cyclamens. They are all lifted from the open ground about two months before they are required, potted in any ordinary garden soil and placed underneath the stages, where they yield a rich harvest of bloom. After having flowered they are shaken out of the pots, and if need be divided and planted out in rich soil, where

PHLOXES AND PENTSTEMONS, as well as the various Pyrethrums (now such favourites), can be readily increased by division, but in the case of at least the two first named, where a larger stock of any one kind is needed than can be obtained in this manner, the plant which it is desired to increase can be taken into a gentle heat, or even sheltered by a cold frame, in order to cause young shoots to push up quickly, and when long enough they can be taken off as cuttings, and treated the same as Fuchsias and similar things. The entire shoot should not be taken to form the cutting, but a strong eye or two must be left at the base in order to cause other shoots to push therefrom. By these means the second crop is larger than the first, and the early struck cuttings soon grow sufficiently to have their tops taken off and treated as above. In this way a very large number can quickly be obtained from a plant or two. In the case of any that are divided, if they are of a delicate character or insufficiently rooted,

the best results are obtained by sheltering them for a little while in a frame till the roots are again actively in operation. *Chrysanthemums* will now strike root readily under anything like favourable conditions, and on that account many do not propagate till this time of the year, or even later, but, of course, those who grow flowers for exhibition have their plants rooted sometime since. Dibbled into pots, placed in a cold frame, and treated carefully, they quickly root, and may then be potted off. The principal points to observe are to see that the cuttings are clear of aphides before putting them in, and not to keep them too close, as not only may mildew set in, but the future plant is much weakened if kept too close during its earlier stages.

IPOMŒA HORSFALLIÆ, which is such a valuable flowering plant for furnishing the rafters and similar situations in the stove, is a very difficult subject to propagate from cuttings; still it can be easily increased by grafting either on its own roots or on those of the allied *Batatas paniculata*. It is a very simple operation, the pieces of roots chosen being about the size of a straw, with, if possible, a few attendant fibres, while the scion is formed of the point of a growing shoot. The upper portion of the root may be split for a little distance, then the lower part, being fashioned in the form of a wedge, is inserted therein and tied securely in its place. Soft grafting cotton should be the material employed for tying purposes, as any bruise will greatly militate against the chances of success, and, of course, the union should be as complete as possible. After this is done they must be potted, the roots being twisted round in order to allow the point of union to be below the surface of the soil. They must then be placed in a close propagating case, and the success of the operation may be determined when the shoot commences to grow. When this takes place a little air can be given by tilting the lights, and they must be gradually inured to the air of the house. The shoot of the *Ipomœa* used as a scion may be from 3 inches to 6 inches long.

PRIMULAS of the Sieboldi section, of which there are now so many and beautiful varieties, can, of course, be increased by division, but where a greater quantity is required than can be obtained in this way, cuttings of the roots is the method generally employed, and if this is carefully done large numbers can be propagated from even a single plant, provided it is an established one and well furnished with roots. The plant being turned out of its pot and the soil shaken off, all roots that can be spared are taken away, leaving, of course, enough attached to each crown to support it and bring the flower to maturity. The remaining roots are then cut up into lengths of an inch or so, and dibbled thickly into pots or pans of light sandy compost, burying them at such a depth that the upper part of the root is just covered with the soil. They are then treated as seeds, keeping the soil just moist and sheltering them in a frame. Then, as spring advances, clusters of young leaves push forth from the upper part of the root and grow away quickly. When sufficiently advanced they can either be potted off or pricked out in a bed of prepared soil.

CRATEGUS PYRACANTHÆ.—It may not be generally known that this is far from a difficult subject to strike root as cuttings, and plants raised in this way are, in their earlier stages at least, far more prolific of berries than seedlings are. Besides this, cuttings can be employed to perpetuate any superior variety, such as *Lelandi*, seedlings of which are not always equal to their parent. Last summer I was very successful in striking a quantity of these Thorns by the following method. The cuttings were taken in the early part of July and formed of the current season's growth, each being about 5 inches to 6 inches long. The leaves were removed from the bottom portions of the cuttings, and the latter dibbled into pots of sandy soil. Five-inch pots were employed for the purpose, and being drained for one-third of their depth the soil was then pressed firmly in. After the pots were filled with

cuttings a thorough watering was given, and all were then placed in a frame and kept quite close and shaded. The cuttings were watered when necessary, and any signs of decay removed before the sun was very powerful, and with these exceptions the lights were kept quite close. So treated the cuttings rooted before winter, and are now potted into small pots, the intention being to plant them out in about a month. If the cuttings are placed in the open ground the best time for the operation is early in the autumn, and, of course, they need to be much longer than when put in pots and sheltered by a frame. They should be from 9 inches to 12 inches long, of which about three parts must be buried in the ground, and fixed firmly in position in order as far as possible to protect them from cold and drying winds.

FERNS.

W. H. GOWER.

ANEMIA.

THIS genus consists of elegant, compact-growing species, characterised by having free veins, and a thin paniculate fructification on the lateral branches of the sterile fronds. This arrangement produces an appearance like that of a spike of bloom; hence they are popularly known as Flowering Ferns. The varieties of this genus already in our gardens are extremely ornamental, and some of the kinds not yet introduced are even more beautiful. *Anemias*, with but few exceptions, are natives of the West Indian Islands and Tropical America. They thrive in a cool stove and enjoy a moist atmosphere, but dislike having their fronds drenched with water by the syringe. They should be planted in peat and sharp sand, and kept in rather small pots. Thus treated, they form charming stove plants, and are available for room decoration, whilst some of the kinds are suitable for a Wardian case. *A. adiantifolia* is one of the most beautiful, and perhaps the hardest of the *Anemias*, producing fronds from 9 inches to 12 inches long, and from 4 inches to 8 inches in width. They are triangular in outline and three-times divided (tripinnatifid), the segments being wedge-shaped, toothed on the edges and deep green. The fertile branches rise erect in pairs, from the base of the sterile pinnae, to about 6 inches in height or more; these are also three-times branched, the segments being wholly fertile and ferrugineous. It is plentiful in Jamaica and in various other West Indian Islands. *A. hirsuta* grows from 6 inches to 12 inches high; the fronds are once-divided (pinnate), the segments being broad and dentate, and the stems are clothed with short reddish brown hairs. It comes from Brazil. *A. Dregeana* is one of the few kinds found out of the western hemisphere. Its fronds, which are about 8 inches high, are simply pinnate, the segments being entire and deep green. The stems are clothed with short, woolly, brown hairs, and the fertile branches are longer than those that are sterile. It is a native of South Africa. *A. cheilanthoides*, sometimes called *tomentosa*, is an elegant Brazilian plant, the fronds of which grow from 6 inches to 12 inches in length. They are twice-divided, the segments being finely cut, pale green, and furnished with rusty-red hairs; the fertile branches are very conspicuous; they rise from 6 inches to 12 inches in height. *A. collina* is also a Brazilian plant, the fronds of which are from 9 inches to 12 inches high; the stems, which are clothed with bright chestnut hairs, are pinnate, the segments being broad, obtuse, and dull green; the fertile branches are 9 inches high. *A. Mandiocana* is a pinnate-leaved species, the segments of which are broad, oblique, crenate-edged, and bright, shining green; the stems are

clothed with dark brown woolly hairs; the fertile branches rise from 6 inches to 9 inches high. It comes from Brazil. *A. Phyllitidis* and the two following kinds have reticulated veins, and therefore have been separated from *Anemia*, and placed in the genus *Anemidietyon*. *A. Phyllitidis* is a bold, robust plant, with fronds from 1 foot to 2 feet in height and once-divided; they usually bear about 6 pairs of pinnae and a terminal one, all of which are some 4 inches long, and an inch broad at the base, serrated on the edges, and bright green; the fertile branches, which are from 9 inches to 12 inches high, are very dense and bold. In the variety *longifolium* the pinnae are much narrower, and vivid green; the fertile branches are also narrower, but dense, and upwards of a foot high. The variety *fraxinifolium* is very handsome; it grows from 18 inches to 2 feet in height, and bears about nine pairs of sterile pinnae and a terminal one; these are about 2 inches long and an inch broad, crenate-edged, and deep green; the fertile branches, which are a foot high, are very dense. The *Anemidietyons* are very hardy plants, and widely dispersed over Tropical America and the West Indian Islands.

AMERICAN MAIDEN-HAIRS AND WILD FLOWERS.

REFERRING again to two essays on hardy Ferns, in which our North American species are noticed in THE GARDEN of October 2 and 23, I would like to speak of the peculiar beauty of our very common *Adiantum pedatum*. It grows with us in the leaf mould of shady or moist woods, and does well in dense shade, not thriving in competition with Grasses in sunny, exposed places. Its pretty black stem and branches, its horizontal and gracefully-massed fronds, make this plant very beautiful, especially to one familiar with the exotic kinds of Maiden-hair Ferns. Our Maiden-hairs would do well planted below trees and by shady walks in leaf mould, and would take care of themselves in such localities. A good stock could be readily mailed by anyone familiar with plants in this country. Your correspondents do not mention two North American plants which would be pretty planted out for companions to other hardy natives or exotics—our pretty *Trillium grandiflorum*, or Wake Robin, and the *Dodecatheon Meadia*, commonly called Shooting Star. The *Trillium* is a very showy plant, which, in June in rich woods, dots the whole surface of the ground with its showy three-petaled, vase-like flowers. It grows from 10 inches to 18 inches in height, and is one of our most beautiful wild flowers. Plant the tubers, small though they are, about 4 inches or 6 inches deep, as they seem always to occur at that depth or deeper, and you will have no further trouble with them, as they are very well able to care of themselves. They will thrive equally well in shade or sunshine—perhaps better in the sun, but on the bare ground, in the shade of trees, they more readily catch the eye. No more attractive plant could be used among hardy Ferns or fernery rockwork than this. When the Ferns are unrolling their fronds this would be ready to hide their nakedness from the beholder's gaze. The *Dodecatheon* is also a low growing plant. Its leaves make it look at first glance like an *Auricula*, but its flower-spike rises a foot high, and has numerous flowers somewhat like the flowers of *Cyclamen*. It grows and rapidly increases in any situation. It would look well among hardy *Cyclamens*.

CHAS. L. MANN.

** Mr. Mann will, no doubt, be pleased to know that these plants have long been valued in our gardens.—ED.

Alsophila Rebecœ.—This is a very elegant, slender-stemmed Tree Fern of recent introduction, originally discovered in the north of Queensland, in the neighbourhood of Rockingham Bay. Its slender stems attain a height of about 8 feet, and bear numerous arching, deep green fronds some 12 inches

or 18 inches long; these are twice-divided (bipinnate); the segments are large, firm, and leathery in texture, and somewhat obtuse. The sori are usually disposed in two medial rows. We recently saw good plants of this Fern in Mr. William Bull's nursery at Chelsea.

Adiantum peruvianum.—Amongst large, bold-growing Maiden hair Ferns this species stands pre-eminent. We recently saw fine examples of it in the fernery at Beddington House. It grows several feet in height, and the fronds are beautifully arched; the stipes, or stems, are stout and jet-black, and the segments are upwards of 2 inches across, ovate in shape, and deep green. This Fern should receive the attention of those who are about to plant a fernery or have accommodation for large specimens.

FLOWER GARDEN.

SEEDLING AURICULAS.

ONE of the chief charms in growing seedling flowers, and especially seedling Auriculas, is the uncertainty that prevails as to what the seedling plants will be; and so to watch the expanding pips is an occupation of some interest. Seedling-raising gives a good deal of pleasant work to the cultivator. If I can gather seed early enough to sow in August, I like to do so. Time is gained in sowing at the end of the summer, as the seeds germinate, and the seedling plants make some headway before the cold weather sets in. I sow in 5-inch pots, filling them nearly half full of drainage. Over this I place a little Cocoa fibre, and then place at the top of this some rough soil, filling up with a fine, light compost, composed in large part of leaf-mould and sand, with some yellow loam sifted fine. The surface is flattened down, the seeds sown as thinly as possible, a little silver sand placed over them, and they are then stood in a shady part of my Auricula house with a piece of glass on each pot. As soon as the seeds show signs of growth, the pots are stood in pans of water, and then there is no necessity for surface-watering. Before the seeds germinate, if water is required, I immerse the pots in water nearly to the level of the soil, and when the contents are saturated, the pots are allowed to well drain, and are returned to the house.

As a matter of course the development of the seedlings is greatly helped if they can be put in a house all through the autumn and winter where there is a slight and genial artificial warmth. In a cold house the tiny plants are practically stationary from the end of October until the end of February, and then they begin to be active again, and it is during the spring months following the time of sowing that they should be encouraged to grow to their very utmost. To this end, as soon as the fourth or sixth seed-leaves are formed, the seedlings should be carefully pricked off into pots of light, sandy soil previously well drained, and so carefully transplanting as that some soil can adhere to the roots. I find it best to use 3-inch pots for the first pricking off, placing the plants only round the sides of the pots, then giving them a slight sprinkle; they are then stood on a bed of moist Cocoa fibre in the Auricula house, and shaded from the sun where necessary. Unless the plants had the advantage of a little warmth to keep them growing during the winter, they can scarcely be expected to flower in the autumn following, but a good many will the following spring, but much depends upon how they are treated during the summer. About August I pot all the more advanced singly in small pots, to bloom the following spring. As a matter of course it is only from the best varieties carefully fertilised, that one can expect to get something showing first-rate properties.

I have to bloom this spring seedlings from the finest edged and self flowers in my collection, also from alpine, double, and fancy flowers. A few of the alpine and double varieties bloomed late in the autumn, and all those that showed the possession of merit were marked; those of indifferent quality are planted out on a south border in the open ground. This border is raised 6 inches or so

above the ground level, and is edged towards the south with a border of *Aubrietia violacea*. During the summer it is surfaced with Cocoa fibre, and a few pieces of broken pots are laid between the plants to prevent them being injured by cats. A few plants will die during the autumn—fog and frost try them somewhat—but those that bloom are very pretty in spring.

It must not be thought that those among Auricula growers who prefer to cultivate their choice varieties in pots are insensible to the value of the Auricula as a border plant. All who have garden space have their outdoor collection of Auriculas, and the raisers of fine varieties are found advocating that the inferior seedling forms should on no account be thrown away, but be planted in the flower garden. Many a one who has but a small piece of garden ground can grow a few Auriculas in pots in a cool frame, and find in them a great source of delight.

Here, at Ealing, I find the cold, raw, London fogs very injurious to the Auricula. These prevail during the end of November, December, and January, and find their way into the Auricula house, and, despite one's utmost care, plants will die. I find it becoming more and more difficult to winter such sorts as Colonel Taylor, Alexander Meiklejohn, George Lightbody, Victor, and a few others of the highest quality. To do so with anything like safety they must be in small pots, that is, as small as they can be conveniently placed in; the pots must be well drained, and the soil light and composed largely of vegetable mould.

R. D.

Mimulus.—Although seed of *Mimulus* is so fine and apparently liable to injury from cold, yet it germinates very freely in a cool house. Seed sown in pans three weeks since, and stood in a house where there is no heating power, the soil in the pans having been frozen twice since being placed there, has germinated freely, and the soil has now a green aspect. It is so much the practice to advise *Mimulus* seed to be sown in heat, that this capacity to germinate freely without warmth cannot be too well known. A little later the seedlings will be dibbled out into a cold frame, and from this transferred with balls of soil into the open ground. A cool, partially shaded place suits them admirably.—A. D.

Perfume of *Iris reticulata*.—Not the least of the many good qualities of this most useful plant is its delicate perfume which many think is even superior to that of Violets, to which it certainly promises to be a powerful rival. During the warm sunshine, of which we have had a more than usual quantity during the latter half of February, the perfume of this lovely plant was very marked. If its blooming is at all accelerated by heat the perfume is by no means so apparent as when it is allowed to flower naturally. Those who depend largely on cool-house plants ought to cultivate largely this pretty *Iris*, which increases freely, the main point being to treat it rationally after it has done flowering, for if stored away under the stages before it has completed its growth it cannot possibly perfect it for another year. We set ours in a cold frame, or else on a light shelf in the orchard house, and keep them regularly supplied with water until they show signs of going to rest, when they are allowed to become quite dry, in which condition they remain for a month, and are then shaken out and re-potted, as I find they keep better in the soil than in any other way.—J. G. H.

Effect of the winter on Stocks.—Whatever may be found in more favoured localities, certainly in this neighbourhood Stocks have wintered badly; indeed, the Bromptons seem quite destroyed. Possibly in specially sheltered gardens a few may be found alive, but still somewhat crippled. It is very much to be regretted that so much difficulty should be experienced in keeping these very beautiful flowers, but they suffer materially three winters out of every four. I am preserving some choice double scarlet Bromptons in pots in a cool house, but the plan, I fear, can hardly prove satisfactory, as some damp off, and all are of indifferent size, being of necessity restricted in pots. Brompton Stocks, however good the strain, have nothing special to recommend them, unless fine

also; indeed, it is the dimensions of the spikes of bloom which command admiration. Even prior to the advent of the snowstorms considerable mischief seemed to have been done by fogs allied to sharp frosts; indeed, we have no greater enemy to many assumed hardy plants than heavy fogs. From these, as a rule, gardeners in rural localities are naturally exempt. Happily, we can, in the capital white and scarlet intermediate Stocks, have a good show in the spring by simply preserving a few hundreds through the winter in small pots under the protection of a frame. These planted out in sheltered positions towards the end of March will give a fine mass of flowers and enrich the garden with strong sweet perfume.—A. D.

THE DOUBLE PRIMROSE.

IN THE GARDEN of Jan. 22 and Feb. 5, 1887, appeared two articles on that charming little plant, *Primula acaulis flore-pleno*, of which at one time I possessed a very fine collection, and if my experience is of any interest to your readers, they are quite welcome to it. The cultivation of the rarer varieties is at all times attended with difficulties which in some localities are insurmountable. Three things they cannot abide—a stagnant soil, a draughty situation, and constant removal or disturbance. As to the kind of soil in which they ought to be grown, it matters little except so far as colour in the bloom is concerned. It will be observed that if a plant of the common single yellow be taken from the hedgerow and highly manured, it will in a year or two push blooms of a sickly pink or mauve hue, though, strange to say, the reverse treatment does not produce opposite results to any marked degree.

I have grown that most delicate of all the varieties, *atro-rubra* (dark maroon), to perfection on a bank which was as dry as dust, and I have seen it luxuriate under the wall of an old castle, beneath the dark rich soil of whose precincts slumbered many an old Roundhead. When planted in a damp, or what is called a sour soil, the Primrose will as it were endeavour to rise from its bed, and will exhibit rough root-stalks something like those found on an old Seakale stool. This is an infallible sign that the locality is unsuitable. I would not recommend pot culture except in the case of a young and delicate plant, which may require protection at first, but the blooms of these are always inferior; in fact, the Primrose requires three or four years' growth to secure satisfactory results. The greatest enemies of this plant are the wire-worm and the tidy gardener. The old leaves ought never to be removed; they are Nature's protection against sudden changes of atmosphere. To those who are unfortunate as to locality and soil I would recommend a north-east border, not under, but in the shade of trees, and a compost composed of one-fourth silver sand, one-half well rotted stable manure, two parts well rotted leaf-mould, and two parts loam from an old orchard. When planting, the roots should be carefully spread over a little mound below the surface of the bed, then covered and well pressed down.

MOMUS.

The Periwinkles.—"W. G." does well to call attention to these (p. 161). Few plants are more valuable for clothing banks or bare places under trees where hardly anything else will grow. They are well worth growing for their foliage alone, though their flowers are also beautiful. For many positions they are far more valuable than Ivy, as they are by no means such greedy monopolists, though some of the larger sorts will hold their own against all comers, and give less timorous growers but a poor chance where they are fully established. Only a night or so before reading "W. G.'s" article I was called in (in a dream) to give advice about getting rid of Periwinkles in a roseroy. The larger varieties had completely overrun and killed most of the Roses. The roseroy was on a sloping bank near to the drawing-room window, and the Periwinkles looked their best on this incline. I shall never forget the reception my suggestion to grub them up received from the

owners of the garden. "Never," was the emphatic reply; "we may have Roses there; we must have the Periwinkle." The difficulty was surmounted in my dream by placing several earthenware oval jars among the Periwinkles, filling these with rich compost, and planting choice free-growing Tea Roses in the jars, my latest advice to the lady of the house being to let the Roses scramble over the bank among the Periwinkles. I doubt if I could have given better advice or shown better practice if ever so wide awake. A light spread of Roses over a bed of Periwinkles in or out of blossom must needs prove a thing of beauty, if not a joy for ever; and the Roses, with their food safe above the strife and struggle of the Periwinkle roots, could not fail to thrive. Periwinkles also form far safer block or stone clothers in ferneries or wild gardens than Ivies. Such beautifully marked and vigorous varieties as *Vinca elegantissima variegata* speedily cover the bases and lower portions of roots or blocks, while comparatively seldom encroaching much on the plants growing in the upper portions of root or rock masses.—HORTUS.

Spring flowers.—Amongst these nothing is so interesting or so enjoyable as the Wallflower, borders of which edged with lovely Primroses have a grand effect. Wallflowers sown last July or August may be lifted with balls of earth attached to them and planted forthwith. All cultivators of Primroses are aware that in a young state they suffer from full sunlight; therefore we sow them under north walls, and protect them through the winter with Bracken. Walking along by my Primrose beds to-day, I found that they were bristling with flower-spikes, and asking me in a language peculiar to themselves to remove them so that they might have a peep at the sun. All kinds of Daisies should be broken up into single eyes and planted near the edge of borders. Pansies, too, make an admirable show in such positions. These we propagated under hand-glasses, also close to north walls, in July, and they have now grown into nice little plants. They should be carefully removed with a trowel, and after planting shaded if possible. The present time is the best for planting Carnations, Pinks, &c. These plants have been wintered in cold frames in pots, so that they turn out with every root attached to them with perfect safety. If not already done, do not delay planting Rose trees, both standards and dwarfs: if the latter are in pots, so much the better.—R. GILBERT.

Narcissus cyclamineus.—Mr. Wolley Dod is surely right (p. 188) in denying this a place in Ajax or *N. pseudo-Narcissus*. I would go further and say that it cannot be, as has been suggested, a hybrid between *N. pseudo-Narcissus* and *N. triandrus*. It is scarcely conceivable that in such a hybrid the perianth should be reflexed more sharply than in *N. triandrus* itself. I believe that in all known hybrids of *N. pseudo-Narcissus* and *N. triandrus* the perianth, as might be expected, is bent back towards the tube less than the perianth of *triandrus* and more than the perianth of *pseudo-Narcissus*. And if *N. cyclamineus* were a hybrid of *N. triandrus*, it would in all probability sometimes have more than a single flower on a scape. I think that *N. cyclamineus* must be classed alone until some plant akin to it is found. Mr. Burbidge's statement (p. 160), that seed of *N. cyclamineus* germinates in about a month after being sown, surprises me. Seed sown here with all care did not germinate until February—at least, young plants did not appear until then—i.e., was some eight months in germinating. I once knew seed of *Narcissus* to appear above ground in about five months, but, as a rule, my seed lies from about June or July to December. Will Mr. Burbidge kindly give the exact dates, or as nearly as possible, of his sowing this seed and of its appearance, and help me by describing his special treatment?—G. H. ENGELHEART.

Primula obconica.—This little *Primula* is one of the very best that can be grown for furnishing flowers in winter. It has been in bloom continuously since the end of November, and is now,

March 1, quite a sheet of flowers, individual plants having from twenty to thirty trusses. It is alike invaluable for the side stage of the greenhouse, as a small plant for indoor vases, or for cutting purposes. Although it is so hardy and will throw up its flowers in a low temperature, it is, in common with the varieties of *sinensis*, seen at its best with a little extra warmth, and a batch should always be kept in a warm corner to furnish flowers for small vases, bouquets, &c. When once a stock is secured from seed it can be readily increased by division, and I fancy plants obtained in this way flower rather more freely than seedlings. Our plants are shaken out as soon as they have done flowering, pulled to pieces, and potted in small 3 inch pots; they get one shift some time during the summer either into 4½-inch or 6 inch pots as they may be required, and when these pots are filled with roots they receive occasionally some liquid manure.—E. B.

NARCISSUS TRIANDRUS.

The variation of *N. triandrus* in shape and length of the crown and exertion of the style are curious and interesting. The accompanying pen-and-ink sketch (of a single flower from each scape) is from a comparatively small number of flowers sent me by my friend, Mr. Wolley Dod. They were not

Variation of *N. triandrus albus*.

sent in order to illustrate this variation, which could probably be shown to be much more extreme. G. H. E.

P.S. — Since writing the foregoing I have noticed that the flower of *N. triandrus pulchellus*, the variety with yellow perianth and pale crown, is strongly Jonquil-scented; whereas the white or more common *triandrus* is scentless. This leads me to the inquiry whether *pulchellus* may not prove to be a hybrid of *N. triandrus* with *N. Jonquilla* or *N. juncifolius*, and whether I may not be wrong in supposing all *Narcissus* hybrids to be decidedly intermediate in all their features. If one parent, probably the male, sometimes gives colour only, or little modification of form to the hybrid, then *N. cyclamineus* may be the offspring of *N. triandrus* by a yellow form of *N. pseudo-Narcissus*. Moreover, Mr. Wolley Dod informs me that *N. cyclamineus* is not invariably one-flowered. I do not know, however, whether the rare occurrence of a two-flowered scape would tell us anything trustworthy about parentage, for many *Narcissi* which are truly one-flowered, e.g., Emperor, will occasionally produce two or more

flowers on a stem without fasciation. I can find no notice of the habitat of *N. triandrus pulchellus*, but it will be interesting to learn whether *N. Jonquilla* or *N. juncifolius* is found near it.

G. H. E.

LILIES AND THEIR CULTURE.

LILIUM AURATUM.—Must there not be something to be found out about the culture of this Lily, when we consider the enormous quantities of it that are every year imported from Japan, and that are not to be found in gardens in any quantities, except in pots; we cannot therefore avoid asking, Why is this? Other Japan Lilies are imported and seem to succeed, but *auratum* after a year's flowering seems to succumb, so that now, especially for pot culture, growers seem to treat it as an annual, and renew their stock of it as they do that of Hyacinths, never expecting any from it after the first year, and contented if they get a good bloom of it and then let it die; its cheapness also enables this to be done. Good bulbs can be bought in the auction mart for about 2d. each, and do I not recollect the time when Mr. Rucker carried home in triumph the first plant of it Mr. Standish flowered for fifteen guineas. One is at a loss to understand how it can ever pay the Japanese growers to send them over when they are such a drug; when we consider the expense of growing and packing, and freight—no inconsiderable matter—the auctioneers' commission, and other matters, it is a marvel why they export them at all. There is one drawback to the cultivation of this Lily in the open, and that is, that in case of wet or windy weather the pollen is blown or washed off in large quantities on to the petals and disfigures the flowers very much, while, when grown in pots, their overpowering perfume is far too heavy for the olfactory of most people. It is somewhat remarkable that there should be this difficulty about growing this Lily, as it is by the best authorities considered to be but a sub-species of the easily-grown *speciosum*. In its native habitat it is said to be found growing in light, rich soil amongst rocks and under shrubs, and the persons who have been the most successful with it are those who, like Mr. Wilson, Mr. McIntosh, or the Messrs. Walker, grow it amongst their Rhododendrons in the light, peaty soil of Surrey; yet other growers recommend a soil of which three parts are loam, but, after all, I believe that peat suits this, as it does nine out of ten Lilies, best. Many of the bulbs of this Lily instead of continuing solid, "break up," as it is called; the scales become separated, and small bulbs appear at their base. I believe such bulbs are of very little use; they will never again make flowering bulbs, and this is one of the reasons why the imported bulbs fail so. They may, perhaps, receive some injury, or, what is more likely, they resent being taken up and packed up, for I am sure a great many bulbs thus perish. My experience is that they do best when planted deep, provided the drainage is good and so that no water stagnates about the roots; but after all, I do not think that it is a satisfactory Lily to grow out of doors, except in some specially favoured localities.

L. MARTAGON.—While the commoner varieties of Martagon are grown everywhere, there are two which are sometimes considered difficult, and while not so widely known, are perhaps the most striking of the genus—the white and the very dark variety; the former of these is very pure in colour and exceedingly pretty. The finest clump of it I ever saw was in the garden of my friend the Rev. F. Tymons at Drumcondra, in the county of Dublin. A piece of that clump is now flowering in my own garden, and has been greatly admired. It does not seem to require any particular care, and in my rather light and rich garden soil seems to do very well. I have not been so successful with the dark-coloured *L. dalmaticum* or *Catanei*. It is sometimes called the black Lily, but, like many other flowers similarly named, it is really of a dark purple colour.

L. TESTACEUM.—This is one of the most satisfactory and fragrant Lilies that we have, and yet

there seems to be some doubt as to its origin. This I must leave to wiser heads. There seems to be no difficulty in its culture. It succeeds well in my light garden soil, and throws out some grand stems from 5 feet to 6 feet high, with half a dozen or more flowers on each stem of a very bright shade of yellow, somewhat tinged with red. Very pleasing and attractive.

L. CANDIDUM, the common white Lily or Madonna Lily, after being neglected or thought too common for anyone to trouble themselves about, has come into high favour of late years, and various questions have been asked as to the best way of growing it. The only point about which it seems to be particular is, that it likes to be let alone, for, as I have already said, in this neighbourhood it is to be found flourishing in all sorts of situations and soil, in bright sun and partial shade, in light soil and heavy soil; and, therefore, I must conclude there is no real difficulty about it in the southern parts of the kingdom, whatever there may be in the north. I think it is a great mistake to cut this flower for house decoration, for there are some people to whom it is most offensive, and most people think it too strong.

L. SZOVITZIANUM.—A very fine and distinct Lily, sometimes known as *colchicum*, and really a variety of *monadelphum* (so the wise men tell us). It is a very beautiful flower of a pale bright yellow colour, and when well established makes a very handsome clump.

L. FARDALINUM.—There seems to be a good deal of confusion about these North American Lilies, and undoubtedly a good deal of sameness, but most of them are well worthy of cultivation in our gardens, and are of easy culture. The finest clump of this Lily I have seen was in the garden of Mr. E. Harvey, at Aigburth, near Liverpool. It was in a bed with other plants, and had a grand and stately appearance. The same may be said of

L. SUPERBUM, a grand and noble-looking plant when cultivated in low and moist ground, in which it delights, being known as the Swamp Lily. It will not stand in ordinary borders such dry summers as we have had—the last two years have been too much for it in such situations—but where it has had plenty of moisture it has done well. I suppose one must regard

L. MICHAUXII as but another form of this. I received it a few years ago from Canon Ellacombe, and until last summer it did very well, but that was too dry for it, and I have this autumn removed it into what I hope will be a better place for it.

L. HUMBOLDTI is another fine form which, however, I have not been successful with, although friends assure me it is very robust. Most of these Lilies have a great similarity of colouring, although many differ in their markings, and hence, I suppose, the muddle of which some people complain in the catalogues. It is somewhat provoking to get a new variety, and find it to be almost, if not perfectly, the same as one already grown.

L. LANCEFOLIUM SPECTOSUM is, in my opinion, one of the most beautiful and satisfactory of our Lilies, whether for the house or open air. Its perfume is delicate, unlike the strong scent of *auratum*, and its graceful flowers are abundantly produced. It succeeds well in any light soil and is perfectly hardy, but I find that after a few years worms injure the bulbs, and it is best to take them up and replant them.

L. TIGRINUM.—What fine clumps of this one sees oftentimes in cottage gardens, and what a grand Lily it is! However, the old variety is eclipsed by splendens and *Fortunei*; the double Tiger is an effective flower, although lacking the grace of the single ones. As they come into flower somewhat late they are more useful.

L. BROWNII.—I cannot say that I have succeeded with this grand Lily, whose origin seems to be very doubtful, and a good deal of confusion has arisen as to its being the same as *japonicum*. It

seems rather difficult to determine, but Dr. Wallace says that after having grown the two side by side for a long time he is convinced they are distinct in every particular. In some gardens it seems to thrive luxuriantly, but neither in pots nor in the ground has it done well with me.

L. KRAMERI is another Lily I have failed with—I daresay through my own stupidity; but I have never happened to see it doing well where I have been. It is very beautiful, and succeeds, I believe, with Mr. Wilson and Mr. McIntosh; but that there is some difficulty about it I imagine from the fact that it is difficult to get English grown bulbs of it.

Such are some of the Lilies which I have tried, and while many of them have given me great pleasure, there are others which have been a vexation. Perhaps some of your readers can give me some clue as to the best way of cultivating those with which I have not succeeded.

DELTA.

ARCTOTIS ASPERA ARBORESCENS.

A PLANT of considerable beauty, but not often seen in gardens. As it is a native of South Africa, and therefore not hardy, cuttings must be made yearly, for which purpose July is the

Arctotis aspera arborescens.

best time for planting out the next season. It grows very fast, a single plant covering a space 4 feet in diameter before it is destroyed by frost. The flowers are large (between 3 inches and 4 inches in diameter); their colour a warm white, with dark centres. The stems are remarkably thick and furrowed; the leaves also are of some substance, with thick, fleshy midribs, so that the branches are heavy and apt to break down at the junction with the main stem. Both leaves and stem are of a pale grey-green colour. It is best suited for an isolated position on a sheltered, sunny bank, or in bold rockwork.

Cyclamen Coum and ibericum.—These are charming spring flowers, and well worth a place on the rockery where they can be sheltered from the sweeping east winds which usually prevail at this season, and which are very injurious to the flowers, as well as to the health of the plants. We find that they are much more floriferous and at home where they can be well sheltered than when exposed. A free, chalky soil, or one made up chiefly of broken pieces of lime and brick rubbish, suits them better than any other, and if allowed to sow their own seeds, hundreds of the tiny seedlings will be seen strewing the ground

the following year. If grown separately the seeds of each will come true, or nearly so, the variation being only within certain limits, but if grown side by side (and in this way the *Atkinsi* race was developed) they will hybridise freely, and the result will be numerous and varied coloured flowers, many of them far surpassing the types. The flowers of many of the varieties, especially the darker kinds, show considerable variation on the same plants at different periods. When first opened they may be bright purple, but towards the end they develop a pale, washy pink, very inferior to the first. We grow them in shade in a rough, gritty or lumpy soil, to which has been added about equal parts of stiff loam and leaf soil. The situation is well sheltered, and to this alone we attribute our early display of well-formed flowers. They are really handsome, the colours blend admirably with each other, and as we allow them to scatter their seeds and grow where they please, they form very effective groups. *Cyclamen repandum* and others will soon be flowering too, so that we expect a continuous display of these flowers for some time to come.—K.

Hardiness of *Ficus repens*.—I can confirm all "W. L." says about this (p. 163), and discovered it many years ago in a similar way to what he there describes. The plants clothed the inside of the wall of a plant stove, passed through several crevices, and also under the top ventilators, and so reached and largely clothed the outside, where they lived and thrived while the house remained. Since then I have often used it in the greenhouse and other cool houses, in which it has grown freely. This useful wall-cloth is less grown than it used to be, chiefly because its leaves are not popular, and its stem-root almost disqualifies it for table decoration. Still, it is used in some places for the latter purpose, and it forms a useful and a clean clothing for walls.—HORTON.

The Snowflake (*Lencojum vernum*), when grown in any quantity, is a charming flower for decorating the rockery or bulb border at the present season. It takes some time to get established—at least it has been so in our case—but when established it throws up its pretty, green-tipped flowers in the greatest profusion. Growing amongst the pure and large-flowered Snowdrops, such as *Galanthus Imperati* and *Elwesi*, it stands out prominently with its more robust habit and larger drooping bells. In the type the spots are green, but in the variety *carpathicum*, which until lately was comparatively scarce, the spots are rich golden yellow, and the scapes generally carry two flowers. This also occurs in robust plants of the common *vernum*, but is rather an exception. However that may be, they help wonderfully to attract attention to our spring gardens, and no grower should be without one or both of them. *L. hyemale* is also a pretty, though somewhat rare, bulb as yet, and as it is never likely to be grown successfully in the open, it is not of so much importance for outside work as the others. The flowers are white, produced long after the leaves have developed. *L. aestivum* and *pulchellum* are taller-growing, summer-flowering kinds, yielding large heads of many flowers, smaller than *vernum*, but with the green spots, and in the case of *aestivum* deliciously fragrant.—K.

SHORT NOTES.—FLOWER.

Daffodil Henry Irving. This is a variety of the sprays type with a broad yellow perianth and very large yellow trumpet. It appears to be a very early kind. We saw it recently in the gardens at Park Hill, Stratham, where it is greatly appreciated.—R. G.

Spring flowers.—During the past week we have had a mixture of fog, frost, and hot sunshine, and spring flowers do not seem at all happy under their influence—at least the few that have as yet ventured above ground. Snowdrops, Primroses, and Hepaticas look as if scalded, hardly a bloom fit to gather being left a result doubtless due to the action of bright gleams of sunshine on the frozen petals.—J. G. H.

Yuccas and Pampas Grass.—In our pleasure grounds there is a large and very fine bed of *Yucca gloriosa*, which at this season, when Nature seems, as it were, fast asleep, is very effective, the plants being furnished with deep green foliage close down to the ground. Fine, however, as the *Yuccas* are, an idea struck me that the appearance of the bed might be improved by intermixing them with *Pampas Grass*. The silver-like plumes of the *Pampas*

in autumn and winter would light up the scantier foliage of the Yuccas and add a charm to the bed.—R. GILBERT, *Burghley.*

FRUIT GARDEN.

W. COLEMAN.

RENOVATION OF LATE VINE BORDERS.

THE lifting and relaying of Vine roots, at one time looked upon as sacrilege, having been reduced to a system, there is hardly a garden of any note in which this important work is not more or less carried on from July to November, and, provided the operation is expeditiously performed, the full canopy of leaves the Vines are carrying not only favours their taking to the new soil before they fall, but enables them to carry fair crops of Grapes the following season. Early, mid-season, and autumn Vines, especially where they have the run of internal and external borders, come under this treatment, and the external borders of Lady Downes and Muscats may also be operated upon as soon as the Grapes are ripe, but few care to interfere with the interior until after they are cut. As these crops are allowed to hang till December or the early part of January, when the Vines are leafless and dormant, the cautious cultivator very wisely makes up his mind to wait until the sap is again on the move. It sometimes happens—I say this advisedly—that the great pressure of other work early in the spring prompts one to put off the operation of lifting until another season, and hope often against hope for better luck next time. He may blame himself for having given too much or too little water, or for the neglect of trifling details, but no matter how carefully these errors may be corrected, once the roots have gone wrong it rarely happens that anything short of lifting and relaying in sweet compost sets matters right. This, at least, is my experience, and knowing how quickly newly renovated Vines respond, and how pleasant it is to see them daily growing stronger, I cannot forbear advising all who are inclined to waver to take the bull by the horns, and I venture to say they will never regret having done so. Late Vines as a rule are still comparatively dormant, but they will soon be pushing, and so soon as the buds begin to swell the work of lifting may be taken in hand. Meantime, fresh clean drainage and new compost must be prepared ready for wheeling in, and, provided the latter can be allowed time to ferment, so much the better, as the condition of the newly-laid roots will then be precisely similar to that of pot Vines, which all agree should not be shaken out and repotted until after they have started. If new turf is to be cut for forming the border, it should be done during this exceptionally dry weather, for not only is it in the best possible condition for breaking up, but, provided it is thrown into a high ridge and protected from snow and rain, fermentation is sure to follow. Correctives generally consist of old lime rubble, road-scrappings, burnt refuse, and bones. The first should be broken down to the size of Walnuts, and used in the proportions of one to six. The second should be old, not green, and where the burnt refuse can be obtained direct from the fire, it will destroy wireworm, and be found a valuable aid in creating fermentation. Bones being rather expensive, this excellent stimulant is generally used in moderation, but quality being preferable to quantity, a well-made narrow border, to which a good lining of fermenting leaves can be added, always answers better than larger masses of compost without it. Assuming, then, that the internal border area is over 6 feet in width, and from 2 feet to 3 feet in depth, not more than 6 feet should be occupied

by fresh compost the first year, but the whole width should be effectually rubble-drained before a single sod is taken into the house. Upon this, the border, whatever width may have been decided upon, must be set out and covered with turf Grass-side downwards. Similar sods will be needed for building up the retaining-wall as the work of forming the border proceeds, and when high enough for relaying, all strong, fibreless roots may be laid in a diagonal direction, or cut back to a length shorter than the width of the border. When all are laid and covered, a moderate supply of water at a temperature of 90° will carry the soil home much better than treading, and assist fermentation. A light mulch of fresh, but short, stable manure will then be needful; otherwise, the surface will become dry, and the new roots will strike downwards, instead of upwards, in search of moisture. Now, this drawing them upwards being very important, and sweet, fermenting leaves plentiful, no harm will be done by placing a foot or so all over the surface, either on the top of, or in lieu of the mulch of manure. The vacant portion of the border area eventually to be filled up with new compost as fresh roots require it will then have to be dealt with. A long, narrow trench in ainery being inconvenient and the reverse of ornamental, it must either be planked over or filled up. I have said a lining of warm leaves will be found a great help to the roots—here, then, is the very place for it. Well worked stable manure will do; a mixture of manure and leaves will be better; but the best of all materials is a good body of Oak leaves, as the heat from these is steady; it lasts longer, and the gentle warmth and moisture rising from the surface will break and feed the buds where fleeting drenches through the syringe fail.

The American Blackberries are quite a failure with me. They cannot be induced to make any growth either with or without manure in the soil; I have tried them both ways. The only sort that makes any growth worth notice is the Parsley-leaved kind, but this cannot be compared with our native Bramble.—J. C. C.

Fig Pingo de Mal.—In the Southfields Nursery of Messrs. Veitch we lately had an opportunity of seeing a very fine collection of Figs growing for the purpose of comparison. The varieties there grown include Brown Turkey, White Marseilles, Negro Largo, Black Ischia, Bourjassotte Grise, &c. Among them the above-named variety, which was started at the same time and was undergoing the same treatment, was far ahead as regards earliness, being at least ten days earlier than any other. It is a very free bearer, with white flesh like the White Marseilles.

Cold storage for fruit is no longer an experiment, according to a committee appointed by the Pennsylvania Horticultural Society to examine into the subject. They visited structures costing from £60 to £2000. Dr. Funk's new building seems to be perfect in its working and simple in construction. It costs £1400. The walls are of stone, 2 feet thick; next to this on the inner side is an air space of 7 inches, and inside of that a charcoal lining of 4 inches. The storage room on the ground floor is 8 feet high and is divided into three apartments, all preserved at a uniform temperature of from 35° to 36° the year round. It has a storage capacity of 3000 barrels. The upper storey or ice chamber is 12 feet high, and holds 600 tons of ice. Flooding is omitted here, and the drip is provided for by means of galvanised gutters arranged to carry off the water without preventing the cold air from descending into the fruit room. The entire structure is 40 feet by 55 feet and 20 feet high. Barrels of cider placed in this house in the autumn are to day in perfect condition, the contents being as sweet as if just from the press. Duchesse Pears are keeping admirably, and to all appearance may be preserved until the next crop is placed in the market. A cheaper house, costing about £200, is recommended for marketmen and

small producers. It is 30 feet square and 25 feet high. The walls are of brick, 13 inches in thickness, and only extend as high as the first storey, some 9 feet. The ice apartment above is some 16 feet high, with air and charcoal chambers, as described above. The lower room is plastered only. This has a capacity of 900 barrels, and holds 300 tons of ice. Although there is no perceptible means of ventilating any of these fruit apartments, they are at all times dry and pleasant. As in ordinary ice houses, the contents must be well protected from the air by a thorough coat of sawdust and have ample ventilators at the roof. Success depends greatly on securing large masses of ice packed solid.

Cherries best on poorest soil.—Each succeeding year more fully convinces me that the greatest enemy to our cultivated varieties of the Cherry is a rich soil, not necessarily because a strong growth causes a speedy dissolution, but for the reason that disease is the inevitable consequence. It might not have been so in former times, but we have constantly new disorders in the vegetable world; so, while we do not know why a plethoric condition of the Cherry tree is the forerunner of some form of disease, it unfortunately follows, and the slow-growing, thoroughly-matured wood prospers only after its vigorous companions have passed away. What are known as the sweetest Cherries, mainly the Hearts and Bigarreus, are more susceptible of disease in some form than the Morellos, and as a safeguard they should be planted on rather thin, light soil, with little fertilising matter applied in after years. Mineral food is decidedly preferable, especially some form of potash, but avoid at all times rich stable manure. As stirring the soil is an incentive to growth, it is best to omit this as much as possible in the vicinity of Cherries; and as a tough sod retards growth, this should be encouraged close around the trees.—J. HOOPES, in *New York Tribune.*

Shading Muscats.—I have under my charge here two vineries used for growing Muscats, the foliage of which has for some years past got burnt. If there is one thing more than another to which I have an objection it is a scalded leaf in ainery. I have had the house re-glazed, and although there is some improvement, still a burnt leaf is often visible. Not liking the idea of being beaten, I, last season, shaded the lower lights of one house, but at the time I was somewhat in fear, if I shaded too thickly, I should lose the colour; but I am happy to say the bunches under the shade both swelled well and coloured perfectly. In the matter of shading I was somewhat perplexed as to what kind of shading to use. Summer cloud has been highly recommended, but I thought it too dark for my purpose; then the everlasting putting on and taking off scrim canvas could not be thought of. Mentioning the matter to my handy man, who, I am happy to say, never sees any difficulties, and telling him I wanted a nice light shade prepared, he answered instantly, "I can prepare you the very thing you want." This preparation is cheap, and once put on it will last all the summer, and is made as follows: To one gallon of skimmed milk add three-quarters of a pound of whiting, well mix it together, adding a quarter of a pint of linseed oil. This makes a very light, but efficient shade. There is some difficulty in cleaning the glass in the autumn, but that may be overcome by taking an ordinary square of glass and scraping off the mixture.—L. G.

Melons, old and new.—No one can doubt that we are overdone with new kinds of Melons of very doubtful merit, which are frequently recommended, to the injury of old and better flavoured sorts. After having met with many disappointments in the so-called new kinds, I have made up my mind to ignore their existence altogether if I can only meet with the sorts that were extensively grown thirty years ago. These were the Beechwood (scarlet flesh) and the Egyptian (green flesh). If I could meet with these now I should not grow any other, and I am sure that all concerned would be benefited. I should not only get sorts that have sufficient strength of constitution to retain their foliage in a green, healthy condition until the fruits are ripe, but I should have size and flavour equal to that of the most popular sorts now grown. The greatest evil attending the growth of the newer sorts is that they

have an awkward way of losing most of their largest leaves a short time before the fruit gets ripe, and as a consequence the flavour is inferior. It appears to me that the new sorts are more tender than the old, and the only satisfactory way of growing them is to give them a richer soil than is usually provided for Melons. I find they retain their leaves better when one-fourth part of manure is added to the loam, but this is not wholly satisfactory.—J. C. C.

PROTECTING THE BLOSSOMS OF FRUIT TREES.

FRUIT trees of all kinds are looking very promising, the blossom buds being very numerous and strong. The end of last summer was dry and warm, and the wood ripened well. We have young shoots of Apricots from 15 inches to 18 inches long well set with blossom buds the entire length, which is a sure sign the ripening period was a favourable one. The blossoming period this year is very late, and this is generally considered a point in favour of safety. Taking the average of seasons, according to my notes, here for the last eighteen years, the Apricot blossoms begin to expand about the 12th or 13th of March, but this year they will be later than the average. There are generally local conditions and circumstances which should be taken into consideration in selecting and apportioning the covering for fruit tree blossoms. The mere fact of a wall being well situated as regards shelter from cold winds will make several degrees' difference in the temperature. Again, a dry wall in a sound condition as regards construction and coping is much warmer than if the damp is permitted to penetrate. All garden walls, I think, should be hollow. The wall of a building, sheltered by protecting eaves from which the water is conveyed by sound gutters, is better adapted for choice fruits than a garden wall, even if well coped and dry. Something depends, too, as regards the amount of shelter to be given upon the way the trees are pruned. If there are long spurs projecting from the wall, the blossoms will be exposed to more danger than if the practice of laying in plenty of young wood has been followed for some time.

We cannot treat the Apricot like the Peach, as it would involve too much knife work, but the spurs should be kept close at home, and as much young wood should be laid in as possible without crowding, and the latter is most important if the wood is to ripen and the buds be fertile. It may be thought this has not much to do with the protection of fruit-tree blossoms, but it has a good deal to do with it if the covering is to be just equal to the object desired—neither too heavy or too light. Some years ago we had a number of Britain's wall nets, but the wind from the German Ocean, which at times rushes across the fens with considerable force, there being nothing to check its career, soon blew it into rags, and now we use, as a rule, no other coverings but Yew branches and fishing nets, which are cheaper, involve less trouble, and are quite equal in results to anything we have tried previously. The Yew sprays are fresh cut from the bushes about a foot long; the thick ends are pushed in under the branches of the tree, and the feathery spray hangs down over the blossoms, not only affording shelter, but keeping them dry. They are not placed in so thickly as to darken unduly, as I am convinced too much covering is hurtful to the trees both now and hereafter. When a sufficient number of branches are placed on the trees a fishing net, as wide as the wall is high or nearly so, is drawn over and secured; if there was no net, the wind would scatter the branches all over the garden. There is also in connection with this kind of covering another advantage, as by the time the fruits are set and the foliage requires more light and air the leaves are falling from the Yew branches, so that day by day there is an increase of exposure, and where this increase is too tardy or too long delayed it is a very easy matter to get in behind the nets and remove, as occasion requires, a few of the sprays to let in more light and air as the trees need it. When

heavy coverings are used their daily removal when the weather is fine is a necessity, and the soil about the trees often gets trodden into a quagmire, and scarcely recovers its tone during the season. E. HORDAY.

Market Apples of the future.—These should be above middle size, good in colour, and free bearers. They should either be early autumn varieties or late spring ones. To cultivate Apples for a mid-season supply is a delusion, as at that time the Americans beat us—not as regards quality, but in good looks and good prices. For an autumn supply of dessert Apples I should recommend King of the Pippins, Cox's Pomona, and Irish Peach. For kitchen use, Schoolmaster, Grenadier, and Lord Suffield. For a late spring supply of dessert Apples, I would plant May Queen, Sturmer Pippin, and Margil. For a spring supply of kitchen Apples, I do not think anything can equal the Wellington, Barnack Beauty, and Impératrice Elizabeth. Be it clearly understood, however, that I should not recommend these twelve exclusively for a nobleman's garden, because we have some equally good, if not better, as, for instance, Wycombe Pippin, Kilston Pippin, and Cox's Orange Pippin, but being shy bearers they are unprofitable to the Apple grower.—R. GILBERT, *Borghley*.

SEASONABLE WORK AMONG FRUITS.

STRAWBERRIES.

THE weather throughout the past month having been exceptionally fine, early plants have made rapid progress, and the first batches will be fit for removal to the hottest houses, where they will remain until the fruit is ripe. When this move forward is made the plants should be well syringed to free them from spider, and regularly fed with liquid of a generous nature, but not too strong. Many growers use saucers, but a man who waters judiciously does not require them, and certainly the best flavoured fruit is obtained from plants whose crock roots are never choked by stagnant liquid. If free kinds have set abundantly, the fruit should be well thinned, a dozen good average-sized Strawberries being quite sufficient for the crop. The best time, however, to thin is before the flowers open, as the removal of all weak side buds throws strength into those left, and, provided other conditions are right, there exists but little danger of their setting. Some forcers allow the fruit to hang over the sides of the pots to ripen, others tie every truss to small sticks, but small forked pieces a few inches in length stuck into the balls answer as well as anything. Where large batches of plants are started together the first selection for the fruiting house favours a general re-arrangement, and, as a matter of no small import, a complete change of position. The most forward can then be conveniently placed for fertilisation, whilst those taken in to fill up the rear can be regularly syringed until they come into flower.

Succession.—Large or small batches, according to the stock, of the mid-season varieties should be taken into a moist temperate pit or house about once a fortnight, well watered and syringed, and fumigated occasionally to secure immunity from fly when they come into flower. Pot Strawberries have many enemies which lurk through the winter and spring into new life when introduced to the forcing pits. Spider, fly, and mildew are sometimes troublesome. The first and last, in hot, dry gardens, often cling to the old leaves throughout the winter, and start up in full vigour just when they are least wanted. Sulphur in some form is the best remedy, but prevention being better than cure, the plants, when these pests prevail, should be immersed in strong soap water, to which a few handfuls of sulphur has been added, as they are taken from their winter quarters.

Late plants intended for fruiting in cold pits and keeping up a supply through May should have full exposure through the early part of bright, fine days. If plunged to the rims in leaves they will not require daily watering, but on no account

must they be allowed to become dry; therefore during the time the lights are off they should be carefully supplied and closed with sun heat to help the crowns forward. Plants of some kinds, notably President, in cold pits are very subject to mildew, and as this spreads rapidly, dry sulphur from the outset should be freely worked amongst them.

From the forcing houses to stock plants on the open quarters is but a step, and as future success entirely depends upon an early start with runners, these should now be looked to. Some depend upon early forced plants for their first runners, but independently of the presence of spider, their constitutions are weakened by hard forcing, and the best they can give lack vigour. To maiden plants of the past year then we must look, and as these may have been lifted by frost and affected by drought, they should be well firmed and mulched, and liberally supplied with water. If we watch the shrewd market gardener we see him forcing early growth with an abundance of stimulating food, and as this is just what the early Strawberry forcer wants, he cannot do better than follow his example. Plants from which runners are to be taken should not be allowed to produce flowers, as the production of good fruit and early stock are incompatible. Therefore the better to husband their vigour and prevent degeneration every scape should be removed as soon as it is visible.

PEACHES.

To the experienced cultivator the usual routine of disbudding, heeling down, and thinning of fruit will fall as naturally as night follows day. To the inexperienced some of these operations may appear extremely difficult and mistakes may be made, but provided they proceed with caution and allow this work to extend over two or three weeks, they will find a place for every shoot, which must have plenty of room for the full development of its foliage. The most common mistake in disbudding and tying down is that of leaving too much wood, but as this happens to fall on the right side it can always be remedied by the subsequent removal of as many intermediate growths as will give a space of 6 inches to 9 inches to each shoot. A good shoot close to the base and another at the point are imperative, otherwise the finest tree in a year or two will be little better than a skeleton, and without an even spread of foliage the crop the first season will not properly swell to maturity.

Thinning the fruit, in like manner, is a piecemeal operation, and must be governed by the age and strength of the tree. Hale and healthy trees that have filled their allotted space set very freely and mature fine highly coloured fruit; but they must not be overloaded, otherwise they will balance the account by refusing to lay on the last ounce of pulp, and by ripening up the crop prematurely. When a tree is overloaded it allows the fruit to drop, or part, when touched by the hand; when fairly balanced, full size is attained and the Peaches will hang for some days after they are dead ripe. Allowing them to remain until they are in this condition is not, however, good policy, as piquancy of flavour at this stage gives place to flatness, but this staying power is the best of all tests of judicious thinning. A good Peach tree will finish a large fruit for every square foot of trellis covered with foliage; possibly under high pressure it may ripen a few more; but the weight of pulp in the aggregate will not be equal to that of the smaller number, simply because a greater number of stones and kernels have to be formed and perfected. We sometimes hear of Peach trees carrying double this number of fruit; but, in the first place, this overcropping is suicidal; in the second, absurd reports are received by many as facts, and lead to unpleasantness between employers and their gardeners.

Heeling down—When the trees have been well disbudded, and the fruit reduced to within 40 per cent. of the crop, the young shoots should be neatly tied in, almost close to the wood from which they have started. This process will give

them a set in the right direction, and as Peaches make rapid progress when a little freedom is allowed, they may then be left alone until the shoots are 6 inches to 9 inches in length. The strongest near the extremities, also leaders, must then be tied down, but weak growths near the base will best hold their own by growing upwards for a week or two longer. As tying is proceeded with, an eye should always be kept on strong growths, which, unless they are leaders, must from time to time be pinched to strengthen weak parts and maintain the even balance of the trees.

Water in plenty and good syringing must not be overlooked, and the fumigator may be needed occasionally, but unless those pests, pot Strawberries, have been in the house, good culture should now keep the trees free from aphids. The water given to the roots should be warm, and that used for syringing free from lime, otherwise the woolly coats of the Peaches will soon be disfigured. One of our best plant growers assures us that cold water answers quite as well as warm. I am not prepared to contradict him, but I must confess a strong leaning to the tepid bath not only in forcing houses, but wherever rapid progress is of importance.

Mid-season houses. The trees in these have had an exceptionally good time for setting their fruit. We generally run over them with the brush, but this season fine, sunny days have brought the hive bees to our aid, and every flower appears safe. So much for our fickle seasons; last year at this time we were half buried in snow, and were obliged to sweep the roof of the same house to let in daylight. The fruit nevertheless set well, although the temperature sometimes nearly touched 32°. Many people dread allowing their house Peaches to fall below 45° when in flower, but this fact proves an assertion I have often made, that any temperature short of actual freezing is not unfavourable to the setting of the fruit, always provided the trees and atmosphere of the house are kept proportionately dry. I do not, of course, advocate this close sailing, but the remark just now comes *apropos*, as late houses this season are unusually forward, and those who have not yet invested in hot water, whilst quaking under unusually sharp frosts—12° on the 1st inst.—may cull a grain of comfort from the information. I would not, however, have them go too far, as March frosts equally severe may follow cold, wet days, when the result will be less satisfactory.

Where fire-heat can be applied in cases of emergency, these late trees will now derive great benefit from daily syringing, but, having full command of the situation, early closing with strong sun-heat will not be necessary. Water, too, through the hose must be freely administered not only to internal, but to external borders also. Last year, after heavy falls of rain and snow, I neglected the hosing of an external border before it was mulched in March. The flowers set well, but all the fruit did not swell away kindly, and although I had a good crop, the check was afterwards traced to want of water. This season we have not had a day's rain since Christmas; consequently I am now giving a second supply of water. This garden lies low and damp on a cold bed of limestone marl. How external borders in high and dry gardens may have been affected I leave their owners or managers to inquire. If water is plentiful, a few inches will do them no harm, as drought at this critical period is quite as fatal as frost. If the trees are swelling a profusion of flower-buds, those on the upper sides of the shoots can be greatly strengthened by the removal of the lower half. This operation can be quickly and effectually performed by drawing the finger down the undersides of the flowering wood. As late Peaches always set freely, assisted fertilisation is of little consequence; still when the cultivator wishes to make success certain, an occasional run over with the brush will set his mind at rest. Smoking, on the other hand, is very important, and should be performed two or three times during the ten days preceding the opening of the first flower.

CUCUMBERS.

As some of the oldest winter plants will not only be growing stale, but their room in many places will be required for Melons, spring-sown plants should be worked on as rapidly as may be consistent with the maintenance of a sound constitution. Pot culture is generally considered the nearest approach to express speed, as an abundance of bottom-heat can be given to the roots, and the stimulating gases constantly rising from the decaying leaves exactly suit the foliage. Heat and moisture being the main factors, a range of 65° to 70° by night and 75° to 80° through the day will ensure rapid growth of vine and fruit, especially if this bright sunny weather favours running up to 90° after closing with moisture. Shading, if possible, should not be commenced, as plants so treated give a great deal of extra trouble throughout the season, and, being rendered extremely tender through want of light, they are always susceptible to the ravages of insects and mildew. As these plants are expected to continue in bearing throughout the summer, close or crowded planting should be carefully avoided, and, the better to secure a good foundation, they should be manipulated and tied in at least twice a week. Light cropping at all times, but especially when the plants are young, cannot be too rigidly enforced, and in order to husband their strength every fruit should be cut before it attains its full size. A Cucumber 12 inches to 14 inches in length is a very convenient size both for private and market use. For special purposes they may be grown to a larger size; but for quality and profit, fresh, quickly-grown fruit, with the flower attached, cannot be surpassed. Where winter plants are grown in several small compartments, the month of March is a good time to commence cutting over those which have been longest in bearing. By cutting over, it must be understood that all the fruit, large and small, long straggling vines and a few of the worst leaves must be removed. Cleansing the house and dressing the plants with insecticides will then follow; but the work will not be complete until exhausted mulching and sour compost have been replaced with fresh, warm, turfy loam. A bottom heat of 80° to 85°, from fire and fermenting material combined, will immediately restore root-action, and fresh fruitful growths in due course will refurbish the trellis. Once a fresh start is secured, ordinary treatment will keep these renovated plants not only in bearing, but extremely fruitful for some months to come.

Cucumbers in frames.—When the beds have lost their fierce heat and the young plants are ready for turning out, the hills or ridges of light, rich, turfy loam should be formed on a good base of large sods turned Grass-side downwards. These sods act beneficially in two ways: in the first instance they keep down strong heat and injurious steam; in the second they keep the compost sweet, and prevent the strong roots from striking into the bed of decaying manure when the heat is declining. Rank, unmanageable growth, of course, follows, but the Vines are unfruitful, and a spell of cold, sunless weather or too much water not unfrequently bring on an attack of canker. A gross habit of growth in frame Cucumbers or Melons being strongly objectionable, too much attention cannot be devoted to these intercepting sods, and mixing animal manure with the compost should never be practised. When the hills are thoroughly warm and the heat stands at 80° they will be in suitable condition for the reception of the plants, but on no account should they be turned out until the bottom-heat is steady. If the roots have commenced coiling round the balls, they should be very carefully loosened with a finely pointed stick before the warm compost is placed around them. This matter, trifling in itself, is very important, as I have seen failure follow planting where this detail has been neglected. A little warm water will settle the soil about the roots, but the balls being thoroughly moist at the time of turning out, this element for a few days must be given

sparingly. Slight shade if the plants flag may be necessary, and the invisible enemy, rank steam, must be allowed to escape by giving a chink of air very early. Linings at this early and uncertain season should be placed round the frame at the outset, and well-worked manure and leaves should always be on hand for renovating when necessary. The next and last item for the present is covering, for without this checks and chills will heavily handicap the best frame cultivator; nay, more, with only a thin sheet of glass above the tender foliage heat will escape much faster than the best fermenting materials can possibly generate it. Bass mats hitherto have been extensively used, and there exists a feeling of comfort and security from outward pressure when the lights are snugly covered with a double thickness of dry mats. Against wet, unfortunately, they are not proof, but then there are other materials which may be used for throwing off rain and snow if gardeners who have not been half spoiled by hot-water pipes would take the trouble to provide them. First of all we have the substantial reed or straw hurdles, wooden shutters, corrugated sheets, the market gardener's rough-and-ready, but none the less effectual, covering of long litter, and, last of all, oiled canvas sheets, which can be obtained of any length and width with short cords attached for securing them in windy weather. These I can strongly recommend, as they are clean, neat, and cheaper than mats in the long run, but being naturally cold a dry mat should be placed next the glass to form a warm non-conducting medium in bad weather.

W. C.

GARDEN FLORA.

PLATE 587.

THE ALGARVE SUNROSE.

(HELIANTHEMUM ALGARVENSE.*)

WITHIN the last two years we have given in THE GARDEN no fewer than four coloured plates of Sun and Rock Roses, but they are so numerous, so beautiful, and such important garden plants, that they well deserve to be better known in order to bring them into more general cultivation. The Sun Roses we have previously figured are *Cistus florentinus*, *C. formosus*, otherwise known as *Helianthemum formosum*, and *C. ladaniferus* var. *maculatus*. These are all delightful shrubs, yet are not to be found in one out of a hundred gardens, even in the southern counties, where their hardiness does not cause much anxiety. Fifty years ago both *Cistus* and *Helianthemum* were extremely popular, and the kinds grown could have been counted by the hundred, if the forms of the common *Helianthemum vulgare* were included. So important were they considered, that the botanist Sweet published a book sixty years ago, which was entirely devoted to illustrations and descriptions of Rock or Sun Roses. The book is called "*Cistinea*,"† and may be bought second-hand, though somewhat rare. There is, and always has been, great confusion in gardens as regards the nomenclature of *Cistus* and *Helianthemum*, and one rarely sees a species under the same name in two collections—the *Cistus* and *Helianthemum* being so much alike in flower, and often in habit, that the confusion is pardonable, especially when the confusion is commenced in the case of several species in such authoritative works as the *Botanical Magazine*. For example, the plant we herewith figure as *Helianthemum algarvense* appeared in the *Botanical Magazine* (plate 627) as *Cistus algarvensis*, and under this name it is grown and

* Drawn by Miss Lowe, Woodcote, Wimbledon, and printed for THE GARDEN by G. SEEVERS.

† *Cistinea*: the Natural Order of *Cistus* or Rock Roses. Illustrated by coloured figures and descriptions of all the distinct species and most prominent varieties that could be at present procured in the gardens of Great Britain. By R. Sweet. 1830.

HELIMPHYS ALBA (L.) DC.

sold in nurseries generally. It is a true *Helianthemum*, but it is known by several aliases. *H. algarvense* is the name followed by some botanists; others call it *H. ocymoides*, or the Basil-leaved Rock Rose. It matters little which is correct, so long as we have such a beautiful plant in plenty, and up till now it is one of the few of that long list of sorts grown, as we have said, fifty or sixty years ago.

Accompanying the plate of *Helianthemum formosum* given in THE GARDEN (Vol. XXVI, p. 420), an admirable descriptive account appears of the chief species of *Helianthemum*, written by Mr. G. Nicholson, of Kew, who also gave a similar account of the species of *Cistus* in Vol. XXVII., p. 570, accompanying the plate of *Cistus florentinus*. In each account Mr. Nicholson reviews the genus, describes the species, and quotes a list of their chief synonyms. There is, therefore, no need for us to go into the subject here, as anyone desirous of getting information can refer to those volumes.

The Algarve Rock Rose is one of those beautiful shrubs growing wild in the south-western parts of Europe, chiefly in Portugal, where it is most plentiful in the Algarves; hence the name, Algarve Rock Rose. It grows from a foot to a yard in height, and varies a good deal in size of foliage and the intensity of the blotches on the petals. The flowers remind one strongly of those of that pretty annual, *Calliopsis bicolor*, but while this is a late summer plant, the Rock Rose flowers in early summer. As in the case of other Portuguese species, it is not an absolutely hardy plant, and in most places requires a little protection during winter. But such a charming plant is worth any attention. It should always be planted high and dry, never on the flat, and in light soil well drained, as these conditions always favour its hardiness. It need hardly be said that every Sun Rose and Rock Rose should be planted where they can get the full sun. They are children of the sun and cannot exist without it; it is their life. Miss Jekyll is very fortunate with Sun and Rock Roses at Munstead. She plants them on a high and dry bank, scattered here and there with big boulders, and there the plants spread and grow in their own way. And this particular bank is a glorious sight in flower-time, for though each flower does not last more than a day, the crowds that every bush produces in quick succession make the flowering season extend a long time. Sun and Rock Roses should always be planted in open and warm places, and always in groups by themselves so that they may be easily protected during winter should occasion require. Some recommend planting them on the "margin of shrubberies," a common phrase, but very indefinite, and of all places it is the worst for these shrubs for several reasons. They are apt to become overrun by stronger growing shrubs, or are shaded by them, and, worse than all, strong-growing shrubs if near soon impoverish the soil of the best-made Sun Rose border. A raised knoll—rocky, if you like—is the place for *Cistus* and *Helianthemum*, and with the variety of sizes, heights, and habits to be found even among those that are still in cultivation, one can make most picturesque groups, and so arrange them that their glowing yellows, pure whites, rich crimsons, and pinks may harmonise in a beautiful way. One often sees Rock Roses planted on a heap of stones or brick rubbish, which is a mistake, for although they like to thrust their roots beneath stones to get moisture in summer, they want good soil, as other shrubs do. We are now planting a group of *Cistus* and Rock Roses in a Surrey garden, and we have so arranged them that the tender *Cistus* make the main group by themselves and can be readily

protected in winter, while outlying masses or groups consist of *Helianthemum*, about whose hardiness we have no doubt. W. G.

STOVE AND GREENHOUSE.

T. BAINES.

EARLY FLOWERING PELARGONIUMS.

THE large-flowered varieties of *Pelargonium* being as a rule banished from greenhouses in private gardens is the reverse of a gain. It would be difficult to point to any section of plants that afford such a wealth of rich and varied colours as we meet with in the almost endless varieties that have sprung from the pretty, but insignificant Cape species, to which the present race of these plants owes its parentage. More recently the zonals were taken in hand, and with them also much was done in raising varieties with larger flowers than the older sorts possessed, and amongst the varieties obtained by the English, as well as the Continental raisers there are many with colours altogether new and distinct from the older race of zonals. The new varieties, in common with the old sorts, are proverbial for their continuous habit of blooming, continuing to produce flowers more or less so long as the plants are kept in a growing temperature, even during winter. This natural disposition in the zonals to keep on giving a succession of flowers, combined with the little skill required in their cultivation, has had much to do with the extent to which in recent times they have been grown, an extent to which, whilst admitting all that can be claimed for them, has been in excess of their merits, as at best there is an absence of refinement in the colours of their flowers and a sameness in their general appearance that places them in an inferior position to the large-flowered division, which they have now in a great measure superseded. For a long time there was one feature common to all the large-flowered varieties that made their appearance, that is they were late spring or summer flowerers, their habit of growth being such that if subjected to the amount of warmth which the zonals would bear they made an undue amount of top growth, the shoots and leaves becoming weak and drawn, the plants showing little disposition to bloom. But more recently a distinct section of large-flowered varieties have been raised that will stand as much heat as the zonals, and that will come into flower eight or ten weeks earlier than the generality of the old sorts. The following are the best of these early kinds, with a brief description of the character of their flowers:—

- VIRGINALE.—Pure white ground, with a faint dash of crimson on the base of the top petals. This is the earliest bloomer of the varieties under notice, beginning to flower in February.
- SMITH'S SEEDLING.—French white, with carmine spot on each petal.
- WILLIAM SMITH.—Flesh ground-colour, with small chocolate spots.
- MRS. W. DAVIS.—Pale pink, with maroon spot on top petals, crimson spot on lower petals.
- CHAMELEON.—Deep scarlet, with small dark spot on each petal.
- ETNA.—Intense, vivid scarlet, centre violet, maroon feather on top petals.
- IMPROVEMENT.—Crimson, dark-feathered spot on the petals. This variety produces an immense head of bloom.
- MRS. LEWIS LLOYD.—Deep velvety crimson, violet centre, deep feathery markings on top petals.
- CHIMENE.—Bright crimson-red, with deep-coloured blotch on each petal.
- MONS. ROTILLARD.—Deep crimson, violet centre, petals edged with white, dark chocolate blotch.
- KINGSTON BEAUTY.—Pure white ground, purple spot on top petals.
- EMELIE EVERARD.—Vivid scarlet.
- DEFIANCE.—Scarlet, violet centre.
- SCARLET GEM.—The brightest scarlet.

The first named three or four sorts are the

earliest bloomers, *virginale* being, as already said, the earliest of all; the flowers of this variety are mostly sold in a cut state. Plants of the other kinds generally appear in the market about the beginning of March. All the varieties mentioned, except one or two that have come from the Continent, have been raised by the market growers, and are the pick from untold numbers of seedlings, as no variety is of the slightest use to them unless the colours are pure and delicate, or bright and vivid, combined with a profuse flowering habit and sturdy compact growth in the plants, such as will enable them to bear being kept considerably warmer all through the winter than the ordinary large-flowered sorts. It is scarcely necessary to say that when pushed on into bloom thus early the plants must be grown in light, well-constructed houses, and stood well up to the glass, enough heat being kept up to allow of more air being given than is generally considered sufficient for *Pelargoniums* in the winter season. This extra amount of air suits them when, as already said, it is accompanied by a corresponding amount of warmth, as, in common with all the *Pelargonium* family, they like a somewhat drier atmosphere than is necessary for most plants. For the various purposes for which cut flowers are now required, as well as where the plants are wanted for decorative use, these early blooming, large-flowered varieties of *Pelargonium* distance the zonals, except, perhaps, in the estimation of those who look upon a bed or a houseful of scarlet or crimson as perfection in floral colour.

USEFUL GREENHOUSE PLANTS.

AMARYLLISES.—Some growers re-pot their *Amaryllis* bulbs in autumn; others, late in spring. We re-pot ours in the first or second week in January. One large grower with whom I am acquainted thinks it best not to re-pot them oftener than once in two years; and in favour of all these systems of treatment there may be something to say. A good deal depends upon subsequent management, and also as to the time when they are expected to be in flower. Several growers, for instance, have told me that they succeeded best when they did not re-pot their bulbs, the reason alleged being that, after potting, the roots from the base decay, and that will happen if they get too much water before they have well started into growth; but if not watered for a month or six weeks after being re-potted, they will be all right. We grow nearly a thousand bulbs of all sizes, and although all of them were potted by the 10th of January, not one of them was watered until the middle of February; by that time they had grown considerably, and numbers of them were pushing up flower-spikes. We also maintain a moderately dry atmosphere at first; otherwise some of the bulbs decay at the crown. When in full growth, all danger of decay both above and below ground is over, and being plunged in bottom heat but little water is required. I always raise seedlings of these, and also of other flowers which we cultivate, and in a very few years we have had a small measure of success. The seedlings raised last August are now growing freely, three plants being in a 4-inch or 5-inch pot. In these they will produce good, large bulbs before the end of the season. Plants a year older raised from seeds are now growing singly in a 4-inch or 5-inch pot, and a very small proportion of these will flower this season. *Amaryllises* are easily hybridised; the anthers are removed with the finger and thumb before the pollen is shed—that is, when the flowers are partly open. In thirty-six hours subsequently the foreign pollen may be applied to the stigma. The seed-pod will take about three months to ripen.

CINERARIAS.—These have passed through the winter extremely well, although it was necessary to use a good deal of artificial heat, which *Cinerarias* dislike. It is interesting work tying and training the plants that are to flower in the shape

of large specimens in April. The object of tying out the flowering growths is to secure a regular head of bloom, which will show the individual blossoms off to the best advantage. A very little practice will enable the cultivator so to do this work that the plants when in flower will not exhibit in any way the ill effects which usually arise from bad training. Plants to flower in April should be staked at once, or they will not have time to grow into natural form by the time the head of bloom is fully developed. We had a serious attack of mildew this year, but its advance was checked by prompt application of flowers of sulphur. Thrips and greenfly should be destroyed by means of tobacco smoke; it is best to fumigate every month as a preventive. The plants will be dwarfer in habit and the flowers more brilliant in colour if placed close to the roof-glass. A plentiful flow of fresh air should pass through the ventilators, without causing a draught, which would certainly be injurious.

CALCEOLARIAS.—These flower later than Cinerarias, but the treatment which they require is much the same; if anything the leaves are more easily injured by greenfly than those of Cinerarias. When once this troublesome pest gains a foothold the rapidity with which it spreads is marvellous. Calceolarias may be had in excellent bloom during May; therefore any plants not yet in their flowering pots should be repotted at once. They grow rapidly during March and April, and if handsome specimens are expected they must have daily attention. They require considerable supplies of water when the pots are well filled with roots, but for a few weeks after repotting attention is necessary in order to prevent the fresh potting material from being over-charged with water before the roots have thoroughly permeated it. Some growers syringe the leaves of their Calceolarias, but I have never done so, believing that they do better without it. It is necessary to move each plant occasionally in order to examine it underneath, as dead or decaying leaves must be removed. After a week or so of dull, cold weather, the sun may shine out brightly, and the sudden change will check the plants, unless some thin shading is thrown over the glass during the hottest part of the day.

WINTER-FLOWERING CARNATIONS.—Mr. Gilbert's experience is that of many others. Only a few varieties flower well at mid-winter, but nearly all that are termed perpetual flowering will do remarkably well after the middle of February, and they are valuable during March, April, and May. Mr. Gilbert ought not to condemn the varieties which he names because they refuse to be coaxed into flowering at Christmas. His culture was also faulty in some respects. The plants ought to have been placed outside long before August, and close to a south wall is perhaps not the best place for them. Their propagation and cultural details may be summed up in a few words. The earliest cuttings should be put in about the middle of January, and the latest at the end of March. Every cutting will form roots if the small side growths are merely slipped off and inserted in fine sandy soil, using 4-inch or 5-inch pots. Plunge the pots in bottom-heat in a forcing house. We propagate two varieties in one pot, as we do not require a large number of plants. When the pots are plunged, lay squares of glass resting upon the labels over them. This is sufficient to retain moisture about them, and none of them will damp off, as they might do if kept too close under a handlight. When they are rooted pot off at once, placing the plants on a shelf near the glass. They are gradually inured to a cooler house, and may be placed in frames about the end of April. Draw the lights quite off in fine weather, and about the end of June place them out of doors in an open position. The Carnation likes plenty of air, and if stifled under a south wall, red spider and other pests may be troublesome. The earliest propagated plants will grow into large specimens, requiring 7-inch and 8-inch pots to flower in, and those varieties that will not succeed at mid-winter will do so between February and midsummer.

Some of them will also produce flowers in October and November. J. DOUGLAS.

SPRING TREATMENT OF FUCHSIAS.

Few plants are more generally cultivated than Fuchsias. They find a place in every large or small greenhouse or conservatory, and as window plants they are more commonly grown than anything else. The best treatment Fuchsias can have in winter is to keep them perfectly dry at the roots, and in a temperature low enough not to excite growth. They may be placed under these conditions from November until March, but about this time they should be taken in hand, and their culture commenced for another season's display. Many of the shoots formed last year will be straggling, and if these were left on they would not improve the appearance of the plant, and the whole of the side twigs and shoots should be cut well into the old wood, as the short spur system of pruning suits them admirably. There is little danger of cutting them too much. When pruned at this season they need present little or nothing but a bare main stem covered with side spurs, and may then be placed in a moist atmosphere where the temperature ranges from 60° to 70°, and if well watered at the root from the first and frequently syringed they will break into growth very freely. Repot when growth begins, the best time being when the young shoots are from 2 inches to 3 inches in length. In potting, turn the plants out of the pots they occupied last year, and shake all the old loose soil from the roots. This will enable the operator to pot the plants in smaller pots than those they have just been taken out of, and this is the proper thing to do, as by potting in smaller sizes now, they can be placed in larger pots when they have advanced in growth, and this is always beneficial. After potting the first time, the plants may be returned to the quarters in which they were started, taking care to syringe freely until the roots have taken possession of the new soil; and if compact, bushy plants are desired, the young shoots should be pinched at the points from the time they are 3 inches or 4 inches long. They delight in a rich mixture at the root, and this may consist of two parts loam, one of manure, and one of sand.

PILLAR FUCHSIAS, which may be growing in beds and borders, should also be pruned in well at this season. A rich surface-dressing should be applied if the soil is poor, and abundance of water should be given at the roots. Syringing is also advantageous, but manure-water need not be given them until they are considerably advanced in growth. Where the plants were infested with insects last autumn syringe them frequently with some insecticide, as many of the insects or their progeny are sure to be lurking about the bark now. CAMERIAN.

An American note on Amaryllids.—I am a subscriber to a number of German, American, French, and English gardening periodicals, but none is so highly welcomed and read with such delight by me as THE GARDEN. Every flower and plant-lover finds in its pages something, indeed very much, of great interest. The coloured plates, too, are excellent. I cannot do without THE GARDEN. I am an enthusiastic lover of Amaryllids, and I think there are many more who like them among your readers. Can you give us now and then a few coloured plates of fine English hybrids? Many have no idea of such celebrated kinds as Empress of India, Mrs. Burbidge, Eucharis, Ornata, Masterpiece, &c. Years have passed since the last plate of Amaryllis (Mrs. Garfield) appeared. I wish an English botanist could give us a new and revised edition of Dean Herbert's "Amaryllidaceae," or, what is still better, an entirely new and good book on this beautiful class of plants. There is so much confusion now among plant-lovers about Crinum, Pancratium, Hymenocallis, &c., that a work of this kind is a great desideratum. The books on bulbs written by Raul, Fish, and Ruempler are of very little value to Amaryllis lovers. No language can boast of such a work on Orchids as "The Orchid Album;" why cannot we get an Amaryllis album? Can any lover of the family answer in THE GARDEN the following questions: Is there in existence a book with coloured plates on Amaryllids? Can you give in THE GARDEN correct lists of Crinum, Pancratium,

Hymenocallis, or can good monographs of these genera be obtained? Do Hippeastrum and Crinum cross with each other? I have a few Amaryllids (A. Olga and A. grandis) which have leaves like Crinum, but the flowers are more Hippeastrum-like. Although it is said in some catalogues that these kinds were raised by crossing Crinum with Hippeastrum, I do not believe it, as both genera are so entirely different. —H. NEUBLING, *Ficistatt, Lawrence Co., Mo., U.S.A.*

PERSIAN CYCLAMEN CULTURE.

To see a batch of Persian Cyclamens in their true beauty is a sight not to be soon forgotten. When well grown it is difficult to find a more useful plant than this for greenhouse, room, and window decoration. They are also useful for supplying cut flowers for vases or bouquets, for, when placed in water, they retain their beauty for a long time. There are various species of *C. persicum* producing flowers varying from deep red to a pure white.

Cyclamens should be raised from seeds, which, if carefully attended to as regards potting, will flower within a year from the time of sowing, but when neglected, two or three years are required before they flower. The seed should be sown in a well-drained pan, filled to within half an inch of the rim with good loam, leaf-mould, and plenty of sand. Give the surface a gentle press, so as to level it; then sow the seed evenly, and cover with fine soil, water gently, and place in a temperature of 65° to 70°; keep the soil moist, and as soon as the seedlings appear, raise the pan as near the glass as possible, and shade from the sun during the middle of the day. When the plants have one leaf, lift carefully, and pot singly into 3-inch pots; the same soil as used for sowing the seeds will do. When potted place in a warm frame, and near the glass, to prevent the plants from being drawn. Give a moderate amount of air through the day, but close early in the afternoon and give the plants a gentle sprinkling overhead. When the pots are full of roots they will require shifting into 5-inch pots; the soil for this potting should be a little rougher than what was used for the previous pottings; the same compost will do, but some well decomposed manure may be added. When potted, return the plants to the frame until the end of September, when they should be placed on shelves in a warm greenhouse, where they may remain until February, when some of them will be showing flower. All plants that are throwing up blooms should be removed to a cool house, where, if placed in an airy position and attention paid them as regards watering, they will continue in flower for many weeks. When the flowering is over, remove the plants to a cold frame and give water until the leaves begin to decay; then gradually withhold it, allowing the plants to rest until August. Then the established plants should be shaken out and repotted into the same sized pot; place in a cool frame and keep moist and close for a few days until commencing to grow, when air should be admitted freely. By the middle of September they will be growing freely, when some of the largest may be shifted into 7-inch pots and placed on shelves near the glass in the greenhouse. If seedlings are grown as well as old plants, the Cyclamen may be had in flower from November to May. The seed should be sown in March, but if home saved it is advisable to sow in August, or as soon as it is ripe.

OLITOR.

Notes from Laxenburg.—On a recent visit to the Imperial Gardens at Schonbrunn, I noticed in one of the cool houses several forced shrubs of *Prunus Mume*, which were a beautiful sheet of white. *Acacia vestita* climbing along the roof is very telling; used in this way its drooping flowers are best shown. Of New Holland plants noteworthy were *Hovea pungens*, with beautiful dark blue flowers; the rather rare *Banksia Caleyi*, and *Hakea Victoriae*—the latter has peculiarly formed, leathery leaves, with a silvery hue. A batch of young plants of *Telopea speciosissima* was in good health. As undergrowth near Tree Ferns, *Blechnum gracile* is well suited; young fronds

of this temperate-house Fern have a very attractive light rose colour. The old specimen of *Todea barbara* cultivated here reminds one greatly of the still larger specimen in the temperate house at Kew. In the Palm house are, amongst the general collection of Palms, Cycads, and Tree Ferns, conspicuous specimens of *Brownea Ariza*, *Curatella imperialis*, and *Astrapea Wallichii*.—LOUIS KROPATSCHEK.

Impatiens Jerdoniæ.—Although seldom met with in cultivation, this Balsam is one of the prettiest. An airy position in an intermediate house suits it admirably. It requires but very little root room, and seems to thrive best in a well-drained pan. It is a surface-rooter, very dwarf in habit, and the leaves are thickly set. As soon as the plants have finished flowering, water should be gradually withheld, when they will soon lose their leaves, and no more should be given them until they show signs of pushing in the spring. During their resting period care should be taken not to let the thick fleshy stems become too flabby, which may be remedied by giving them a little water.—F. S.

Growing Arum Lilies.—Several letters have appeared in THE GARDEN lately about Callas and their treatment. "J. G. H." says, in a recent issue (p. 163), that he had seen some plants grown in the same pots for three years and only top-dressed annually. I saw several hundreds in a house a few weeks before in 5-inch pots; they were only grown for Covent Garden. Many had two blooms, which would be expanded by Christmas. They had been treated thus: In May water was withheld for a week or so, but not to dry them up. They were then cut down and laid on their sides in a cool shady place out-doors. If they got very dry they were stood up and given a little water and laid down again. At the end of August they were stood up, a top-dressing of loam and manure given and watered. The cutting down seems out of the question for Callas, but they were looking well and flowering as stated.—C. JEFFRIES.

Winter-flowering Carnations.—In reference to Mr. Gilbert's experience with the above (p. 183), I think I may safely venture to say that, although he states that it is from practical experience that he writes, he has made some errors. I am not acquainted with all the varieties which are included in the dozen that he grew, but there are one or two which he failed to flower that I consider are among the best of the class for winter work, especially *Lucifer*. This bright scarlet variety has been flowering freely with us throughout the winter. Mr. Gilbert says his plants were duly stopped during May and June. This is sufficient to account for some of the varieties not flowering, for, although many of the sorts may be stopped in June, and will throw up fresh flowering stems in time to flower at mid-winter, it is not the case with all the sorts; in fact, I think there is little advantage in stopping any that are propagated so late as the end of March. If the plants are potted off as soon as sufficiently rooted, and exposed to plenty of fresh air before they get drawn, they will branch out naturally; and although the flower-stems may appear to run up too quickly, they will not be in flower much before the seasonable time, or if they do flower a little earlier than they are required, the succession flowers will come on better than if the plants had been stopped. I quite agree with Mr. Gilbert that Miss Jolliffe is the most useful of all the winter-flowering Carnations.—E.

SHORT NOTES.—STOVE AND GREENHOUSE.

Asparagus plumosus nanus.—Although this plant has been some time before the public, it is only lately that it has attained any great popularity. It is certainly very handsome. When well grown it appears to enjoy a moist stove temperature and rather dense shade. A fine specimen I saw lately had a quantity of seed-pods on it, but whether it will mature perfect seed or not I cannot say.—J. G. H.

Thrinax radiata.—Under this name Mr. Penfold has at Beddington House a most exquisite and graceful fan-leaved Palm, which we cannot believe bears its proper name, for *T. radiata* is but a synonym of *T. elegans*, and we are quite convinced that Mr. Penfold's Thrinax is not the plant which is usually found in English gardens under the name of *radiata*. The ample finely divided fan-shaped leaves which the plant in question produces, and its long, slender,

unarmed footstalks, quite destitute of the yellow band so characteristic of *T. elegans*, all point to its being something new.—G.

SEASONABLE WORK IN PLANT HOUSES.

CAMELLIAS.—Plants that are grown in pots and tubs should, as they go out of flower, be moved to a house where an intermediate temperature is kept up, with a moderately close atmosphere, syringing freely overhead once or twice a day. These plants are not unusually located in vinerias that happen to be at work whilst making their growth, but where they can have a house to themselves it is much better, as, though the young foliage is benefited by a little shade when the weather is bright, unless theinery happens to be so constructed as to admit more than an ordinary amount of light, and the vines thinner on the roof than usual, the Camellias do not get as much light as is necessary to promote robust, healthy growth. There are few hard-wooded plants the growth of which is more influenced by manurial stimulants than Camellias, but whatever is used, either in the form of manure-water or surface-dressings of concentrated manure, its application should be confined to the time when the plants are about to push their shoots and onwards whilst the growth is being formed. When Camellias are healthy, their roots begin to move freely a short time before the top-growth commences, and I have proved by experience that manurial assistance given to them at this time is much more effectual than when its application is withheld until top-growth has begun. Manure-water made from horse-droppings, with some soot stirred up in it, allowing all the solid matter to settle, answers for these plants in every way. If at all affected with scale, especially the white species of this troublesome insect, the plants should be gone over before the young growth moves, by which much labour later on will be saved.

BILLBERGIIAS.—The handsome flowers and distinct appearance of these plants are such as to commend them to all cultivators who have a warm stove. The little room they occupy is not the least of their merits. Most of the species are epiphytal in their native countries—a fact that is not always kept in mind, and to this is attributable the indifferent success that sometimes attends their cultivation, as, in common with other plants of a like nature if potted in close adhesive soil, their roots do not take kindly to it. They succeed in loam, but it should be of an open, turfy nature, with enough sand in it to keep the whole porous. They are increased by suckers, which are produced from the base of the crowns that have flowered. It is well to allow the suckers time to get strong before removing them from the old plants, otherwise it takes long to get them up in size. Suckers that were produced by plants that bloomed in the early part of last summer should now be large enough for removal; they are best slipped off from the stools: in some cases they will have more or less roots to them, in which case they will grow away at once. But, whether in this condition or devoid of roots, place them singly in pots just large enough to hold them. If they can be accommodated with a brisk growing heat they will soon get established. Later on, when the roots have got well hold of the soil, give pots a size or two larger. In the matters of air, moisture, and warmth, ordinary stove treatment is all they require, giving a little shade in bright weather.

ECHMEAS.—These pretty plants are nearly allied to the Billbergias, and succeed under much the same kind of treatment. The small-growing *E. miniata* and its variety *E. discolor* are amongst the most useful small decorative stove plants. The coral-red spikes that bear the flowers retain their bright colour and freshness for many weeks after the flowers have faded, so far that close inspection is required to ascertain whether the plants have bloomed, or are coming into flower. For standing about in a warm conservatory during the summer months they are very effective. Echmeas are increased by suckers like the Billbergias, and they should be taken off and

potted singly in the way advised for Billbergias. Fibrous peat with some crocks, or charcoal, and a little sand, answers for them, treating in other respects as advised for the Billbergias. Though these, like the last-named plants, cannot be increased at the rate which things that produce cuttings in quantity can, still a stock may soon be got up, as the old stools, if well cared for, will throw up additional suckers after the first lot have been taken off.

GARDENIAS.—Amongst the various kinds of these plants known to cultivators *G. florida* intermediate and *G. radicans* are the most generally useful; the latter, although its flowers are much smaller than those of the former, is a desirable sort on account of the little room it occupies and the profusion of flowers it bears. Old plants of any of the kinds that have got leggy may be cut close in now; in a warm stove they will break fresh growth at once, when they may be turned out of the pots and have a portion of the old soil shaken away, replacing it with new and giving pots proportionate to the size of the plants. Gardenias can be kept going in a moderately free condition with less root room than many plants that are of a similarly vigorous nature, but to obtain the maximum quantity of flowers they must have pots proportionate to their size. *G. radicans* being, as already said, a much smaller and slower grower, it does not require nearly such large pots. *G. citriodora* is quite distinct in habit of growth and also in the character of its flowers, which resemble Orange-blossom in appearance more than they do the kinds first named. Where fragrant flowers are much in demand for cutting, this species should find a place; so naturally free in blooming is it, that little plants in 5-inch or 6-inch pots produce flowers on every bit of growth they make. Plants that were struck from cuttings early last spring will now require a little more pot room; peat where it can be had of good quality is best for this, as also for the other sorts. Cuttings of the different kinds named should be put in to strike—they are amongst the easiest of stove subjects to propagate. The cuttings need not be confined to small bits of the shoots, as good-sized branches will root in a short time if they are kept moist, close, warm, and shaded.

PALMS.—These plants, especially the species that require a stove or an intermediate temperature, are often allowed more root-room than it is either necessary or expedient to give them, inasmuch that for ordinary decorative purposes, after the plants have attained a useful size, the object generally is to treat them so as to prevent their out-growing the space that can be allowed them, and when they have larger pots than are requisite to keep them in a healthy condition, many of the species soon attain an unmanageable size. Still, though it is advisable to thus limit the root-space so far as can be done without injuring the plants, it is scarcely necessary to say that it is possible to go too far in this direction, in which case the leaves assume a yellow, starved appearance. Much may be done to give the foliage its wonted colour by the use of manure water regularly applied during the growing season. When it becomes necessary to re-pot, early in the spring is the best time to carry out the work. Palms will grow in almost any sort of soil, but rich, yellow loam is the best, adding a little sand; in potting, make the material quite solid in the pots, being particular that the drainage is efficient, so that the large amount of water which the plants require can pass away freely.

GIVING AIR IN COLD WEATHER.—There is no time of the year when it is so necessary to use caution in giving air to plant-houses as during this and the following month, when the weather is so changeable. In stoves where the young foliage is, as a matter of course, tender, the effect of a rush of cold air coming in contact with it is highly injurious. Except when the air is quite still, even when the sun is powerful, it is better to only open the roof ventilators, and these only to a moderate extent, for, as often happens on bright, cloudless days, the wind is keen. When such is the case

it is better to let the temperature run up considerably than admit air in large volumes. Greenhouse plants are less tender than the occupants of the stove, but the principle holds good with them, as they should never be subjected to cold draughts. When side air is given in cold spring weather, it should always be admitted at the opposite side to that at which the wind is blowing. T. B.

TREES AND SHRUBS.

W. GOLDRING.

THE NORWAY SPRUCE.

THERE ARE various opinions as to the position of the Norway Spruce (*Abies excelsa*) among ornamental trees. Some have assigned it a high place, while others have condemned it. We have here to consider its merits as a garden or park tree, leaving out of the question its value as a timber tree, which has often been discussed in *Woods and Forests*. As a garden tree the Norway Spruce is undeniably neglected, not because it is less ornamental than newer or less common Spruces, but because it is customarily planted as a forest tree; there is, however, no comparison between a plantation Spruce and a garden Spruce well cultivated, *i.e.*, planted in the best of soils and sheltered from cutting winds. The Spruce will not stand much exposure, though it should be allowed plenty of room in which to develop itself on all sides. Thus circumstanced one can have a beautiful tree symmetrical in outline, but still beautiful, owing to the graceful way in which the branches arrange themselves in regular tiers with the slender twigs drooping in a handsome manner. I was lately so impressed with the elegance and grandeur of some well cultivated Spruces, that I am determined to plant some in similar positions whenever I have an opportunity. The Spruces to which I allude form a group of about half a dozen planted in an irregular way, with ample space allowed for each. They were of various heights, the tallest being about 40 feet high, the shortest about 15 feet high. All were in the best of health, their lower branches sweeping the lawn, and each had a trunk as straight as a mast, terminated by a stout, erect leader. The position of this particular group was between two hills, and therefore sheltered; the soil was almost continually moist, but being of a light, sandy character the water did not become stagnated. On the same estate I saw other fine Spruces, not in a moist spot, but where a bed of clay cropped out; these were accompanied by some grand Oaks, a charming combination, the green of the Spruces contrasting strikingly in summer with the heavier green of the Oaks; while in winter the bare look of the Oaks was thereby diminished. All who see the group of Spruces which I have attempted to describe are charmed with them, especially when furnished with a profuse crop of pendulous russet cones. A Norway Spruce is generally most beautiful when between 20 feet and 40 feet high. In its very young or "Christmas-tree" state it is not very handsome, nor is it when 80 feet or 100 feet high, for then it is commonly bare of branches below, thus interrupting the symmetry of outline, and giving the tree a ragged appearance. One can always tell a Spruce in a plantation a mile distant, as its spire of branches shoots up above all its companions; and at no age can it be called a picturesque tree. The Spruce is a rapid grower in the most favourable soils and positions, especially after it has grown out of its juvenile stage—that is, before the plants are under 3 feet in height. After the seedlings have reached this height, they shoot up at the rate of 2 feet and even 3 feet a year. It does not attain to the great height one sees in

Norway and other parts of Europe, where it reaches as much as 150 feet high, with trunks as straight as a mast. The accompanying illustration represents a finely grown Spruce with the characteristic conical growth. The tree at the time the drawing was made was growing at Studley, in Yorkshire, and was 132 feet in height, with a diameter of trunk of 6½ feet, and the spread of branches was 39 feet.

In order to obtain fine Norway Spruces for ornamental effect care should be taken in selecting the young plants in the nursery, as it is useless to plant any that have not been properly treated in a young state. The selected trees should be of vigorous growth with every whorl

Norway Spruce (*Abies excelsa*).

of branches perfect, for if any of these are crippled when young the symmetry of the plant is spoilt. The best of all are, of course, Nature-sown seedlings, but these are not often to be found in the exact spots where an ornamental effect is desired, but if one could afford to wait a few years, one might sow seed in the places where a group of Spruces would be appropriate, and leave the seedlings to grow up undisturbed. It is not difficult to obtain Spruces that have been well cared for in the nursing stage, and, moreover, at a very cheap rate. One can understand that to advocate the planting of the common Spruce for ornament will not be regarded favourably by nurserymen, who pay so much attention to exotic Conifers of doubtful

hardiness and merit, but this plea on behalf of the Spruce need not interfere in any way with the popularity of other kinds of Conifers. There is no necessity to go into a detailed description of such a familiar tree as the Spruce, but how it differs from its near allies, such as *A. alba nigra* and others, will be explained when we shall refer to those Firs. There is a host of varieties of *A. excelsa* all differing from the typical form, and some so widely that one would almost regard them as distinct species. Some of these varieties are of considerable ornamental value, particularly the dwarf varieties, such as *clan-brasiliana* and *pigmaea*, and to these we shall allude at some other time.

Spiræa Bumalda.—This little shrub is looked upon as one of the best new things that have been introduced lately, and we hear of enormous quantities being sold at the large tree nurseries, notwithstanding the fact that it is scarcely known in a general way. In fact, everybody who sees it in flower wants it, and at the exhibitions last year and the year before it was noticed a good deal. It is a very dwarf plant, not more than 1 foot or so high, and always of compact growth. It may be best described as a dwarf form of the well-known *S. callosa*, as it has similar dense flower clusters of a rich carmine pink colour. It is a capital shrub for the rock garden as well as the shrubbery. It must not be planted where, from its small size, it would be apt to be overgrown by larger growing things.

Prunus Pissardi forced.—A good deal has been written and said about the beauty of this Plum as regards its foliage, but little has been seen or heard of its flowers, but it is probable that now it has proved so amenable to early forcing it will become as popular for the greenhouse in early spring as it is in the open air in summer. On Tuesday last a group of plants of it was shown by Messrs. Paul, of Cheshunt, which was the admiration of everyone, and not a few were surprised to see such a lovely new shrub. The flowers are produced in great profusion; they are about half an inch across, and shaped as other Cherry blossoms. They are of a delicate blush-white, while the unfolding leaves are of a ruddy tinge, but not so deep as they will become later on. The group had an extremely pretty effect, and one can imagine how charming this *Prunus* would be intermixed in a tasteful way with other plants. The plant was certificated some time ago, when it was exhibited for the sake of its fine foliage; consequently the floral committee could not award a certificate to the plant in bloom, as they undoubtedly would have done. On seeing the tree in bloom one could at once see how nearly the flowers resemble those of *Prunus cerasifera*, of which old and well-known species it is a variety. Moreover, it does not come true from seeds, as green-leaved seedlings have been produced.

Bambusa Metake.—There was a time, and that not very long ago, when it was a difficult and expensive matter to obtain a Japanese Bamboo at a nursery. It is different now that the great importance of the plant has been fully recognised, and since it has been found to be thoroughly hardy, easily grown, and rapid in growth. I was astonished, the other day, in seeing it grown by the acre in the Knap Hill Nursery, and perhaps nowhere beyond Japan can such a sight as this be seen. The thicket of wand-like stems, some rising 6 feet or more high, rattle in the wind like a plantation of Maize or ripe corn, and the pale green of the foliage is unlike anything else in a similar way. It is the only Bamboo grown on a large scale at Knap Hill, for the others are tender, and nothing that is not of undoubted hardiness receives much attention in this nursery. With the merits of this Bamboo everybody by this time must be well acquainted. It may be too much to say that there is no pretty garden without a Bamboo, but it may be fairly said that nothing helps so much to make a garden pretty as vigorous plants of *Bambusa Metake*.

A paper by Mr. John Wragg, "Best Conifers of the West," brought out renewed commendation of the white and silver Spruce, the white and red

Pines, and Platte red Cedar. The silvery expression of the Cedars, Spruces, and Firs of Colorado brought out the point that a silvery expression of plants was common in dry inter-continental regions with herbaceous and ligneous plants. In far Eastern Europe and Central Asia, the Poplars, Willows, Pears, wild Olive, and most other trees were silvery in expression, and a thick pubescence was found on the leaves and buds of Apple trees, and a rich bloom on the fruit.—*State Register's Report of Horticultural Meeting.*

Daphne Blagayana—This low-growing Daphne is essentially a rockwork plant, and in a sheltered nook thereof is now in flower. It is of rather loose, rambling habit, is furnished with neat deep green leaves, and bears clusters of pure white blossoms which are agreeably scented. A distinct feature is imparted by a collar like row of leaves that surround each head of bloom, in a manner, as far as I know, peculiar to this species. It is a plant that is not vigorous enough for association with many of our shrubs, but in such a spot as above indicated is most pleasing.—H. P.

Osmanthus ilicifolius.—This is a capital evergreen shrub for planting in town gardens. Its glossy dark green leaves are less affected by fog and soot than those of most plants, and it thrives well in every town garden in which I have seen it tried. It is especially suitable for massing in small beds, as its natural habit is spreading, and it can be kept within bounds by pinching or pruning at almost any time. The bronze tint in the young shoots and foliage gives a nice contrast to the dark green of the older leaves. If some peat can be worked into the soil when planting, it will assist growth, but it is not absolutely necessary, for the plants do well in any fairly light soil.—C. T.

Lonicera fragrantissima. The bright weather we have experienced during the last week has effected a great change in this Honeysuckle, for it is now completely wreathed with its deliciously fragrant blossoms, and when the sun is shining the odour is perceptible at some distance. It is strange that this and *Chimonanthus fragrans*, two of the most sweet-scented of wall shrubs, should unfold their blooms during the dull winter season, at which time they are about the only flowering representatives of all our wealth of shrubs. Both are far more suited for planting against a wall than in the open ground, but if grown in pots they will flower well under glass, especially the Honeysuckle, and are additionally welcome by reason of their agreeable odour. Another *Lonicera*, viz., *Lonicera Standishi*, is often confounded with *Lonicera fragrantissima*, but differs in many respects from that kind, for while *Lonicera fragrantissima* is strictly a climber, the other is quite a bush. In *Lonicera Standishi*, too, the leaves are hairy, which is not the case with the other. In both, however, the flowers are pure white and possess the same agreeable perfume.—H. P.

Butcher's Broom (p. 193)—Mr. Wilks asks "W. G." whether he has ever seen this fruiting freely in England. He will, no doubt, answer for himself, but if he has not seen it I can tell him where, at some time, he will most likely be able to do so. With us the plant grows pretty much as Mr. Wilks describes it—"morose, forbidding-looking, huddled, and drawn together," and I was, on this account, all the more astonished, one day, to see it in the Beech woods on the chalk downs of this country "bright, cheerful, spreading, and covered with exquisite big berries." It was in broad masses under the Beech trees, evidently quite happy, and certainly a most pleasing object. So I always believed since then that it was fond of chalk or lime, as well as warmth. The berries, when produced freely, are very striking, from their size, colour, and peculiar position.—C. R. S. D., *Sussex*.

—Butcher's Broom fruits here freely, and the large red berries have had a charming appearance this winter peeping through the snow. It is valuable for cutting, as the berries last a long time before they begin to shrivel. I have two varieties; the one that

bears fruit grows close and stiff and the foliage is dark green, the other, which I call the male, is of rather taller growth, and the foliage is of rather a lighter green. In planting I always put a so-called male plant about 50 yards or 60 yards off the fruiting kind. I have seen grand clumps of the fruiting kind in woods and ornamental grounds without ever seeing a single berry on them, from which I have always concluded that there could not have been a male variety in the locality. If not, why does not Mr. Wilks' plants fruit, as the climate around Croydon is much warmer than that here in East Norfolk where we suffer much from cold winds in spring and autumn? I wonder Butcher's Broom is not grown more than it is, as it will accommodate itself to any situation under the shade or in the open, also to any soil. I have some plants growing in pure sand and some in stiff clay, but when once planted I say let it run in where it is, as it does not take kindly to being shifted too often. It has one fault, and that is that nearly every year a shoot or two will die off from some cause which makes it look shabby until they are cut out.—J. E. SENDALL, *Grundall, Norwich*.

KITCHEN GARDEN.

W. WILDSMITH.

KITCHEN GARDEN EDGINGS.

THE rigid economiser of land and labour will perhaps whisper, why have edgings at all? The crops will be just as good without them, a conclusion that I venture to question, on the ground that persons who are careless in regard to appearances, or what in this instance may be called the frame of the picture, are not in a general way the best of cultivators, for carelessness in regard to trifles soon begets carelessness in larger matters. There are, of course, exceptions, but in regard to private gardens, so far as my own observations extend, I have invariably found the highest cultivation in association with well kept walks and edgings; but even supposing that was not the fact, a man with any pretension to orderliness must always feel vexed in spirit so long as a kitchen garden is without edgings. It may be that my own notions are too refined, tending as they undoubtedly do in the direction of favouring the maintenance of good edgings, walks, &c., even at the risk of some slight neglect of the vegetable crops, for the probability is that such defect would be hidden by the excellence of the marginal enclosures. In regard to kinds of edgings, there is no question that the various descriptions of tile and stone edgings are the best from a utilitarian point of view, as after they are once fixed no further labour in reference to them is needed; such edgings afford no harbour for slugs and grubs, and they always look neat, but for all that I cannot recommend such edgings, as in my opinion a live edging is much to be preferred to one of either tile or stone, and in spite of the harbour which such edgings afford for slugs and the clipping required, I pronounce Box to be my especial favourite for kitchen gardens. The labour of keeping it is not nearly so formidable as some make out; it virtually only requires to be trimmed or clipped once a year—any time in June—and with care not to wheel or trample it down, the repairs which such edgings require in a large garden during winter do not take up more than a couple of days. Common Thrift makes an excellent edging, but it harbours slugs even more than Box, and since tiles have come into vogue its use on that account has declined. The labour needed to keep it in order is but little, and as that little can be performed during winter when work is least pressing, any objection to it under this head is not worth considering. The labour here alluded to is the lifting, dividing, and re-planting every third year, as in that time some of the plants outrun others in growth and create inequalities.

The common and variegated Thymes are both suitable edging plants for kitchen gardens, but, in order to keep them thick and of neat appearance, they must be clipped twice during the summer, *i.e.*, in the middle of May and the middle of July; but the clipping does not take up nearly the time that Box clipping does, and a gap can more readily be made good; yet another advantage is, that Thyme will flourish in soils in which Box will not thrive. The small variegated *Eutonymus radicans* I have seen used on a small scale, and right well it looked—so well, in fact, that I have a strong desire for an opportunity to plant such an edging, though, by the way, it was cuttings, not plants, with which the edging was first formed, and which, as soon as struck and had made 4 inches of new growth, had their points taken out to induce the formation of side or lateral growths; afterwards the plants were treated in every way the same as Box. The fine, wiry Grass called *Festuca glauca* I have tried as an edging on a small scale, and right well it did in damp and shaded positions; but on dry ground and exposed to the sun it was a failure, being like so much dried-up Grass that was only fit for the fire. I would only recommend it as an edging for heavy soils where it might be expected to look tidy all the year round. Were it not for the labour of clipping it during the busy summer season, the Japanese Honeysuckle (*Lonicera reticulata aurea*) would be worthy of notice, but the labour needed to keep it properly excluded it from use in this connection; but it is the perfection of an edging plant for flower beds, and has no rival as a trailer for drooping over the edges of vases. This exhausts my list of the various permanent edgings for the kitchen garden. There are several others of a more transitory nature, allusion to which I defer to another time.

BRUSSELS SPROUTS.

THERE is no other winter green so hardy and, at the same time, so valuable and so much appreciated as the Brussels Sprout. The late severe weather has again proved, if further proof were required, how useful this Sprout is, and how very desirable it is to have a good breadth of it planted to come in after Christmas, for though Brussels Sprouts are very useful in autumn and early winter, they are simply indispensable now, when so many greens less hardy in constitution have been killed by the frost. The first sowing should be made now in a box under glass where there is a little warmth. The produce of this sowing will be pricked off when large enough and planted out finally in May in rows 2½ feet apart, and they will come into use in autumn, and will keep, if not wanted then, until a demand arises for them. But usually a dish of close, firm, moderate-sized Sprouts are appreciated as soon as the supply of Green Peas fails.

THE MAIN CROP should be sown thinly in the open ground about the third week in March in drills 9 inches apart, covering the seeds from a quarter to half an inch deep. Seed-eating birds are very fond of the seeds, and they should either be protected with nets or be dressed with red lead. The last named plan is a sure remedy against birds and mice. Place the seeds in a saucer, damp them by sprinkling a little water over them, shake the lead, which is a red powder, over them, and stir the seeds about with a stick until all have taken on a thin coat of lead. The seeds are then sown thinly in the drills, covered with soil with the feet and the bed raked smooth. It must not be forgotten that red lead is a poison; wash the hands carefully immediately after sowing the seeds. The plants from this sowing should be planted in the open quarter in rows 2½ feet apart and 2 feet apart in the rows. There is nothing gained by planting closer together, as the leaves must have space to develop in order to insure a full crop of close, firm Sprouts. Plant out a good

breadth, as I never remember hearing anyone say they had too many Brussels Sprouts.

A LATE SOWING may be made for spring use about the middle of April, and the plants from this sowing may be set out in July in rows 2 feet apart and 1½ feet asunder in the rows. In the case of a severe winter coming, this crop will be found very valuable. Keep the hoe going between the plants until they are a foot or so high, then earth them up as a shelter and support to the stems. When the stem leaves change colour, remove them, but do not cut out the leaders till they can be made available for use as Cabbages after Christmas.

VARIETIES.—It is very important that a well selected strain only should be grown, as there are many spurious and inferior strains in the market. All the great seed firms have selections of their own, and one may safely trust that belonging to any of them. The Aigburth is a very good stock. It is a good plan when a good stock has been secured to save seeds. A dozen plants will produce seeds enough to last five or six years.

E. HORDAY.

VEGETABLE MARROWS, AND HOW TO GROW THEM.

MANY vegetables which are highly prized in the early spring and summer months become a drug in the market before the season is over, and amongst these must be classed Vegetable Marrows, as in August and September they do not fetch the price of Turnips. But for all that, they are not, in my opinion, used so much as they should be, or as they would be, if the public supply was confined to the best varieties. Size is the great object with ordinary market dealers; quality is the only point which will increase their use and give constant satisfaction. There is nothing one tires of sooner than large coarse Marrows, but the small delicate-flavoured ones are excellent at all times, and a desire for them exists always. But it is not only in markets that the large ones find favour, as they are often grown in gardens where choice vegetables are most desired, and the consequence is that the Marrows are rejected, and most of them ripen on the plant, and are never used. It may be asserted that there are plenty of other good vegetables ready at the time the Marrows are plentiful, and this is so, but I never knew a time when a change of vegetables was not acceptable; the variety could not be too extensive, and if the Marrows were good they would be used frequently every week, in spite of the abundance of Peas and Kidney Beans. There is, too, a grand opening for Marrows in the early part of the season, and if they were grown to fruit during May and June, they would then be found invaluable. Marrows, as a rule, are not grown to fruit before July, but there is no reason whatever why they should not be secured in the first week in May. It might be a difficult matter to get the large fruiting varieties to produce their semi-pumpkin-like fruits by that time, but the small sorts are more fruitful early in the season and at all times, and my remarks only apply to this class. By sowing seed now, growing the plants on in a temperature of 65° until they are 1 foot or 18 inches in height, and then planting them out on a slight hotbed and under a rough frame and glass-light, they will fruit at a very early stage of their growth. The seed should be sown singly in small pots, and as the plants grow they may be potted into larger ones, but do not use very rich soil at any time, as this only produces a soft, luxuriant growth; whereas it is a hardy, short-jointed shoot that always fruits most freely and soonest. Many growers ruin their Marrows for early fruiting by growing them in too rich soil, as thus they become smothered with large leaves and produce only male flowers, and do not fruit freely until they have exhausted the bulk of their rich rooting material. We have had them fruit in a 6-inch pot, and not 6 inches from the rim, and this indicated clearly enough that to fruit them early luxuriant growth is not wanted. They grow very freely in a high temperature, but a moderate heat is best for them, and to ensure them being dwarf they

should always be kept near the glass. They are as easily fruited by May as a Cucumber; nor do they require so much heat as Cucumbers do. Frosts or cutting winds they will not bear, but anything except these will agree with them. Another good way of fruiting them early is to pot and repot until they are in 10-inch pots; then plunge them in a small hot-bed under a frame, and the roots being thus confined, fruit will quickly form at every joint. Short-jointed shoots of medium strength are always the most prolific, and so long as these are produced there is little danger of the plants proving unfruitful. In raising Vegetable Marrow plants for general open-air culture, they are always best when raised singly in small pots. About the end of March is early enough to sow them, as the plants will then be in good time for planting out by the middle of May, and they are not safe before that time. If 3 inch pots are drained and half filled with good soil, a seed placed in each and covered over 1 inch or so, it will germinate in any place under glass, and if grown on like a bedding Geranium will succeed admirably. I have condemned rich soil for plants in frames, and I do the same in the case of plants in the open. In this position we often hear of fruit forming, but refusing to swell, and falling off before it has gained any size, and the cause of this is neither more nor less than growing them in too rich soil, as the luxuriant foliage overshadows everything, and when the fruit-flowers are open they are so much hidden from sun and air that they are never perfectly fertilised; hence the reason of their falling off prematurely.

THE RAISER OF PEN-Y-BYD.

Mushroom culture in Pea trenches.—Has any reader of THE GARDEN tried this method of growing Mushrooms? We have obtained a plentiful supply during the summer and autumn by the following plan. When preparing the trenches for Peas, about 8 inches of stable manure, half rotted, is put in and well trodden down, and on this is placed, about every 2 feet, pieces of Mushroom spawn about the size of a hen's egg. Part of the soil is then returned, and the Peas sown as required. The copious supplies of water required by the Peas, and the shade they afford, seem just to suit the Mushroom spawn, for Mushrooms begin to appear before the Peas are done; and if the sticks and haulms are carefully removed and water given, the supply may be kept up well into the autumn.—W. JEFF, *Tophill, Eastbourne.*

Thin Mushroom beds.—"G. S." (p. 216), who has successfully grown Mushrooms on a very shallow bed, argues therefrom that beds need not be a foot thick, but he forgets that the employment of artificial heat in his case does away with the necessity for thick beds. My note on the subject to which he refers related to Mushroom beds in unheated houses, sheds, or cellars, that, although not built for Mushroom growing, are frequently utilised for that purpose; and I feel sure that in the majority of cases it is desirable to err rather on the side of having too much than too little bulk in the beds. It is impossible to avoid sudden fluctuations of temperature in beds less than a foot thick. Market growers even who carefully study the cost of production do not find that shallow beds pay; on the contrary, they rely on a good body of material to produce a good crop.—J. G. H.

SHORT NOTES.—KITCHEN.

The old Ashleaf Potato.—We have early Potatoes without stint; some of them may have been new at one time, but many of them are old ones named and renamed, but amongst them all the old Ashleaf Kidney appears to retain its name and character, and when true there is no better early Potato in cultivation.—In fact, it is the best; it is dwarf, bears heavily, and the quality of the tubers in all soils is excellent.—J. Mear, *Margton, Port Talbot.*

Asphaltic walks.—Will some of the readers of THE GARDEN kindly give me their advice as to which is the best mode of constructing asphaltic walks? I have tried by boiling 1 lb. of pitch to every gallon of gas tar, and mixing it thoroughly with ashes, leaving it in a heap for two or three weeks before spreading it on the walks, but it does not seem to set well. Would it set better by spreading it as soon as mixed before getting cold?—J. R. WHITEHEAD.

Firm soil around young vegetables is of the highest importance, for if they are loose the drying winds of March will parch them up. At this season all beds and borders should be gone over, and any plants that have been loosened by frost should be firmly pressed into the soil.

Autumn-planted Strawberries, too, that delight in a firm root-run should have the soil well trodden down all over the bed as soon as it is dry on the surface. In the kitchen garden such plants as autumn-sown Cabbages, Lettices, &c., are very liable to suffer in this way and perish before they can get fresh root-hold, unless they are pressed firmly into the soil.—J. G. H.

Carrot Red Valery.—By the introduction of that fine French kind, the Red Valery, into this country, and for which I presume we are indebted to Messrs. Vilmorin & Co., of Paris, we have obtained a Carrot which seems to be in form, beauty, and texture the very perfection of this root. I do not assume that the new Intermediate, the Matchless, or some others just like the Valery are identical. It is not of much consequence, so long as we get a good thing, and not worth quarrelling about. That this new comer will supplant the shorter, though still excellent, Intermediate, there can be little doubt, but being better will presently hold the field, as a general main-crop Carrot it can hardly be surpassed. The long Carrots are hardly so popular as they once were; they come out very handsome and clean from the deep Surrey sands, but give, as a rule, too much bone relative to flesh. I have seen the Long Surrey grown in the neighbourhood of Faruham of wonderful length, and when set out in flat or fan-shaped bunches, quite startling in appearance, but such "sticks" are not desirable. The Altringham has also enjoyed a good reputation, but it thrusts a coloured top up above the soil, the which is waste. Probably the three most useful Carrots we have are Early French Horn, short, early and easily forced, or quickly produced even in cold frames; Early Nantes, so excellent and fleshy, and good for successional sowings on warm borders; and Valery, New Intermediate, Matchless, or however known, for main crops.—A. D.

KITCHEN GARDEN NOTES.

SEED SOWING.—February is said to "fill the dyke either with black or white," but this year shows us that proverbs are not to be trusted, 0.35 inches being our total rainfall for that month; the consequence is the soil is in about the best condition for sowing seeds that I have ever known it to be, and main crops of Parsnips, Onions, and good succession lots of Peas ought to be in by this time. There is just a chance that the tempting state of the soil may not turn out to be an unmixed good, as the probability is that inexperienced hands may be induced to sow all and sundry, with a view, as they think, of getting ahead with their work. To such, I would say, beware, and quote another proverb, which invariably turns out to be true, viz., "the more haste the less speed." Yes, it is very unwise to sow a large plot of Turnips or Beet and large-rooted types of Carrots thus early, for they will certainly run to seed; again, by sowing unnecessarily large successions of Peas, Broad Beans, Lettuce, Radish, and Spinach, there will presently be the difficulty of finding ground sufficient for successional sowings to maintain a constant supply throughout the season. The produce may not be difficult to get rid of, but I always think that sufficient is better than an overplus; besides, vegetables are always best when used as soon as ready, and on that account successional sowings in quantity according to the demand is the best of all rules to adhere to. I would advise that a moderately large breadth of the warmest border be sown with Early Nantes or Early Horn Carrot, Lettuce, Radish, and just a few Early Munich Turnips, and what more of similar ground can be spared should be devoted to early varieties of Potatoes. These will all come in immediately after the supplies from pits, frames, and artificially constructed frames are exhausted. I ought to add that any labour that can be devoted at time of sowing to scattering in the drills, either before or after the seeds are sown, any material distasteful to birds will be labour well spent. We use soot, wood-ashes, old mortar scraps, and artificial manures, each kind according as our judgment deems it likely to be of greatest service to each particular vegetable. Wood-ashes are invaluable for Turnips and Radishes, soot for Lettuces and Potatoes, and either guano or Beeson's manure for Carrots, Peas, and French Beans; mortar scraps are a certain preventive of

club in Cauliflower and Brussels Sprouts—in fact, in the case of all the Cabbage tribe.

GOOD VEGETABLES.—The late severe and long-continued snowstorm was, according to some, myself included, to end in there being no supplies for the kitchen; all must perish. Well, the mercury of one's temperament, I suppose, cannot be always stationary, and now that it has regained its normal state, we see how unfounded were our fears. All root crops are still extra succulent, owing, I suppose, really to the cold winter, which was to kill all. Let me here note all the kinds we now have in use, adding a word or two as to how they were wintered. Carrots, Intermediate, are as sweet and juicy as in autumn. They were left in the ground till December, then lifted, left a day or two in the shed to dry, and finally stacked closely together in a cool frost-proof collar. Beet-root is still perfect in quality—not a bit shrunken. This we lifted in November, twisted off the foliage, and served exactly the same as Carrots. Parsnips, I think, must be better than usual, for I never could relish them till this season. These were wintered in the ground and only lifted some three weeks ago. We spread a little Braeken over them, but I question whether it did any good, as the snow caused it to rot, and therefrom decay started at the crown in the case of some of them. We dug them up as soon as new growth was visible, and they are now stored dry in the cellar with Carrots and Beet. Jerusalem Artichokes are super-excellent and more than well appreciated, as our rapidly diminishing store shows. These were left in the ground all the winter, and only lifted a few weeks since, because necessity compelled us to plant them on the same ground again; so it was trenched and manured. This done the plot was at once replanted. This we did some five weeks since, but it is not too late to plant now.

CELERY is still very good and much relished as a second course vegetable. The snow did this far more damage than frost, as its weight completely flattened down the Braeken covering we had applied, and before it could be uncovered all the large outer foliage was in an advanced state of rotteness. We cut away every bit that could be seen, and raked away every particle of decaying matter with the result that, though not quite stopped, the decay has been but little. The recent severe frosts have hindered new growth starting. Once this is visible we shall lift the whole, heel it in under a north wall with some already lifted, because ground was wanted, and there it will keep in perfect condition so long as our necessarily limited supply will hold out. Turnips at last have turned round: the bulbs are fine and look very tempting, but when cut the flesh looks near akin to a white sponge; but what matter, they are still of the utmost value, and produce a quantity of greens of the best quality that do us excellent service alternately with tops of Brussels Sprouts, Cottagers' Kale, and Rape. The above constitutes the whole of our vegetable *menu* of open-air production, to which have to be added from forcing quarters French Beans, Asparagus, and Seakale.

CAULIFLOWER AND ALLIED VEGETABLES—Notwithstanding our present unexpected good supplies, as the foregoing note shows, it will not do to rest and be thankful; the busy springtime is upon us, root stores will get exhausted, and we must now look ahead. Cauliflowers are an important crop; we planted a few out too soon, and they are not now so good as when put out weeks ago; however it benefited those left in the handlights, so that it is not all loss. These now should have the lids constantly off in the daytime; keep down slugs by dustings of soot, lime, or a-hes. Plant out from frames on to a warm border in deep drills—for shelter—18 inches by 12 inches apart for earliest dwarf kinds, but 2 feet by 15 inches for the larger. Lift with balls of earth adhering to the plants and plant with trowels, when the plants will show but little signs of having been moved, and, as a matter of course, the heads will be ready all the earlier. If autumn-planted Cabbages have suffered, fill up the vacancies with

the best plants at command; never use spring-sown plants with these; it only makes the plot look higgledy-piggledy. I prefer to lift a row from the old plot to make good the others, provided a supply of plants of the same sowing cannot be had. As soon as the Cabbage and Coleworts that were raised in heat and pricked out in frames are sizeable for planting out it ought to be done. The Coleworts will make a fine succession to the autumn plot of Cabbages, and by the time they are exhausted the spring-sown Cabbages will be ready. I do not write for market growers, hence my advice to grow only sufficient, and decide the amount of such sufficiency by taking into account that at the time these will be ready there will be Peas, young Carrots, Cauliflowers, Broad Beans, Spinach, and abundance of new Potatoes. Scotch or Curled Kale, as well as Asparagus Kale, are breaking into renewed growth, and shortly nice sprouts will be obtainable throughout the entire length of their stems, which, having got loosened by frost, have been reformed in the soil by treading round them, and the entire plantation hoed and mulched with half-rotted manure. Broccoli we have attempted to do nothing to as yet, for decay is still going on, but when this has ceased we shall have a final clearance of all dead leaves and freshen up the ground by hoeing between the rows.

PEAS.—We have a quantity in pots that ought to be planted out, but the nightly frosts of from 6° to 10° deter us; ground and trenches are ready, and soon as there are indications of milder weather the work will be done. There are about nine Peas in a 3-inch pot, and each pot will be planted a foot apart, without breaking the roots at all. The trenches are 6 inches deep, and set as wind-guards, together with a good allowance of evergreen spray that will be placed at base of supporting sticks soon as planting is finished. I ought to have said that a good dressing with a mixture of soot, wood ashes, and lime should first be applied; and if needs be, to keep away birds, the soot dressing will be repeated as often as may be found necessary. The sorts we have sown in the open ground for second and third succession supplies are Advance, Best of All, Criterion, Telephone, and Veitch's Perfection—all good varieties—and by sowing several sorts at same time there is greater certainty of a continued succession, as no two sorts are ready on exactly the same date. The Peas already above ground are earthed up and well sheltered with twiggy Hazel sticks, lined at bottom with Yew branches; the latter will be pulled away as soon as the plants have gained strength, and got well inured to bear full exposure.

TOMATOES, CAPSICUMS, AND CHILLIES.—Our first batch of Tomatoes is now ready for potting into the fruiting size—11-inch pots. We pot firmly, in not very rich soil, else the tendency is to wood-growth rather than to fruiting. Soon, however, as a good set of fruit has formed, manurial waterings are given about thrice a week, and oftener if needs be. The plants are now in a Cucumber house, where a temperature of 65° is kept up and plenty of moisture in the atmosphere, and, being near the glass, the growth is all that can be wished. They must be shifted before they begin to flower, or the moisture may tend to non-setting; for, like the majority of fruits, the pollen must be dry to be effective. Plants of two successive sowings are quickly following on the heels of this lot, but for the present have colder treatment to get plenty of stamina into the growth. Long red and the yellow-fruited Prince of Wales Capsicums, together with the miniature red Chilli, we have sown in shallow pans and placed in heat, to be presently pricked off into pots and again returned to heat till ready to be potted singly, then frame treatment suits them well. Of course, their principal value is in their being an indispensable condiment in pickle, or, in fact, for pickling separately, but we generally reserve a few for growing on for ornamentation. They stand well in dark corners of rooms where more valuable plants quickly perish, and they look specially appropriate on the

sideboard or mantelpiece of a dining-room. The variety Prince of Wales is naturally of a bushy habit of growth, and is therefore the best of the three for decorative use in plant form, and though yellow-fruited it is quite as piquant as are the red; it is therefore doubly valuable in comparison with the others.

ORCHIDS.

W. H. GOWER.

ORCHIDS AT DOWNSIDE, LEATHER-HEAD.

A PEEP merely at Mr. Lee's collection of Orchids just now would be sufficient to convince the most sceptical that Orchids are not only free-flowering, but healthy and ornamental. If one were compelled to select ten kinds from this collection better than the rest the task would be a difficult one, for here are thousands of flowers in almost endless variety, both in the way of colour and shape; take, for instance, the

CATTLEYA HOUSE.—In this there has been a grand display from the beginning of the year till the present time, consisting of the choicest varieties of *C. Trianae*. What other flowers would last two months in perfection during the dreariest and coldest period of our winter season, and yet keep producing hundreds of flowers which may keep in perfection another month? This, however, will not be permitted, for they will soon be cut in order to prevent the plants becoming exhausted; by attention in this way the crop for next year will be secured. Of varieties of *C. Trianae*, a most variable species, we will merely on this occasion mention the best. *Leana*, therefore, stands first on the list; it has large bold flowers which often measure as much as 7 inches across; the sepals and petals in this variety are broad, and deep rosy lilac in colour flushed with purple; the lip, which is large, is spreading in front, and rich magenta flushed with lilac-rose, whilst its large throat is streaked with orange. *Osmanni* is another fine form of *Trianae*, totally distinct from the last. It has flowers nearly or quite as large, the sepals and petals of which are bright rose flushed with magenta, and the whole of the front of the lip is deep rich velvety magenta-crimson, the basal portion and throat being pale yellow. Other richly-coloured forms are also numerous, such as *Backhouseana*, *eboracensis*, *magnifica*, *Noimani*, *Emperor*, and *Archiduc*, not single-flowered, but plants producing dozens of blooms. There are likewise numerous kinds in the way of delicata in which the sepals and petals are white, with a more or less deeply tinted mauve lip with yellow throat. There are here, too, some grand examples of alba, a kind in which the whole of the flower is as white as snowdrift, with the exception of a slight stain of lemon in the throat. In addition to these there are numerous forms of that rich and warm-coloured species *C. Percivaliana* associated with the plants of *Trianae*; in one form in particular the flowers are very large and the lip well open; the sepals and petals are deep rich rose flushed with purple, and the lip intense deep purplish crimson flushed with orange. With this variety *C. amethystoglossa* contrasts strikingly, its waxy flowers being pale rose in colour, profusely spotted and dotted with rich purplish magenta. Various handsome forms of *C. speciosissima* are also now in perfection; their sepals and petals, which are pale flesh colour, are almost circular, and the lip is rich amethyst, the throat being variously marked with white and different shades of yellow.

THE *ODONTOGLOSSUMS* here are at present magnificent; many hundreds of racemes are just opening, and many more are making themselves

visible. Foremost amongst them is the unique hybrid called *Lecanum*, which some authorities rank as a variety of *odoratum*, from which, however, it appears to be abundantly distinct. It bears a many-flowered raceme, the individual blooms on which are between 3 inches and 4 inches across; the ground colour is bright canary-yellow, spotted and dotted with chestnut, and on the front of the lip is a conspicuous brownish crimson blotch. *Horsmani*, which is supposed to be a hybrid between *luteo-purpureum* and *Pescatorei*, is a bold-growing and handsome form, the sepals and petals of which are yellowish white blotched with deep brown and crimson. *Hebraicum* is another striking and beautiful variety, having a pale yellow ground, streaked and spotted in a singular manner with bright brown. *Edwardi* is a remarkable plant, different in colour from that of any other known member of the family; moreover, it emits a grateful perfume, resembling that of Violets; the plant, which is a vigorous grower, produces a many-flowered branching panicle from 3 feet to 4 feet in length; the blooms, which measure about an inch across, are violet-mauve in colour, the lip being stained with yellow at the base. Plants of *crispum* *Alexandra*, which are flowering in vast quantities, and exhibiting almost endless variety in size, shape, and markings, from pure white to purplish rose and heavily spotted, are all in lovely condition. *Pescatorei*, a well-known kind, ever chaste and beautiful, with pure white blooms just tinged at the base with violet-purple, may be found there, as may also *mulus*, a large-bloomed sort which bears some resemblance to *luteo-purpureum*; the blossoms, which are borne upon branching panicles, have a yellow ground colour, more or less deep, blotched and barred with cinnamon; the large, fiddle-shaped lip is pale yellow blotched conspicuously in the middle with brown, and a few smaller spots of the same colour occur near the rest, which is beset with bristles. *Erstedii* *majus* also is a truly beautiful variety, the flowers of which are treble the size of those of any *Dendrobium* we have hitherto seen; the flowers are spreading, pure waxy white, with a clear yellow stain at the base of the lip. This variety appears to enjoy a somewhat higher temperature than most of the *Odontoglossums*. The beautiful *Oroseum*, a name recently exchanged for the ugly and unpronounceable one of *cochlioda rosea*, is pushing up its numerous rosy crimson flowers freely, as is also *Roezli* and its white variety *alba*; these three just named have been relegated to the genus *Miltonia*; they require the warmth of a *Cattleya* house to keep them in health and induce them to flower. Other noted kinds were *Willekeanum*, *aspersum*, *Humeanum*, *Rossi majus*, *pulchellum majus*, *tripudians*, *gloriosum*, and *odoratum* in many varieties, all and at the same time beautiful.

AFRIDES, VANDAS, SACCOLABIUMS, and other distichous-leaved Orchids are likewise largely grown, here and amongst them many large plants of *Vanda tricolor*. *V. suavis*, too, with its china-white flowers and purplish crimson markings, loaded the air with an agreeable perfume; many of these Vandas, though standing and flowering in the comparatively cool and airy atmosphere of the *Cattleya* house, are grand specimens some 4 feet or 5 feet in height, and laden with fragrant blossoms. They do equally well in baskets as in pots, an assertion fully borne out by the annexed illustration. Amongst *Aerides*, *Lawrencei* is still in flower, and *A. Thibautianum*, perhaps better known as *A. Huttoni*, is just opening its rosy purple flowers a grand specimen of the white honey-scented *Saccolabium Harrisonianum* is bearing twelve trusses, and of greater length than any we remember to have previously

noted; the rare *S. gemmatum* and *S. bellinum*, though small, contribute their share to the display. They are, however, completely overshadowed by the grand racemes of *S. giganteum*. Other plants worthy of notice in this section are the rare *S. curvifolium luteum*, and the elegant *Angraecum citratum*, which is bearing dozens of spikes of delicate blossoms.

PHALANOPSIS are also magnificent, the chief varieties in bloom being *Schilleriana*, *Brymeriana*, *amabilis* and *Stuartiana*; the flowers of the last are very large and more richly spotted even than usual. The coldest house plants are the *Masdevallias*, which are extensively grown by Mr. Lee; those now in flower amongst them are *igneae*, *Harryana*, *amabilis*, and a very large form of *Shuttleworthi*. The blooms of *Chimara* are just

Vanda suavis.

opening, as are also those of *Backhousiana*, which resemble the preceding, but are larger and brighter; *Roezli*, which also belongs to the same group, has flowers of an intense blackish purple.

DENDROBIUMS are numerous and beautiful, the genus now in flower being the charmingly coloured noble *nobilis*, the flowers of which are deep crimson-purple, with an intensely black-purple blotch in the lip. Many fine examples of *Ainsworthi* may be seen here; this kind is, however, now surpassed by *splendissimum*, the flowers of which are very large and white suffused with rose; the lip, which is deep velvety purple, has just a suspicion of yellow in it near the base. Associated with these were grand examples of *D. Wardianum*, *crassinode*, *fimbriatum*, *Findleyanum*, and its variety *roseum*; also *luteolum*, with its primrose-coloured flowers, and a

curious kind called *Tollianum*, which appears to be a very deep-coloured form of *nobile*, in which the sepals and petals are marked in a manner similar to the lip.

CYPRIPIDIUMS are represented by good plants of *Schlimi* and the variety *albiflorum*, which still continues rare, and does not appear to be so easily managed as many others. *C. venustum*, with its peculiar blue-green marbled leaves, and in this instance brightly coloured flowers, was in great beauty, as was also *grande*, a gigantic member of its race with large bright, flesh-coloured flowers, belonging to the *Roezli* section. We also noticed some deeply spotted forms of *Boxalli*; also *vernixium*, a hybrid raised between *Argus* and *villosum*, in which the beauties of both parents are happily combined; the beautiful hybrid *calurum*, with rich crimson flowers, and *calophyllum*, a kind in which are combined the beauties of *barbatum* and *venustum*. This, with the brilliantly coloured, though somewhat small flowers of *barlatum* *Warneri*, includes the majority of the best Orchids.

ONCIDIUMS, though not numerous in this collection, include some richly spotted varieties of *sarcodes* and numerous examples of *cheiroporum*. The now much-neglected family of *Ependrums* is represented by some beautiful species, especially those of the *paniculate* section. Of these, the most noticeable were *xanthinum*, with large heads of orange-yellow flowers; *arachnoglossum*, with violet-crimson flowers; the lip of which has a yellow crest and is prettily fringed; *Endresi*, a diminutive plant with distichous leaves and small pure white flowers, the lip and column being blue. *Lycastes*, which are well represented, vary in colour from deep crimson to pure white. Amongst *Celogynes* we especially noticed *conferta*, a close, compact form with short spikes and numerous flowers, somewhat in the way of those of *ocellata*. Of *flaccida* there are large specimens with numerous long, drooping racemes of bloom; *cristata*, too, with its numerous snowy flowers, may be seen here in abundance; also fine examples of the variety *alba*, which is perhaps the purest example of a white Orchid we have, there being not a speck or tinge of colour to mar its purity.

Amongst miscellaneous Orchids in flower are *Ada aurantiaca*, with drooping racemes of orange-red flowers; *Zygopetalum crinitum*, with large blue-veined lip; the white and yellow-flowered *Pilumna nobilis*; *Calanthe pleiochroma*, belonging to the *Masna* section with evergreen leaves. In this kind the scape is erect and the flowers lilac, with a crimson crest. Associated with these were the old and now seldom seen *Warrea tricolor*, *Colax jugosus*, with flowers white outside, but prettily barred within with blue; *Laelia harpophylla* and *flammea*, the former with orange-vermilion flowers, the latter with brilliant cinnamon ones; and *Phajus tuberosus*, a recent introduction from Madagascar. This last has hitherto proved to be rather intractable; it is, however, blooming freely here; the scape is erect and the flowers large; the sepals and petals are white, and the lip yellow, the large side lobes being profusely spotted with brownish crimson, while the front lobe is white, spotted with rosy purple; crests yellow. With the new *Maxillaria Sandersi* we close the list. This last is a remarkable plant. It grows as strongly as *M. grandiflora*, and has large flowers, with pointed sepals and petals the shape of those of an *Acanthophippium*, and furnished with the markings of *Stanhopea tigrina*. In all, Mr. Lee must have about 200 species and varieties of Orchids now in flower.

Cymbidium Lowianum.—At p. 199 Mr. Osborne inquires about the number of flowers on

a spike of this species. We have a plant of it now on which the flowers are opening. It has four spikes, on which are 140 flowers; the greatest number on one spike is 43. Previous to this season the greatest number of flowers I ever knew to be produced on one spike was 33. The plant in question was a small one, in a 5 inch pot, in May, 1885. It is now in a 13 inch pot, and will require to be repotted again when the flower-spikes are cut off. We grow this species in loam, leaf mould, and manure in preference to peat soil.—J. DOUGLAS.

Odontoglossum pardinum.—This is a bold, robust-growing plant, nearly allied to *O. Lindeni*. Its flowers are produced in panicles, which are branched and many-flowered, and in some varieties reach nearly 3 feet in length, but a form of it which we recently saw in the Selborne collection at Streatham bears a much-branched panicle not more than 2 feet high, densely laden with very fragrant flowers, the sepals and petals of which are much undulated and golden yellow, profusely spotted with reddish brown; the lip, which is somewhat fiddle-shaped, tapers to a sharp point and has a broad blotch of chestnut-brown at the base, and a few spots of the same colour in front.

Calanthe vestita alba.—From Mr. Laing, of Forest Hill, come some flowers of a *Calanthe*, which he thinks is a white form of *C. Veitchi*. It is not, however, a form of *Veitchi*, inasmuch as its lip is deeply cleft into four deep blunt lobes of the same shape as those in the typical *C. vestita*; whilst that of *C. Veitchi* is only slightly notched in front, resembling in shape somewhat the lip of *Limatodes rosea*. The flowers of this variety are very beautiful, being snow-white without the slightest tinge of colour—a circumstance which should cause it to be sought after wherever white flowers are in demand. This variety, we believe, appeared amongst a consignment of *Calanthes* from Cochin China belonging to the Regnier section, both it and the variety *Stevensi* having pseudo-bulbs resembling more those of *C. Veitchi* or *Limatodes rosea* than the typical *vestita*, and all of them come into flower after the ordinary *C. vestita* has done blooming, a circumstance which makes them most desirable.—G.

SHORT NOTES.—ORCHIDS.

Cheap Orchids (*R. Harvey*).—Consult the lists of the leading growers and importers. At the London sales, too, some kinds are sold at very low prices.

Cœlogyne flaccida.—This is now in flower at Syon House, where it is grown in a basket suspended close to the glass. It is at the present time bearing fifteen of its long, pendulous racemes of flowers, which are very effective.

Dendrobium splendidissimum.—This hybrid raised by Mr. Seiden is a cross between *D. nobile* and *heterocarpum*, and is now in flower in the Messrs. Veitch's nursery at Chelsea. The flowers are very large, the petals and sepals white tinged with pink, the lip also slightly tinged, and with a dark purple throat. It also is in flower in Mr. Lee's collection at Downside.

Phalenopsis at Park Hill, Streatham.—The display of Moth Orchids at this place is now very grand; many of the plants still in full flower have been so for nearly two months. Amongst the principal kinds are *Schilleriana* in variety, with large branching panicles bearing in some cases fifty flowers, whilst some of the forms of *anabilis* have by far the largest flowers which we have hitherto seen.—G.

Masdevallia ignea.—Numerous varieties of this brilliant and tree-blooming species are now in flower in various gardens round London, and one of the finest is that named *Massangeana*, a variety in which the flowers are much larger than in the type. Their ground colour is bright orange-velvet, the prominent veins of the connate sepals being rosy purple. The bright colours of the different varieties of this plant contrast strikingly with the pure white flowers of the *Alexandra Odontoglossum*.

Dendrobium crassinode.—This is characterised by its thickened and knotted joints, from which its name is derived. Many hundreds of plants of it are now pushing up their flowers in Mr. Low's nursery. The blooms are produced on the previous year's growth, which loses its leaves during the resting season. The sepals and petals are waxy-white, the tips being more or less broadly suffused with purplish magenta, lip of the same colour, blotched at the base with a orange. A form with pure white flowers has bloomed in Sir Trevor Lawrence's collection at Dorking.—G.

Lælia anceps Protheroianum.—Large quantities of this Orchid have been introduced during the past few years, and amongst their flowers there has been great variety, some being pure white, whilst others have been darker than the type, but all, nevertheless, beautiful. The variety called *coccinea* has hitherto been the richest in colour, but

Messrs. Horsman, of Colchester, have one even finer than it. In this the sepals and petals are deep reddish crimson, and the lip intense deep crimson, with some yellow line on the sides of the throat.

Mr. Harvey's collection.—This is to be sold by the Liverpool Horticultural Company. It is a choice collection, made so by continual weeding by Mr. E. Harvey, of Aigburth, and contains healthy specimens of such varieties as the old autumn-flowering *Cattleya labiata*, *C. Skinneri alba*, *C. Wageneriana* and *Reineckiana*, *C. calumnata*, *Lælia elegans*, *Turneri alba*, *prasiata*, and *pieta*; *L. anceps* Dawsoni, *Schroederiana alba*, *Williamsi*, *Hilli*, *flamula*, &c.; *Vanda Sandeiana*, *Dendrobium Falconeri*, *giganteum*, and *Harveyanum* (sp. n.w.).

Phalænopsis.—In Mr. W. Philbrick's garden at Oldfield, Bickley, various species and varieties of these plants are now laden with handsome flowering spikes, conspicuous amongst them being two very fine varieties of *P. Stuartiana*, both being densely and delicately spotted at the base of the sepals. *P. casta* is represented by a very fine variety, the flowers measuring upwards of 3 inches across. A good variety of *P. Schilleriana* is bearing eighteen flowers on the spike. The house is of small size and span-roofed. All the plants are suspended in baskets from the roof; and on the borders underneath are planted *Fittonias* and other fine-foliaged plants of free and spreading growth.—J. D.

Odontoglossum Alexandræ.—The first figure of this plant was given in Mr. Bateman's "Monograph of the Genus *Odontoglossum*," a work unhappily still incomplete. It represents the flowers as being pure white, with the exception of a blotch or two in front of the yellow crest of the lip. We recently observed a plant of this type, but infinitely superior to that in question, blooming with Mr. Jacomb at Stamford Hill. Its flowers are arranged distichously on the raceme, and individually they are large and full, the petals being beautifully fringed. This variety stands out conspicuously from dozens of other good forms, quite eclipsing them by its chaste beauty and the purity of its blossoms.

Cœlogyne culture.—The remarks made on this subject in THE GARDEN (p. 191) are not quite in accordance with my experience. We do not consider this a cool-house Orchid, and I should certainly like to know where it is to be seen "grown to perfection in a cool, moist greenhouse." I visit most of the principal collections of Orchids near London in the course of the season, and cannot recollect one place in which it is grown in a cool house. Mr. Pollett has been wonderfully successful with *C. cristata alba* at Bickley, but all the year round it is grown in the warmest *Cattleya* house. Some remarkable specimens may likewise be seen in Mr. Philbrick's garden, which is also at Bickley; the variety said to be *maxima* had thirty spikes, and each spike was furnished with from six to seven blooms, but the plants there are not in a cool house. As to growing Orchids in what is generally understood to be a cool greenhouse, I would go a long way to see such a feat successfully accomplished. I was told that I could see it in Dr. Duke's garden at Lewisham. I went there, and found the case reversed, viz., greenhouse plants growing in an Orchid house—a very different thing. Dr. Duke repudiated the idea of growing Orchids in a greenhouse. What is the experience of cultivators generally in regard to growing such Orchids as *C. cristata* in a cool greenhouse? I may say that we had three plants potted in the new material called *Trepho* last year, and they have done remarkably well.—J. DOUGLAS.

Thrixspermum unguiculatum.—This curious Burmese Orchid we recently saw in the nursery at Holloway. Its foliage reminds one of that of a *Phalænopsis* of the *Ludemannii* section; indeed, it has received the garden name of *Phalænopsis Luckeriana*. Its stem, which is short, bears oblong, strap-shaped, two-ranked leaves, some 9 inches long, bluntly notched at the ends, thick and fleshy, and deep green.

The flower-scape, which is about as long as the leaves, produces towards the top numerous spreading, fleshy, ivory-white flowers; the front lobe of the lip is dotted with crimson, and the side lobes are striped with the same colour. This plant should be grown upon a block of wood or in a shallow pan. The raceme being pendulous, the flowers are seen to the best advantage when suspended from the roof.

CHRYSANTHEMUMS.

E. MOLYNEUX.

WHERE there are no glass structures Chrysanthemums may be grown well on spare walls, and even where there are glass houses such spaces may be utilised by planting against them the old plants that bloomed indoors the previous season. The main point is to employ suitable varieties. Pompons and single varieties are specially suited for such purposes; they flower profusely, and owing to the thinness of their petals they do not suffer nearly so much from rain as do heavier incurved varieties. Reflexed kinds answer capitally for wall culture, especially medium-sized sorts belonging to the Japanese section and a few of the incurved kinds. A southern aspect suits them best, and if there is a wide coping on the wall so much the better, as that prevents the blooms from becoming soaked with wet. If the wall is 7 feet high, so much the better, as larger flowers and more in quantity can be produced than on a wall not so high; still on a wall of less height blooms may be had by training the shoots in a different manner. Let us assume that the wall is 7 feet high, and that large blooms and a quantity of smaller ones are desired. Now is a good time, or early in April if more convenient to plant out the plants. As before stated, old plants are better suited for this purpose than young ones raised from cuttings made of the current year's wood, owing to the extra number of shoots produced at the base, the result being more branches to begin with. Remove part of the old soil from the roots, and plant close to the wall and 3 feet apart; add some manure, increasing or diminishing the supply according to the character of the soil. Between every two large-flowered varieties plant alternately one Pompon and one single variety. The Pompons and single kinds will cover the bottom part of the wall, and thus the space above them will be devoted to the large-flowered sections. Tread the soil firmly about the roots, and when growth has fairly started water freely. Many shoots will spring from the base of the plants if the latter were of good size the previous year. In the case of each of the large-flowering varieties select four of the strongest growths, removing all others, and in that of the Pompons and singles retain six. When the growths are long enough spread them out thinly and fasten them to the wall, continually doing so as growth proceeds. Neglect of this spoils the effect both of flowers and foliage, as the branches are easily broken by wind. Do not top the branches; when the first natural break takes place select two of the strongest growths on each stem, or more if space permits, and remove the remainder.

Where size of flower is a speciality, allow three stems on each plant to produce a single bud, removing all other side growths, but in the case of branches upon the same plant intended to produce a quantity of flowers remove the flower-bud formed in August, when another set of growths will start from the point from which the flower was removed. By growing both single blooms and a number of others upon the same plant the wall is not rendered thin in appearance when the flowers expand, as they otherwise would do were one plant devoted to a few blooms, one on each stem, for instance. The foliage of both Pompons and single varieties being much smaller than that of the large growing kinds more shoots can be retained on the first growths; from 3 inches to 4 inches is a suitable distance at which to train these shoots apart. In the case of

kinds of this character allow all flower-buds to develop in order that blooms may be found on the whole length of the shoots. Encourage free growth by thoroughly syringing the plants after a hot day; this greatly assists in keeping the foliage clean and in rendering the wall cool during the night. Where the wall is low compared with that previously named a different method of training must be practised; tall-growing kinds should be dispensed with, and where large blooms are the object, which can only be had by allowing the branches to grow away naturally, so to speak, these must be laid in to the wall obliquely, and so that they cross one another. Where, however, quantity of blooms is the primary object, top the plants when about 6 inches high, and continue doing so till the end of June, laying in the branches as space permits. As soon as growth is fairly established and the roots running freely give liquid manure in a weak state; the times at which it should be applied must be guided by the weather, be it wet or dry. If the latter, give copious supplies once a week, increasing the strength when the flower-buds are formed. Treated in this manner, in favourable seasons blooms can be had from such walls during eight or ten weeks, a consideration late in autumn. Frost following on the heels of rain is the worst enemy with which Chrysanthemums have to contend during the blooming period; the flowers being heavily charged with moisture are much less able to resist the effects of the frost than when the flowers are dry.

Where choice can be had of varieties the following will be found suitable, but where such is not the case avoid all kinds the blooms of which are heavy in character, holding as they do too much water after rains and heavy dews. Reflexed: Golden Christine, Pink Christine, Mrs. Forsyth, King of Crimson, Phidias, Progne, and Chevalier Damage. Incurved: Mrs. G. Rundle, George Glenn, Mrs. Dixon, Refulgence, Pink Venus, Othello, Jardin des Plantes, and Lady Slade. Japanese: Dr. Macary, Bouquet Fait, Peter the Great, Elaine, Tendresse, Mons. Mou-sillac, Margot, Mademoiselle Lacroix, Lady Selborne, Harlequin, George Gordon, L'Incomparable, The Daimio, Triomphe du Nord, La Nympe, and Madame de Sevin. Pompons: White Trevenna, Snowdrop, Golden Circle, Nelly Rainford, Rosinante, St. Michael, Lizzie Holmes, and Prince of Orange. Single varieties: Oscar Wilde, Patience, Mrs. Langtry, Mary Anderson, Nelly, Oriflamme. These are varieties all suitable for the purpose. Many more might be named, but these will make a good display.

Plants grown for producing large blooms for exhibition will now, in most cases, be in 3 inch pots; some in 4½-inch pots, while others will be only as yet in the cutting pots. The latest should, however, now be ready to receive a first shift; where the plants have had the benefit of a shelf close to the glass in a cool house they will be dwarf and stocky. The strongest, and even all except the very smallest, which have taken to the new soil after the first potting should be removed to a cold frame, and set on a good thickness of coal ashes, which form the best of all foundations on which the plants can stand, as it prevents the ingress of worms which often derange both soil and roots, and thus do injury, as the soil in which Chrysanthemums are grown should be firm and solid. The soil used in potting in this case should be the same as that recommended last week (p. 212), and in mixing it care should be taken to eject any worms seen therein. Place the plants close to the glass; keep them rather close for the first few days after removal, as the winds are often cold and cutting, which, in some instances, causes the foliage to turn yellow. This causes a check which should be avoided, if possible; gradually tilt the lights a little during the daytime, always on the side opposite that from which the wind is blowing; increase the supply of air gradually as the days lengthen and the sun gains strength, until the lights in very fine days can be daily removed altogether for a few hours.

Cover up the frames at night to protect the plants from frost, as if the points of the shoots at this stage are injured, a check will be the result. Do not stop them by taking out the point of each, but allow them to grow in a natural manner, and to each stem put a small neat stake by way of support.

CHRYSANTHEMUM PRIZE SCHEDULES.

THESE should be concise and clear as regards what may be required in order to prevent disappointment. No prizes induce so much competition, or bring so many good specimens together as do challenge vases, which prove a stimulus both to exhibitors and visitors. A good prize in money and a challenge vase encourage the best growers to enter the lists, and the result is a good show. It is, however, a mistake to offer such prizes for very large numbers of varieties, as say, for instance, forty-eight distinct kinds. Such a number prohibits many from competing, as it is most difficult for even the largest growers to cut so many blooms at one time; consequently inferior flowers have to be substituted to make up the number, thus deteriorating an otherwise good stand. What is better calculated to make a good show, and ensure brisker competition, is the class for forty-eight blooms in thirty-six varieties, half to be Japanese and the remainder incurved—not more than two of one sort. There is no comparison between the two classes as to the ease with which they can be filled. More uniform stands can also be obtained by allowing duplicate blooms, and the general public are better satisfied. The classes for Anemone-flowered varieties, too, need consideration; owing to the advent of what are now termed Anemone-Japanese sorts, the older varieties of which, Gluck and Acquisition, are fair representatives, are fast being elbowed out of the shows by their more showy and attractive rivals. To remedy this, separate classes should be made for each. Prizes ought to be also offered for single varieties, both in a cut state and in the shape of plants grown in a somewhat natural style, commonly called "bush" plants. The various colours and forms of these single sorts, combined with the freedom with which they are produced, specially recommend them for more general cultivation than they at present receive. When in a cut state, prizes should be offered for so many bunches of them, number and variety being according to circumstances twelve bunches and, say, six varieties, would be found to meet the case, at least at first. Some societies do not encourage the reflexed section sufficiently. Varieties belonging to this section are, however, particularly well adapted to exhibition, and they are more easily grown than the general run of the incurved sorts; very free, in every respect is the Christine family, more particularly the white one. Dr. Sharpe is specially to be recommended, its lovely magenta coloured blossoms being very rich when seen in a mass. Take, again, Cullingfordi, a variety which has had a good deal of buffeting about, first in one class and then in another. Without doubt, however, it belongs to the reflexed class; were it placed in any other it would soon be neglected, and that would be matter for regret, as the loss of its brilliant colour would be a misfortune. The judges' names, I may add, ought to be published in show schedules, as being more satisfactory to intending competitors. E. M.

Black Vine weevil (*B. Cash*).—The grubs attacking the roots of your Ferns are the grubs of that very destructive insect, the black Vine weevil. They cannot be destroyed without taking the Ferns out of their pots. They also attack the roots of Cyclamens, Begonias, Primulas, &c. The best way of getting rid of this insect is to destroy the parent beetles, which are nearly black and dull in colour. They are about half an inch in length, and somewhat sluggish in their movements; they generally remain hidden during the day, coming out after dark to feed. They feed on the foliage of Vines and many other plants, gnawing great notches in them. If you can find the plants on which they are feeding, place them on a

white sheet, and when quite dark suddenly throw a bright light on them; this generally startles the weevils, and they fall, feigning to be dead. A sharp shake to the plant helps matters; if they do not fall, carefully examine the plants.—G. S. S.

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 8.

THE meeting of the fruit and floral committees, which was held in the conservatory, was, in spite of the foggy weather we have just had, rendered extremely bright by the fine collection of Camellias from Messrs. Wm. Paul and Son, the Orchids from Mr. Little, and the Narcissi and other welcome spring flowers from Messrs. Ware, Collins and Gabriel, and Barr and Son.

The following first-class certificates were awarded, viz., to Rhododendron La Belle, a cross between R. ciliatum and R. Forsterianum, bearing large, pure white, cup-shaped flowers. Exhibited by Messrs. Veitch. The same firm were also awarded a first-class certificate for Anaryllis Nestor, a variety bearing flowers of fine form of a beautiful scarlet, the petals being tipped with greenish white. On one of the flower-stalks there were four fully expanded flowers. Rose The Bride, a beautiful sulphur yellow Tea Rose. Shown by Mr. J. Gilmour, jun., Sheffield.

Sir Trevor Lawrence, Bart., M.P., Burford Lodge, Dorking, exhibited a plant of Anthurium carneum, bearing three very large spathes, each measuring 6 inches by 7 inches. The flowers are pale scarlet on very long footstalks. He also exhibited a very fine form of Phaius tuberculatus named superbus. This is undoubtedly the finest variety of this we have yet seen. A cultural commendation was deservedly awarded. The Hon. and Rev. J. T. Boscawen, Tregothnan, Probus, Cornwall, exhibited a finely flowered plant of Dendrobium nobile. Mr. De B. Crawshaw, Rosefield, Sevenoaks, sent cut flowers of varieties of Odontoglossums and other Orchids, noticeable being Odontoglossum Wilckeianum albens, O. Rossi majus rubescens, Masdevallia Shuttleworthii xanthocorys. Mr. Vanner, Bickley, sent a plant of Cattleya Trianae Vanneriana. Mr. Courtauld, Braintree, Essex, sent a superb variety of Cattleya Trianae var. Courtauldi. The specimen was superbly flowered, and the flower throughout was of a beautiful dark shade—certainly a very fine variety. A cultural commendation was awarded. Mr. J. Pitt, The Gardens, Cassiobury Park, Herts, sent a beautifully flowered example of Dendrobium nobile grown in a basket. The plant was one mass of bloom, and well deserved the cultural commendation awarded. Mr. B. D. Knox, Caversham, Reading, sent varieties of Cattleya Trianae, Laelia anceps, &c. Mr. Little, The Barons, Twickenham, sent a collection of varieties of Lycaste Skinneri. These varied very much in their markings and size of flowers. Noticeable was a beautiful dark variety carrying twelve of its beautiful flowers. Mr. Little also staged a finely flowered example of Cattleya Trianae and several forms of Odontoglossums. A silver Banksian medal was deservedly awarded.

Messrs. William Paul and Son, Waltham Cross, N., exhibited a superbly flowered lot of Camellias, as also twelve boxes of cut blooms. The pot specimens were thickly covered with fully expanded blooms, set off to the greatest advantage by the healthy foliage with which they were clothed. Conspicuous were the two American varieties, C. M. Hovey and C. H. Hovey; Montrioni vera, white incurved petals, the flower in some cases tinged with pink at the base of the petals; Cup of Beauty, beautifully pink shaded; Mathottiana, the old and well-known alba plena; and L'Avenir, a variety with large, full flowers of a beautiful pink colour. The cut blooms were also large and in fine condition. They well deserved the silver-gilt Banksian medal awarded.

Mr. T. S. Ware, Tottenham, exhibited a magnificent group of Daffodils, both cut and growing in pots, interspersed with such spring favourites as Chionodoxa Luciliae, Chionodoxa sardensis, Lachenalia, Freesia, Anemone fulgens, &c. A silver Banksian medal was awarded.

Messrs. Barr and Son, King Street, Covent Garden, also staged a group of Narcissi, fringed with the showy *Anemone fulgens*. A bronze Banksian medal was awarded.

Messrs. Collins Brothers and Gabriel exhibited a group of Narcissi, brightened up with here and there patches of *Chionodoxa Lucilie* and *Chionodoxa sardensis*, *Anemone fulgens*, *Freesias*, *Iris reticulata*, &c. In this group there was also shown a variety of *Primula obovata* under the name major, and as shown the individual flowers were certainly larger than the type. A silver Banksian medal was awarded.

Messrs. Paul and Son, The Old Nurseries, Chesham, exhibited a small group of hardy spring flowers, consisting of *Cyclamen Atkinsi* in variety, *Galanthus Shaylocki*, *Corbularia monophylla alba*, and *Rosa indica*. From the same firm were also exhibited plants of *Prunus Pissardi*, to show its fitness for forcing. As seen, it certainly merits attention for this purpose, wreathed, as it was, with its beautiful pink flowers, backed by the metallic foliage peculiar to this variety. They also exhibited the new *Saxifraga Frederici Augusti*, a yellow-flowered form, which somewhat resembles a variety named *Sancta*. The flowers of the former are produced in greater abundance and on longer footstalks. From the same firm was also sent *Ilex scurtica picta*.

Messrs. Pope and Sons, King's Norton Nurseries, Birmingham, sent four new varieties of *Primula sinensis*. The flowers were very large and of good colour, but somewhat rough. Messrs. Pope and Sons, Twickenham, exhibited some good forms of *Odontoglossum crispum*, as also a very fine group of *Cyclamens*. The flowers, ranging from pure white to intense purple, were large, more especially in the case of the white varieties, and a bronze Banksian medal was awarded. Mr. Ross, gardener to Sir George Macleay, Pendell Court, Bletchingley, exhibited flowering sprays of *Acacia verticillata*, the earliest and the most graceful of this class of plants, as also cut sprays of *Thunbergia Harrii*, with pale blue flowers and distinct yellow eye. Mr. W. Gordon, Twickenham, sent a Japanese *Camellia*, named *Lady Clancarty*, bearing pure white flowers. Mr. J. James, Woodside, Farnham Royal, sent blooms of his superb strain of *Cinerarias*. Mr. F. Moore, Botanic Gardens, Glasnevin, sent a collection of *Lachenalias*, consisting of *Lachenalia aurea*, *L. Nelsoni*, *L. luteola*, *L. orchoides*, the flowers large, greenish; *L. pallida*, flowers small, greenish white, the points of the flowers tipped with violet; also *Catasetum discolor*. Mr. Barron sent from the Society's Gardens, Chiswick, a pan containing grandly flowered examples of *Saxifraga Bursariana*. Messrs. James Veitch and Sons also exhibited *Amaryllis Iona*, a variety with whitish petals striped with red, and *Lomaria gibba platypetala*, with broader fronds than the type. Messrs. Green and Nephew exhibited their Munstead flower-glasses. These may be had in all sizes and shades of colour, and are very useful for arranging cut flowers. Mr. Benjamin Locker, Kingston-on-Thames, exhibited a new flower-pot in which a portion of the base is cut off, thus forming a saucer with a hole in the centre. This portion is inverted and placed inside the pot, thus affording complete drainage, and doing away with the use of crocks.

Fruit committee.—Messrs. Thomas Rivers and Son, Sawbridgeworth, exhibited a few varieties of Apples, conspicuous being *Archiduc Antoine*, a round yellow-skinned variety; *Buckingham*, oblong green-streaked, very handsome; *Wagner*, *Allen's Everlasting*, a very late variety; *Baxter's Pearmain*, a beautiful late Apple; *Lord Burghley*, *Bailey's Sweet*, and *Mannington's Pearmain*. These were all in good condition.

Mr. S. Ford, The Gardens, Leonardlee, Horsham, sent nine dishes of Apples, consisting of *Blenheim Orange*, *Hoary Morning*, of a beautiful colour; *Cockle Pippin*, *Bosom Apple of Sussex*, *Flower of Kent*, *Golden Russet*, *Barcelona Pearmain*. These had all been kept well and their colour was very marked. A bronze Banksian medal was awarded.

Mr. W. Roupell, Harvey Lodge, Roupell Park, sent some very fine samples of the *McLennan Apple*. They had been grown at Erixton Hill, and were in fine condition.

Messrs. Saltmarsh and Son, Chelmsford, sent an Apple named *Lord of the Manor*, a large yellow-fruited, conical-shaped variety with large open eye. The committee requested that it be again submitted next season.

Mr. Roberts, Charleville Forest, sent fruit of the white *Gros Colmar*, which were quite decayed.

Messrs. Spear and Jackson, 22, Queen Street, Cannon Street, sent a collection of their tools, consisting of spades, shovels, hoes, &c.

HARDY FRUIT SHOW AT CHESTER.

AN exhibition of hardy fruits (Apples and Pears) and a fruit conference were held the other day at Chester, with a view to stimulate both the production and consumption of fruit. A considerable number of local fruit growers, as well as many from a distance, favoured the occasion by sending some very fine collections of Apples and Pears—chiefly the former.

Amongst Apples were some grand specimens of—

- | | |
|------------------------|--------------------------|
| Alfriston | Herefordshire Pearmain |
| Golden Spire | Lord Derby |
| Winter Hawthorneden | Tom Putt |
| Blenheim Pippin | Hanwell Souring |

| Chamaent | Vicar of Winkfield |
| Bergamot Esp ren | Bezi Mai |
| Ne Plus Meuris | |

Mr. Baillie, in the course of an address on fruit growing, remarked that in the abstract of agricultural returns published by the Government in 1883 he found that 190,000 acres of land were returned under the head of orchards. At first that struck one as a wide area, but when he stated that in England alone the same return gave 68,000 acres as devoted to the cultivation of Hops, it would be found that Hop cultivation actually took up more than a third of the area given to British fruit growing. The total area of Great Britain was 56,786,199 acres; therefore only one acre in 300 was devoted to the cultivation of fruit. The population was 35,000,000, and it would be found that if the land was to be distributed amongst them, that each person would be the happy possessor, or rather the unhappy possessor, of about 20 yards of land from whence to obtain his fruit supply. Another feature was, that we were paying £7,000,000 annually for the importation of hardy fruits, or equal to 4s. per head per annum of the population for foreign fruits. A feature that he thought ought to be remembered was that fruit of some kind or other could be grown almost anywhere and everywhere. But though in Cheshire they had not the warm sunshine of Kent and Hereford, fruit growers ought not to be discouraged, for though, of course, a great deal depended on the climate, much more might be done by cultivation. He contended that in our own immediate district we had but too frequently the typical farmers' orchard; the too generally neglected orchard, with trees which were

venerable specimens of antiquity, covered with Lichen and other parasites, constituting them the happy hunting grounds of the cryptogamic botanist, but with no assurance of fruit crops.

With regard to storage, he noticed that in one of the collections shown there were some beautiful specimens of fruit said to have been stored in "hoggs," in the same manner as Potatoes; but whether that method could be carried out to advantage was open to trial. So, too, there was another lot said to have been gathered in the autumn of 1885. They were not particularly brilliant specimens, but being gathered so long ago it was not to be wondered at. Yet if Apples could be kept from 1885 till that time the question of fruit preservation was open to be still further considered. A great deal had been said as to whether it was really wise to go on planting fruit trees, but it seemed to him that as long as we went on paying millions of pounds annually for foreign grown fruit which might just as well be grown at home, the question as to whether or not fruit-growing would pay ought not to be asked. Then came the question of what tenants could do without long leases. The landlords should see to the utility and value of their property by planting orchards themselves on their farms.

Mr. Walker offered a few remarks on the growing of Pears and Apples on the northern coast of Wales. The principal conditions necessary for good crops of Pears and Apples, he said, were high temperature and moderate rainfall in July or August of the previous year, so that the wood might ripen, and an absence of severe frost during the blooming season. A rainfall of 2 inches, more or less according to the nature of the soil, was requisite in May when the fruit was setting, and complete rest or cessation of root action during the winter. If he were again to plant an orchard he would select a sunny slope, cut it down into terraces with low, dry, stone walls, and have his Pears and Apples trained on wire espaliers, 5 feet or 6 feet high, placed close to the walls. In his own garden, Apples on espaliers never fail to give a crop of some kind. It was well to take precautions against frost in spring, and he advised the planting of Pear trees on the higher slopes, which escaped the full severity of the frost, while the trees in the bottom of the valley were nearly totally blighted by frost. For Pears and Plums it was necessary to have the preceding July hot and dry, and for Apples the first three weeks in August hot and dry, while for all three considerable rainfall in May was necessary. That winter rest was essential could be abundantly proved by the fact that the countries producing the finest and most plentiful crops of Apples and Pears (North America, for instance) had colder winters than Britain. The best plan of combating this climatic defect on our part was root-pruning in November. Regarding the varieties of fruit best suited to the locality, he made it a rule not to grow dessert Apples that will not keep till February, when the best Pears are done, or attempt to grow any very late varieties of Pears. If the trees were watered in a dry May, they would never be without a crop of Apples. Unfortunately, the same could not be said of Pears, which were always capricious, although summer pinching and root-pruning might improve their chances greatly. In conclusion, Mr. Walker showed the meeting how 100 yards of espaliers could be erected for £1 15s. 1d., which would secure 600 yards of Apple cordon that would produce a great quantity of Apples.

Names of plants.—*G. T. Chichester*.—1, *Adiantum d. labrifforme*; 2, *A. Wilsoni*; 3, *Doryopteris palmata*.—*Sparg.*—1, *Cibotium Baronetz*; 2, *Fadyenia prolifer*; 3, *Cyrtotium carotidatum*; 4, *Vittoria lineata*; 5, *Platyloina atropurpurea*.—*W. B. WOODS & FORESTS.

PINUS MONTICOLA.

MORE perhaps as an ornamental tree than a valuable timber-producer is the above Pine known to us; yet in this latter respect it is certainly far from valueless, as the several fine samples of its timber exhibited at the late Colonial Exhibition, as well as the various uses to which it is applied, clearly pointed out. That such a beautiful and free-growing tree has now, after a fair and impartial trial, been found to be well suited for planting in our British woodlands is a matter of the greatest importance, for certainly few members of the Pine family combine the useful with the ornamental in so high a degree as the subject of our present paper. With very satisfactory results have we planted *Pinus monticola* in a variety of soils and situations, from the cold, rocky grounds near the base of the Pentland Hills to the warm, maritime situations of Northern England, and the flat, luxuriant plains of mid-Ireland, and in all these places it has done well, and amply repaid us for the small amount of care and attention required to be expended on its culture and general management. Not only in the above-named districts, however, has this Pine been found to be perfectly hardy, for in looking up Mr. Palmer's table in the "Pinetum Britannicum," we find only two instances of trees being killed by the frost during the severe winter of 1860 out of thirty-seven reported on, and one of these was otherwise ailing.

Pinus monticola is a handsome tree, about midway in appearance between *P. Cembra* and *P. Strobus*: indeed by some authorities it is ranked as but a variety of the latter. The whole contour of a fair-sized specimen may be said to be almost strictly pyramidal, not so much, however, as in *P. Cembra*, with an abundance of rather short branches, these being well clothed with dark, rich green foliage. The leaves are arranged in fives, are about 3 inches long, rigid, keeled, and slightly serrated on the margin.

When young the cones are of a pale green colour, but when fully matured they become a beautiful light foxy brown, and add considerably to the ornamental appearance of the tree, the contrast between the deep pleasant green of the foliage and orange-fawn of the cones being both striking and pretty. They resemble those of *P. Strobus* in a marked degree, being about half a foot in length, an inch in diameter, and cylindrical in shape. The male cones are in clusters around the stalk, about half an inch long, and with the scales of the same bright colour as the female cones. A peculiarity of the bark of fair-sized trees is that, like *P. ponderosa*, it splits into square plates, but for all this it never seems ragged and untidy, and being of a pleasing ash-brown or ashen grey has a peculiarly rich and desirable appearance when observed in the woodland. Many fine specimens of *Pinus monticola* are to be found in various parts of the country, notably at Riccarton, in Midlothian, Penicuik, in the same county, as well as in Perthshire, and throughout England generally. It flourishes best in a dampish, loamy soil, although we have known it to do well amongst shingly rock, and where but a small quantity of very inferior loam was present, and in this latter to put on a healthy tone that was not even surpassed by trees growing in what would be considered to be far more congenial situations. Sheltered positions are by no means necessary in the cultivation of this tree, for we have found it doing well and increasing rapidly in stem-bulk on high-lying grounds, and where partially exposed to occasional storms that told badly on certain other Pines that were considered to be far more hardy than the one in question. Where the soil is of poor quality we have found it highly beneficial in the cultivation of this tree to substitute a couple of hand-cartloads of good well decomposed leaf-mould for that in the pit where it is to be planted, although, as before stated, it is by no means fastidious when placed amongst

rocky debris, provided that constant dampness is always present, few Pines disliking alternate changes from damp to dryness more than this. Ample room should likewise be provided for it, the branches losing much of their fresh green appearance and well-furnished look when infringed upon by those of adjoining trees and shrubs. *Pinus monticola* is local in its distribution, being almost confined to high, rocky situations along the banks of the Columbia River, and one or two kindred places almost inaccessible.

The timber, of which a plank 18 feet long, 46 inches wide, and 3 inches thick was exhibited at the late Colonial Exhibition in the Canadian court, is well packed and firm, not of too deep a colour, but from what we could see of it and from a little experiment we were allowed to make, it should be well adapted for any purpose where strength and lasting qualities were of first importance. We were told that the timber is highly valued in its native country, but as the tree is scarce and grows in almost inaccessible situations, the chances of converting its wood are few indeed. As young plants of this Pine are now offered by our nursery firms at a very moderate cost, we would strongly advise all those who have planting operations on hand to give it a trial, and should these succeed in a satisfactory manner, additions can be made, for certainly experiments carried out on various estates from thirty to fully forty years ago warrant us in recommending *P. monticola* as a tree that even for ornamental appearance is well worthy the attention of planters.

A. D. WEBSTER.

Penrhyn Castle, North Wales.

CHOICE HOLLIES.

I WAS pleased to see a short, but encouraging notice of *Ilex dipyrrena* in THE GARDEN (p. 173), and hope many who have not hitherto planted it will be induced to add one or more plants of it to their collections. I can corroborate the statement that it is perfectly hardy, an established plant of it having withstood the severe winter of 1860-1, when the temperature, after a cold, wet, sunless summer, sank to 2° below zero. The same plant, now a large pyramid, without the slightest protection beyond that afforded by one or two common Hollies on the north side, has, since that time, passed through many a scathing storm, but I never knew a single twig a year old or a leaf injured by the weather. Here, on a high and rather dry bank, it is quite at home in a stiff calcareous loam, and would no doubt grow much faster on a dry sandy soil, but I question if this would be an advantage, as it starts early, and intending planters will please note, the young tips are sometimes blackened by late spring frosts. When this happens a second growth starts and ripens, but prevention being better than cure, I would suggest planting where it can have the full blaze of the midday and afternoon sun, whilst shade and shelter protect it from the east. Many trees, notably the *Cephalonian* Conifer and *Picea Webbiana*, although capable of withstanding our severest winter cold, being early growers sometimes suffer in the same way, but planters now get over this disfiguring difficulty by placing them on the west side of a hill, or where tall trees will break the rays of the morning sun until such time as hoar-frost will have passed away. This Holly is sometimes taken for *Quercus bambusaefolia*. Side by side they are, of course, quite distinct, but, like all the Japanese Evergreen Oaks, this one is a gem, and a worthy companion to *I. dipyrrena*.

ILEX LATIFOLIA.—Within 40 feet of the preceding we have a very fine tree of this noble Holly, but having been longer in the country, it is better known, although seldom met with. A native of Japan, it is supposed to be, and perfectly hardy, a plant fully exposed to the north and east having passed through the winter of 1860 with impunity. The leaves being very large, from 9 inches to 12 inches in length, shelter from cutting winds should, if possible, be secured for this handsome

and distinct species, and further north, like the Magnolias and Griselinias, it would certainly repay if it did really require the shelter of a wall. Worked on the common Holly, this species, like the preceding, is not fastidious as to soil, always provided it is well drained and rich enough to produce fine foliage, its chief ornament. This and *I. dipyrrena* flower freely and the first produces berries in fine seasons, but notwithstanding the fact that several varieties of *I. Aquifolium* growing close to them produce fertile seeds in abundance, I have never succeeded in getting these to germinate. Turning to one of the leading London nurserymen's catalogues, containing about fifty of the best species and varieties of Holly, I find names of useful kinds running consecutively. Some are species, and being specially adapted to certain purposes, I will enumerate them.

I. BALEARICA (the Minorca Holly).—Described by Loudon as "a very distinct variety of the common Holly, readily distinguished at sight by its yellowish green leaves, sharply acuminate, slightly waved at the edges, and with few prickles." Had Loudon seen large trees growing on our dry, calcareous loam, he might have said more in its favour, for with us the foliage is dark, dense, and remarkably bright, and the large coral berries, which the birds always leave till the last in the sharpest winters, are magnificent.

I. CORNUTA (furcata).—Introduced from China in 1848, and described as having leaves nearly quadrangular, each corner armed with a stout, sharp spine, besides a terminal one at the apex of the midrib. Very stiff and coriaceous, dark green, paler beneath. The leading type of several other species, such as *I. Fortunei* and *I. furcata*, which Mongredien, I presume, considers to be distinct. I planted the two side by side, and after some three or four years' growth, arrived at the conclusion that they were identical. *I. furcata* died, but *I. cornuta* is still alive and making slow, but sure, progress. This distinct Holly should be planted above the line of fogs and sharp morning frosts. It is a remarkably slow grower, and well adapted for front rows, for grouping in sheltered nooks, and winter bedding in the flower garden.

I. FORTUNEI OR *CRENATA*.—A very distinct species, with rather small, crenated leaves. A slow grower; consequently, like *I. cornuta*, well adapted for front rows and grouping in the winter garden. There is, I believe, a fine golden variety from Japan especially useful for winter bedding, and as an edging for beds and broad walks.

I. MADEIRENSIS.—This is a very handsome species, with light green leaves of moderate size. It is quite hardy at Eastnor, and forms a good, medium-sized standard, also a compact lawn pyramid, which does not readily grow out of bounds.

I. M. ATROVIRENS has very dark green leaves of large size; it is a free grower, and is strongly recommended for hedges, which it is said to form much more quickly than the common variety.

W. COLEMAN.

Cedars at Syon House.—The effects of the heavy fall of snow during the past winter are now to be seen in the destruction of many of the specimens of the above. Some of the largest plants have been quite spoiled, the entire tree being stripped of nearly every branch. Many of the other deciduous trees have also been injured to a great extent. This is to be deplored, as at Syon House some of the finest specimens that are to be found in the country are growing.

The result of tree planting.—Three years ago much of the lands westward of the Mississippi were considered almost valueless because of the generally believed unchangeable aridness of the climate. This has, however, now been altered. The change is the result of tree planting and cultivation of the soil. So far as the work has gone the effect produced has been wonderful. Cultivation and trees cool the air near the surface, rendering it so light that it has the same effect on the particles of water that the pressure of one's hand would have on a wet sponge.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

FLOWER GARDEN.

SPRING IN A NORTHERN GARDEN.

A FEW months ago you were good enough to insert in THE GARDEN a few remarks of mine on the winter aspect of my garden, and as spring is now at hand, and some hardy plants and flowers already lend a charm to the borders, perhaps I may be permitted to say a few words concerning them at this, to me, the most interesting season of the year. I am a great admirer of alpine plants, and as, for some mysterious reason, Box declines to grow in my kitchen garden, I use half-buried stones as edgings to the walks, and make small colonies of plants amongst old weather-worn, Moss-covered blocks, of which there is great abundance here. The stones are interesting also by reason of their great antiquity, being, in fact, the *débris* of the old Roman wall which formerly intersected this property, and I may remark in passing that the adjoining military road between Newcastle and Carlisle for the first thirty miles west of Newcastle was constructed upon the foundations of Hadrian's Wall, and which are still quite visible on the surface of the road at Heddon-on-the-Wall and other places—the wall itself having been demolished and utilised for the formation of the aforesaid road, and of sundry farmhouses and other buildings in the vicinity.

These stones are of many shades of colour, ranging between cool grey, yellow, olive, and deep red, the latter showing unmistakable evidence of fire action in former ages. The tints afford charming contrasts of colour with the deep green *Scyllas* and *Saxifrages* which clasp and over-spread the stones, and the green mossy carpets are just now pierced by the slender stems of *Scillas*, dwarf *Daffodils*, *Iris reticulata*, *Crocuses*, and *Snowdrops*. Here and there among the mossy blocks are snug nooks full of winter *Aconites*, *Hepaticas*, and varieties of silver *Saxifrages*—*pectinata*, *rosularis*, *Sturmiiana*, and *lanceana*, and a few of the spiny-tufted sorts, such as *Bursieriana*, *juniperina*, and a variety as yet but little known, resembling *juniperina*, yeleft *Boydii*, also with yellow flowers and beloved by sparrows, and therefore requiring protection while in bloom. *Saxifraga oppositifolia major*, a fine variety obtained from Backhouse, and which deserves to be more generally known, is now in great beauty. *Sempervivum californicum*, *montanum*, *Boutignianum*, *Laggeri*, and others nestle among and seem quite at home in the fissures of the stones.

I can strongly recommend these rock borders as unfailling objects of interest at all seasons of the year. They give no trouble, and every day almost as spring advances some tiny, but exquisite plant lifts its head above the ground and charms the eye with its modest beauty. This is especially the case just now when the rigours of winter are retiring before the ethereal mildness of gentle spring. *Sedum Lydium* and *Sedum glaucum* are capital plants for a rock border, and make charming cushions, and contrast well with the lowly bronze leafage of *Acena Nova-Zelandiæ*. *Arenaria balearica* is a very interesting plant, and is allowed to cling to the blocks and wander where it likes, even a little on the walk, upon which it throws out tiny feelers, as if try-

ing to cross to the other side, thus imparting to the path a picturesqueness and grace far beyond the reach of art, and immeasurably more grateful to the eye than the formal, stiff, monotonous Box edging.

Behind the stones are planted some of the best dwarf herbaceous plants—*Lithospermum*, *Gentians*, *Phlox setacea*, *Achillea umbellata*, and *Veronica candida* and *incana* (both very good silver-leaved plants), *Enocheras*, *Veronica repens*, *rupestris*, and *saxatilis*, flake *Carnations*, *Violas*, &c., and behind these a row of somewhat taller plants, as *Delphinium Bellalonna* (a gem), *Lobelia Victoria*, and *Anemone japonica alba*. So far, I had written in the pleasing belief that an exceptionally mild and genial spring had set in, but this morning on looking out, lo! what a transformation!—the beauties of the spring flower garden have departed, and the hills and valleys which yesterday were green with bursting vegetation to-day are clad with a thick coat of snow. The spring has evidently set in with its usual severity.

JOHN P. MULCASTER.

Bemmel, Northumberland.

SEEDLING PRIMROSES AND POLY- ANTHUSES.

WE raise many hundreds of these annually, because they are never so beautiful as when they produce flowers for the first time. No garden should be without a few clumps of Primroses—I mean of our native plants, and the first week in April is the best time to sow seeds of them. The most charming display of Primroses I ever saw was in Mr. G. F. Wilson's garden at Weybridge. He planted all the best varieties he could obtain and then left them to take care of themselves. His seedlings were self-sown, and were prettiest where the seeds had fallen on good ground amongst Moss or mossy *Saxifrages*, which kept the surface cool. The Primrose likes a cool bottom, and is more at home by a river's brim or on the shady side of a wood in damp, nutritious loam on pasture land than on sunny banks. My plan with seeds is to sow in pots or pans, filled with fine soil. The seeds are just covered over, and when the surface is made smooth I place over it a thin layer of green Moss in order to maintain a uniform degree of moisture in the compost. The pots or pans are plunged in a gentle bottom heat in a part of the frame where they are shaded from the sun. If the surface becomes dry during germination many of the seeds will be destroyed, and, on the other hand, if too wet and over-heated they will rot. The soil ought to be just moderately moist when the seeds are sown, and the Moss should be kept moist by lightly sprinkling it, and the pots being plunged in a moist bottom-heat, this will keep the seeds uniformly moist without wetting the medium in which they are sown. In about a fortnight most of the seeds will have vegetated, when the pots containing them should be placed in a cold frame. After the first plants appear, which will be in about three weeks, they are pricked out in boxes at distances of about 2 inches apart. The boxes may be kept in frames until the plants are established; after that place them out of doors in a shady situation. Such plants as these do not succeed well if freely exposed to the sun, at least in the south. We set them out a foot apart on well prepared ground about the end of June or early in July. Under such circumstances the leaves will meet together and form a compact mass. Those who have plenty of seeds to scatter freely in the open ground may think these details tedious, but it is the plan which I pursue with the small pinch of laced *Polyanthus* seeds we are able to save, and Primrose seeds gathered with great care from the choicest varieties.

One might imagine that Auricula seeds and those of the Alpine and Himalayan Primulas might be treated exactly like Primroses and Polyanthuses, but the same treatment does not answer for all of them. In the first place the seeds do not vegetate so freely as those of Primroses, and they do best if kept in a cool place. To this Alpine Auriculas must be regarded as an exception, as the seeds of these vege-

tate freely, either in a cool place or in a hotbed. Alpine Auriculas are supposed to be garden varieties of *Primula pubescens*, and really ought not to have been designated Auriculas at all. Auriculas, properly so called, are divided into four classes—green, grey, white, and self-edged. The seeds of these should be sown as soon as they are ripe, in July or in February. About a fourth of the July-sown seeds will vegetate soon after they are sown; the remainder will not do so until February and March, but the pots and pans containing the dormant seeds must be attended to for six months, when the second lot of plants will come up. Rather than have this trouble with them I have kept the seeds until February, and the results have been very satisfactory. The young plants should now be pricked out, say about a dozen in a 3-inch pot. Be careful to repot as they require it, and excellent flowering plants may, as a rule, be obtained in this way.

The seeds of the garden varieties of *Primula pubescens* are as easily dealt with as ordinary Primrose seeds. These produce beautiful varieties with yellow or cream coloured centres, having shaded edges of a rich crimson-maroon colour or purplish maroon. *Primula viscosa* from seed sports freely; the small white variety *nivea* produces lilac and purplish coloured varieties freely. The seeds of this we sow along with those of Auriculas, and treat them in the same way; indeed, most of the Alpine Primulas should be treated like Auriculas. All who have the means should annually raise seedlings of these beautiful spring flowers.

J. DOTCHAS.

Erica carnea.—This attractive early-blooming Heath succeeds admirably in South Wales, where we have four beds of it. Each of them is about 15 yards in diameter, and they have not been disturbed for upwards of twenty years. At the present time every inch of them is aglow with masses of cheerful pink flowers, and as open-air blossoms are by no means plentiful as yet, these Heath beds are greatly appreciated. This Heath should invariably be found in gardens of all sorts and sizes. I regard it as one of the most valuable of all hardy Heaths.—J. MUM.

Petunias in the open air.—As a rule the culture of Petunias in the open will only end in disappointment. They grow in a very straggling manner and the wind is apt to break the shoots off by the ground. I have known beds of them to be almost swept away at a time when they ought to have been in perfection. Their flowers are most flimsy, and rain soon disfigures them. Pegging down helps to prevent the shoots from being broken, but nothing will save the flowers from being disfigured, and all who plant them ought to do so with the understanding that they are most uncertain flowers with which to deal.—CAMBRIAN.

Violets on the Cotswold Hills.—A correspondent (p. 204) says he has been gathering a full supply of Violets all winter consisting of the tender kinds, such as *Neapolitan*, *Comte Brazza*, &c., and I presume from the open air, as he does not refer in any way to glass-protection, or other special culture, while here, within sight of the Isle of Wight, open-air Violets have been conspicuous by their absence. Even the hardy *Czar* and other single kinds have had their foliage destroyed by frost, and they are only just now pushing fresh leaves and making an attempt to bloom, the winter having been unusually long and severe. Our tender Violets of the kinds mentioned are blooming nicely in cold frames, but the few left in the open air look wretched indeed. If such good results can be realised on the Cotswold Hills, we must in future say but little about the sunny south.—J. C., *South Hants*.

Blue winter Windflower.—The *Anemones*, next to the *Gentians* and *Edelweiss*, have always been great favourites with the tourist, who never tires of describing the wonderful beauty they display in their native wilds. In the garden, too, however, the display can be equally beautiful if care be taken in the selection of a proper position, for on this alone as all gardeners know, success to a large extent depends. A few of the truly alpine kinds are showing flower just now, and though charming in their way,

they are not to be compared for vivid colouring and profusion with the early *Anemone blanda*, which is just now opening its large azure or deep sky-blue flowers. It grows about 4 inches or 5 inches high, and though nearly allied to the better known *Anemone pennina*, it may readily be distinguished by the black pointed styles, smooth sepals, and much darker flowers. It seems to stand exposure better than the Apennine Windflower, and we find it perfectly hardy and generally vigorous in the semi-neglected or wild garden. It should also be on every rockery in good, deep soil and fully exposed; thus treated it will flower freely in mild seasons soon after Christmas. It may be multiplied easily by division. *Anemone apennina* and *Anemone apennina alba* are both worthy of a place in every collection. They begin to flower later than *A. blanda*, and continue for a considerable time in beauty. *Anemone fulgens* seems to have suffered very much this spring through severe frosts following close on the mild weather we were having. The leaves seem to have been entirely destroyed, and many of the buds showing in the more sheltered places have also been nipped; our soil is light and sandy, and as the tubers ripen well in summer we never lift them.—K.

HARDY CYCLAMENS.

LIKE the greenhouse class of Cyclamens, there are many varieties of hardy ones with flowers ranging from pure white to reddish purple. Being perfectly hardy, they, as a rule, thrive best when planted under the shade of shrubs—in the rock garden or at the foot of a wall. To grow them successfully they should be planted in a free, open soil with plenty of good drainage, consisting of lime rubble and broken bricks. Some growers allow them to scatter their own seed, but it is advisable to collect it and sow it as soon as ripe in a well-drained pan filled with light soil. Give a good watering through a fine rose, and cover the surface of the pan with a piece of brown paper or Moss to keep the soil moist and place it in a cold frame, removing the covering from the pan as soon as the seedlings appear. When large enough to handle, pot into 3-inch pots, using a mixture of loam, leaf mould, and sand, and place them in a frame. To encourage growth as much as possible throughout the winter, air should be given plentifully until the following summer. When the leaves are decayed they may be planted out in their required places. When planting they should be buried to the depth of 2 or 3 inches.

Some years ago I remember seeing in the south of England a remarkably fine bed of Cyclamens. They were planted in a Rose bed, and during the late autumn and early winter the whole bed was one mass of flowers, varying from pure white to a deep red. Some tubers were quite a foot in diameter, and had as many as 200 blooms on them. The foliage also was very pretty, and retained its beauty throughout the whole winter and spring.

CYCLAMEN HEDERIFOLIUM will grow in almost any soil, but it thrives best when planted in a well-drained, rich border. We have some planted here at the foot of a wall, and with a little protection these were in full flower at Christmas. I have also seen them growing in a semi-wild state under the shade of trees and planted by the side of walks, but wherever planted they should not be removed, as they do not like being disturbed. The flowers are purplish red, striped with a lighter colour, and produced in great profusion before the leaves.

C. EUROPEUM is another species of which there are several varieties, producing flowers varying from pure white to a pinkish colour. This, with a little attention, may be had in flower from July to the end of December. This, unlike *C. hederifolium*, produces its leaves before the flowers.

C. COMMUNE, another useful species coming into flower when outside flowers are very scarce, is also noteworthy. I have seen this species growing on open borders one mass of flower from January to the end of March. Like other species, it has several varieties varying greatly in colour.

C. VERNUM is a late-flowering species, producing its flowers in March and April. Though perfectly hardy it is seldom seen in the open border. There

are many other varieties too numerous to mention but all worthy of culture, and if a little judgment is used this beautiful plant may be had in flower during the greater part of the year. OLITOR.

"**Bonnie Daffodils.**"—As we are now in, or approaching, Daffodil time, perhaps some of your readers might like to know that in Milton's own autograph of a copy of "Comus" in the library of Trinity College, Cambridge, he writes (lines 850-1)—

And throw sweet garland wreaths into her stream
Of Pansies, Pinks, and gaudy Daffodils.

A far prettier epithet would have been—

Of Pansies, and of *bonnie Daffodils*.

The epithet "bonnie Daffodil" is surely more appropriate than "gaudy." Why Milton altered it in the printed editions I cannot say. The printed editions have *Pansies*, a common old spelling, but Milton's own spelling, according to Warton and Todd, is *Pansies*.—RICHARD HOOPER, *Upton Rectory, Didcot*.

Outline drawings of Daffodils.—We are half-ashamed of engraving feeble ghosts of Daffodils, and warn friends that all *Narcissi* intended for engraving in THE GARDEN must be in future photographed or drawn in the true way. The difference is that of life and death. We do not agree with Mr. Walter Crane that outline is the beginning and the end of art; he is wrong! Outlines and diagrams are but the feeblest substitutes for true art—abstractions, only excusable in savage men.

White Daffodils.—All the Irish white Daffodils are now in flower at Temple Hill, Cork, in congenial soil. Any member of the Daffodil Committee can have blooms posted of *Leda* for comparison with Mr. Barr's *tortuosus*, and of Bishop Mann when in full perfection, which it will be about the 20th. It is now (March 14) over a foot in height, and will then be 18 inches. When the discoveries of botanical travellers in Portugal relative to white Daffodils are made known, will it be quite fair to keep such names registered as Bishop Mann, *Gladys*, *Leda*, *Colleen Bawn*, &c.—*i. e.*, should such be re-discovered? These have been shown at South Kensington from Ireland, and surely if travellers match them with wild forms, the sooner we stay our hands with names the better, for where shall we draw the line? If the names just quoted are allowed to stand distinct, selections from *pallidus præcox*, *variformis*, *wild bicolors*, &c., should be tolerated. There are many beautiful Daffodils, regular gems in fact, in the wild bicolor section and *variformis*. Let us therefore have the matter settled, as from what I see in THE GARDEN (p. 203) bulbs found in gardens in Ireland are to be all re-matched from their native country; yet when we consider that the extent of the Pyrenees is about equal to that of Ireland, the job will be rather trying. When, however, Mr. Maw is to be the advanced guard, I have no doubt that some good work will be accomplished; and as regards the Chiswick trial, that is all premature, and Ireland still holds the field as to white Daffodils until the travellers return with their booty.—A MEMBER OF THE DAFFODIL COMMITTEE.

Gaillardias from seed.—There are few more attractive summer flowering plants than these, and in addition few can be more cheaply and readily obtained. They are suitable for planting in mixed borders, and are still more effective when massed in beds as a substitute for some of the better-known bedding plants. The seed ought to be sown not later than March in pans of fine sandy soil, and only lightly covered with more of the same. Placed on a mild hot-bed shaded from bright sunshine and kept uniformly moist, the seeds will soon germinate, and before the seedlings are far advanced they should be transferred to a shelf near the light in a cool house, or be placed near the glass in a frame. When about 2 inches high or before they crowd and spoil each other, the seedlings should either be potted singly in small pots, or be dibbled thinly in boxes or pans of good soil. If shaded and kept rather close for a time they will quickly become established, after which cooler treatment should be given, the aim being to have

strong sturdy plants for putting out late in May. It is not advisable to plant them in very rich ground, as when once well established they seem to be more floriferous on comparatively poor borders and beds. The best display of the double flowering varieties I have yet seen was at Heytesbury House, Wilts. They were planted in a hot sunny border, and were singularly effective long after the majority of the ordinary summer bedding plants had been cleared. I think the old *Gaillardia picta* is the prettiest and most useful sort, whether for borders or for affording cut blooms. It mixes beautifully with other cut flowers in almost any kind of vase. *G. grandiflora* is of a more vigorous habit and later in flowering. A few plants of this sort may with advantage be shifted into 6 inch pots, and will be found useful for the autumn decoration of greenhouses and conservatories. Seed of *G. picta Lorenziana* also germinates freely, and these double forms are quite as attractive as the singles, especially when planted in patches of three or more plants, a way in which we prefer to put out this class of border flowers.—W. I.

Violets.—One has but to walk along the London streets to observe that the flower-girls have few English Violets, but plenty of imported ones, chiefly double pale blue, fresh and sweet. At home Violets have materially suffered, and perhaps as much from fogs and hoar-frost as from snow. Just now, when in ordinary seasons there should be an abundance of flowers of both the Czar and Russian, they are not only flowerless, but almost leafless, the former having suffered most. This is productive of severe loss to the market growers, many of whom expect to be in receipt of from £50 to £60 per week from Violets. When the bloom does come this year it will be late, and in the form of a glut. Double Violets, which thrive so well in the open, and make fine plants with robust leafage up till Christmas, then begin to show signs of decay; the leaves rot and disappear, and the plants are greatly injured. This is chiefly the result of fogs, which are very dense and destructive in West Middlesex. Not only do the growers suffer, but the women pickers suffer also, and, through the resulting loss of wages, the local trade; so that failures, even of this comparatively unimportant kind, are widespread in their effects. It is an undoubted fact that no such good Violet seasons are now experienced as were wont to be fifteen years ago.—A. D.

Colchicum neapolitanum.—Though, strictly speaking, this is an autumn-flowering species, the form which we grow, and which we believe to be in the trade, flowers in re or less during winter when the weather is mild. At present it has thrown up several of its pretty, well-formed flowers, which are somewhat similar to those of *Crocus autumnalis*, but smaller and neater. I was at first inclined to doubt the constancy of this habit of spring-flowering, but on reference to notes I find that the plant has not varied since it was planted in 1882, although once or twice the display has been greater than that which we are now having, owing probably in this case to the prolonged severe weather. The flowers, which are mauve-lilac, are just now very welcome. *C. crociflorum*, of Regel, is just making its appearance. It is quite distinct from all the other types as regards colouring. As its name purports, it very much resembles a *Crocus* belonging to the biflorus section. The flowers, which are small, are milky-white and about the same size as those of *Crocus biflorus*, with three dark purple markings running down the outside of the segments and losing themselves in the purple tube. It is a sweet little flower, only equalled by *C. luteus*, a species with orange-yellow flowers of rare merit for spring decoration.—K.

SHORT NOTE.—FLOWER.

Double flowered Periwinkles.—In my note upon the hardy *Vincas* (p. 161) I inadvertently stated that there were double-flowered varieties of all the single kinds in cultivation. This is not so, as no double white-flowered form of *Vinea minor* has been seen, and, like a double white Hepatica, it is a plant much to be desired. A nurseryman friend reminds me of my error, and adds that he is ready to give a substantial sum for the first double white *Vinea minor* that is forthcoming. He will probably have to wait a long time.—W. G.

LAMBTON CASTLE.

THE first of the accompanying illustrations of Lambton Castle, the seat of the Earl of Durham, shows the front of the building that faces the river, to which the ground descends precipitately, as is shown by the presence of the high retaining wall rendered necessary to support the terrace. This wall is partially hidden by trees, the heads of which barely reach its top. Southwards, on the opposite side of the river, the land, which is well clothed with timber, continues to rise for a mile or more, as it also does for some distance northwards in the rear of the castle; consequently little is seen of the place from a distance, or of the surrounding well-kept grounds. The castle is a noble stone building, extensive, and well proportioned, and agreeable in colour. The second view (p. 253) represents a portion of the western side, as seen from the grounds in that

became a question as to pulling down the building and erecting it elsewhere, or the alternative course of shoring the ground up in the old workings. The calculation made by competent authorities was, I believe, that the cost of the respective courses would be about the same. The shoring up of the ground was therefore adopted, and has been effectual, but it turned out to be a herculean undertaking, occupying a good many years, and swallowing up millions of bricks. Scores of tons of wrought iron were also used in bolting the walls together, rendering the building probably stronger than if nothing had happened to it, and so well has the work been done that no trace of the damage or of the remedies employed to set it right is perceptible either inside or outside.

The gardens are extensive, and in all depart-

and is cheaper than silver sand and equally good.—OLITOR.

ROSE GARDEN.

T. W. GIRDLESTONE.

ROSES TO LOOK OUT FOR IN 1887.

AMONG the new Roses that will probably be to the fore at exhibitions and elsewhere during 1887, there are about a dozen varieties whose appearance will be watched for with especial eagerness by enthusiastic rosarians. It really seems as if, after one or two very dull and unproductive seasons, 1887 were likely to prove a Jubilee year of the queen of flowers as well as of Queen Victoria. Several novelties that have already attained a wide reputation are to be sent out this year, or having been distributed in England last spring, may be confidently expected to display their

Lambton Castle, from the south-east. Engraved for THE GARDEN from a photograph.

direction. Lambton Castle at the present day may be said to be unique amongst buildings of this, or possibly any other, country. The ground on which the castle stands, in common with that of the surrounding district, rests on a coal-field, the workings of which had been driven underneath the castle. When the coal was exhausted, the pit, as usual, was abandoned and was allowed to fill with water. For a time nothing unusual occurred until a powerful pumping apparatus was put down in one of the pits at a distance; this not only removed the water, which it was intended to do, but rendered the old workings under the castle dry as well. After a time the surface began to subside so far as to affect the foundations of the building, the result being that some of the inner walls cracked to an extent that admitted of a man's arm being passed through the openings. It then

ments cultivation is thoroughly well carried out. In fruit especially Lambton has a well-deserved reputation. T. B.

Sea sand for plants.—"Is sea sand injurious to plants?" is a question in answer to which many would doubtless say, "Yes." Until recently I, too, entertained the same opinion, but I find that harm occurring through its use is the exception rather than the rule. Here we use it for all purposes for which sand is required just as it is carted from the shore, and ordinary stove and greenhouse plants seem to thrive luxuriantly in it; Carnations are also benefited by its use. Some time ago Carnations could not be grown here until sea sand was applied plentifully about their roots, and now they do well. Sea sand being, as a rule, of a sharp gritty nature, is superior to the fine, soft sand which is used in the majority of gardens for keeping the soil open,

charms in many gardens, and at not a few exhibitions during the summer. First and foremost, Her Majesty (Bennett, 1886), whose magnificent, clear rose-coloured blooms, so finely exhibited at the South Kensington show of the National Rose Society and at the Crystal Palace in 1883, must be generally remembered, will probably grace some of the Rose shows with her truly royal presence, although those who do not possess cut-backs of this Rose must not count too much on obtaining flowers, for its perpetual character is not yet fully established, and though, like Mdme. Gabriel, to which it bears a certain resemblance in many points, it may prove autumnal-blooming on established plants, it does not appear to flower as a maiden. Another of these very large and vigorous light Roses comes from that veteran raiser, M. Lacharme, whose seedlings are almost invariably worth growing. The raiser of Victor Verdier, Xavier Olibo, Alfred Colomb, Louis Van Houtte, Charles Lefebvre, Captain Christy, Mdme.

Lambard, and Violette Bouyer—to name but a few of his triumphs—has sent out fewer uninteresting Roses, and more varieties of the first rank, than any other grower; and his name has come to be so far held as a guarantee of excellence, that his novelties are awaited with the keenest anticipation. Clara Cochet, the seedling distributed in this country for the first time last spring, is a Hybrid Perpetual of exceedingly vigorous growth, with very large, bright rose-pink flowers; and if it does not actually surpass (as it has been said to do) all previous Roses from this raiser, it is at any rate not likely to lower his great reputation.

With hardly less interest than the Hybrid Perpetuals of M. Lacharme are awaited the Tea Roses of M. Guillot, who, in addition to the notable hybrids, Horace Vernet and La France, has sent us such sterling Tea-scented varieties as Madame Falcot, Catherine Mermet, Comtesse de Nadaillac, Hon. Edith Gillord, and Madame de Watteville among many others. His new Comtesse de Frigneuse has a deep, clear yellow flower, pure in colour, and with a very large petal; is, as far as has been seen at present, free-flowering and vigorous; and has been exceedingly favourably reported on this winter from America, where growers have a happy knack of speaking their mind about novelties with wonderful plainness and promptitude. Two very promising new Roses come from America, one a Tea, and the other one of the so-called Hybrid Teas. The former, named The Bride, has been very generally flowered, and is on all hands well spoken of. It originated in the garden of Mr. J. May, of Summit, New Jersey, as a sport from Catherine Mermet, from which beautiful Rose it appears to differ only in colour. The habit of the plant and the type of flower are identical with those of the parent, but the petals of The Bride, instead of being rose-coloured, are quite white, with a faint tinge of lemon at the base. The flowers are large, well formed, freely produced early and late, and open well; and, in fact, as far as is possible to judge from one season's experience, the variety will constitute one of the most valuable of recent additions. The new American Hybrid Tea referred to is called American Beauty (Bancroft), and produces large deep flowers, with a fine petal, and of a red colour. Whether this red may not be of rather too purplish a tint only further experience can show, but the variety is so free, so thoroughly autumnal, and so phenomenally fragrant, that it is sincerely to be hoped that it may not be found guilty of the charge of dull colour, from which, of all the other red Hybrid Teas, the invaluable climber Reine Marie Henriette alone stands acquitted.

A new Rose, however, of the brilliancy of whose colour there is no question, is Mr. Wm. Paul's seedling from A. K. Williams, which received a first-class certificate from the Royal Horticultural Society in 1886 under the name of Grand Mogul. This Hybrid Perpetual produces a large imbricated flower of the same type as its parent, but of a more vivid crimson, shaded darker, and lighted with an almost scarlet flush; and if it is only as constant and as thorough an autumnal flowering variety as A. K. Williams, it will prove an acquisition. There is also a new English Tea of great promise, namely, Viscountess Folkestone (Bennett), which was well shown at the Crystal Palace last July. It produces large rosy-tinted flowers, with rather a salmon shade, something in the way of, but brighter and fresher coloured than, Souvenir d'un Ami, and is of good form and substance.

Two other seedlings of this raiser are being distributed this year, both of them Hybrid Perpetuals. Oddly enough, one of them, The Puritan, named after the winning yacht in the recent Anglo-American yacht races, is not described at all in the preliminary announcement, even as to colour; but the other, Mrs. John Laing, which was awarded the gold medal of the National Rose Society, at their exhibition at South Kensington as a first-rate novelty in 1885, is well known in this country in the cut state, having been finely shown at South Kensington and at the Crystal Palace. It may perhaps best be described as an

improved Monsieur Noman, being a large, deep flower of a pale rose colour, very full, and apparently very constant; by some considered more refined in outline, and consequently preferable to Her Majesty. But comparisons are odious, and there is ample room for both varieties, which are thoroughly distinct.

There are three new Roses being now sent out by Messrs. Alexander Dickson & Sons, of Newtownards, Ireland, of which a good deal has been heard, and not a little been seen, especially at some of the northern exhibitions, during the two past seasons. Two of these are Hybrid Perpetuals and the third a Tea-scented variety, while to one of the former no less than seven, and to the last four, first-class certificates have been awarded by such leading Horticultural Societies as those of Dublin (R. H. S.), The West of Scotland, Liverpool, &c. Earl Dufferin, as this frequently commended Rose is called, is described as "a Hybrid Perpetual of a bushy and vigorous habit, with dark green foliage; an early, continuous, and late bloomer; flowers large, full, and finely formed; colour rich brilliant velvety crimson, shaded with dark maroon; petals large and very smooth." In spite of its numerous certificates, however, the best recommendation of this Rose to exhibitors will probably be found in the fact that at two Rose shows in 1886, a bloom of it was selected by the judges as the best bloom in the show, a test of excellence in competition with all the leading varieties which cannot be gainsaid. Lady Helen Stuart is described as a "Hybrid Perpetual of strong growth; a most continuous bloomer, and very fragrant; colour bright crimson-scarlet, with beautifully smooth petals of great substance;" and Miss Ethel Brownlow as a "Tea of most robust branching habit; foliage rich and handsome; flowers large, of great substance and magnificent form, always opening well and lasting a long time; petals very thick, smooth-edged; colour bright salmon-pink, shaded yellow at base of petals." It is much to be regretted that it has not been found possible to exhibit these varieties at some of the southern Rose shows; but it may be hoped that they will be in evidence at the northern exhibition of the National Rose Society at Edinburgh on the 13th of July this year; and, at any rate, their appearance generally will be awaited with keen interest.

Of the above dozen promising novelties, only four are from abroad, and of those four, two are from America. There is no doubt that British raisers are now taking the field that has been too long monopolised by Continental growers, and numerous advantages may be anticipated to all concerned; notably one—that the new varieties will get names which it shall be possible to articulate without danger of leek-jaw.

SHORT NOTES—ROSES.

Rose The Bride.—A very pretty box of eighteen blooms of this new American white sport from Catherine Mermet (The Bride) was shown by Mr. P. Gilmore, of Sheffield, at the meeting of the Royal Horticultural Society at South Kensington on the 31st inst., when this charming variety was deservedly awarded a first-class certificate. Many of the blooms staged displayed exactly the characteristic form of Catherine Mermet, and the white of the petals faintly tinged with lemon at the base was quite uniform in tint throughout the box.

Rosa indica.—Another interesting Rose was shown by Messrs. Paul & Son, of Chesham, namely, a single form of *Rosa indica*, probably a representative type, if not the actual species, from which the numerous tea-scented Roses of gardens have been raised. It should make an attractive addition to desirable single Roses, as the flowers have large petals of a beautiful flesh colour.

Rose hedges.—Mr. Wilson has suggested using *Rosa rugosa* for Rose hedges, but if the efficiency of the hedge be a consideration, an even stronger and more formidable variety or species of the ferocious section for the purpose is *R. kantschaber*, which throws up its truly ferocious shoots with great vigour. A much stronger-growing form of Sweet Brier also than the common type, and also better adapted for use as a hedge-plant, will be found in the double marbled Sweet Brier, which has semi-double, very bright rosy-coloured flowers, and is, like most of the rubiginosa, a most prolific seed-bearer; whilst its immense erect shoots, 8 feet to 10 feet long, and covered with great hooked prickles, constitute a barrier by no means to be negotiated with impunity.

ROSE GROUPS FOR ODD PLACES.

MR. GIRDLESTONE'S timely remarks on the grouping of Roses recall some interesting features of ancient landscapes that are seldom reproduced in modern times. Among these some of the most cheering were Rose groups in woods, or as accompaniments or fringes to avenues and woodland walks. Rose groups in unexpected places formed some of the most cheering and pleasing surprises in not a few of the older gardens. No doubt these sources of surprise were often developed to absurd extremes, which led to their being entirely banished from many of our finer landscapes. Such surprising exhibitions of statuary, vases, fountains, as disfigure rather than adorn one of the loveliest vales in England at Alton Towers, the squirting fountain that suddenly and impertinently drenches the enthusiasm of the beholder of the fernery at Chatsworth, and the grotesque forms of not a few of the fine shrubs at Elvaston, have done much to cover surprises in landscapes with ridicule. Still, there is room for their moderate exercise in most gardens. It is no more needful for a garden to be unfolded all at once than for the plot of a novel to be set forth in its preface, if it has one. The landscape beauties of gardens should unfold as night melts into day. No one who has carefully watched this gradual lighting up of Nature but must have felt it to be a successional series of surprises—new features, fresh beauties spread over all the distance from darkness into light. So in degree should also be the unfolding of a landscape. To concentrate its beauties into one spot, and thrust them on the bewildered vision all at once, is like stepping at once from midnight into noon. All the most beautiful pictures have been crammed as it were into one room, and most of the other walls are bare. The sweetest harmonies of colour and form have been crowded into one spot, and the major portion of the landscape is silent or bald.

The remedy alike for this congestion and poverty of beauty is to be found in a wider diffusion, a freer and more natural distribution of its elements and materials. Never were we enriched—I had almost written encumbered or embarrassed—with such a profusion of material for charming and varied landscape as now. The wealth of the temperate vegetation of the world has been pouring in upon us for years, and is not seldom distributed in the most grotesque and unsatisfactory manner. What is now most needed, and that want promises to be met soon, are heads and hands to distribute the rich materials in question with more catholic and cultured taste.

Roses will probably be the first and the last to participate in the coming *renaissance* of landscape gardening. Considering their matchless beauty of leafage and bloom, their inimitable sweetness, their almost infinite variations of habit and stature, their striking and varied capacity for effect in landscape, it is surprising how little and what wretched use has been made of them for the formation and enrichment of garden and woodland scenery. Roses are ever pleasing, always welcome and beautiful. But their results in landscape have been too often nil, or a blot. The chief reason for this in the past has arisen from the carrying of the individualism of Roses to extremes. Each Rose bush or standard had to stand alone or at some considerable distance from its fellow, and it is no reflection on the substantial merits of Roses to add that few of them were strong enough as landscape plants to bear the test of such severe isolation. Some of the stronger ones managed to fill their appointed niche creditably when in full flower and leafage, but when both disappeared, Roses cut a rather sorry figure in the landscape. In the case of the majority, however, they seldom proved satisfactory at their best: for, indeed, it was and is impossible to make single or even groups of ordinary garden Roses form satisfactory features in the general landscape. While as for beds or rows of closely-pruned, stiffly-trained standards, it passes the art of the rosarian or artist to mould them into picturesque or pleasing forms.

The bolder grouping of the freer-growing Roses in unexpected places, and the giving them the power to run as they list, with little or no pruning or training, would do much to develop their landscape merits. The landscape effect of skilful grouping far outstrips any mere mechanical aggregate of numbers. For example, six Roses in a group are not merely six times as effective as one, but thirty-six or even fifty times more striking; and so with any other number. Again, surprise groups are, as a rule, far more telling than those duly discounted beforehand. One visits a garden reported to contain from one to four thousand Roses. We not seldom leave such, astonished to find how infinitesimally small or even nil the landscape effects of such gross aggregates of Roses can be toned down to. On the other hand, you come on a few groups or beds of Roses unexpectedly in the course of a woodland walk, and the effect is pleasing and effective, far beyond any mere mechanical proportion to the numbers of plants or size of groups. For example, reaching the summit of a rising walk, a small valley suddenly opens before you. Its opposite side and bottom are furnished with beds and groups of Roses. Looked down upon from an elevation of from 60 feet to 100 feet, every leaf and flower, as well as the outline of the groups and beds and grass or gravel divisions, are thrown back to the eye with a charm and a clearness impossible under other conditions. Elevation as well as distance lends enchantment to the view, and the very fragrance gains fresh sweetness as it mingles and mixes its odour on its way up to the beholder. Rose rests, again, in some secluded spot alike in the garden, pleasure grounds, or home woods, are equally welcome as shady seats, and when skilfully managed, which they seldom are, are as pleasing and satisfactory features in the general landscape. But these, where they exist, are mostly too prominent; note, for example, the Rose garden with many arches or bowers at the Crystal Palace; an ironmonger's shopful of iron perched against the sky, proclaiming to all the world a roseroy in which the iron for many years predominated, and which up till now has furnished little shadow and less retirement to its many tired-eyed and weary-footed visitors.

Rose arbours or mounts may prove welcome rests indeed to visitors if they furnish shadow as well as rest by the way. But they are all the more welcome if they can be so posted as to be seen but little, if at all, till a sudden turn or opening usher one into their friendly shade and refreshing rest rendered doubly welcome through being unexpected. Neither is it necessary that so-called Rose arbours or rests should stand out bleak and bald, generally marring rather than enriching the surrounding landscape; on the contrary, it is generally possible to link on, as it were, groups or beds of Roses to the bases of Rose rests, thus forming easy and natural stepping-stones between the more or less formal Rose rests and the more natural features of the shrubbery or wood beyond. A great deal may also be done to bridge over the gulf between art and Nature in Rose rests by allowing the plants on the latter to run out freely to meet and mingle with the more natural vegetation in their immediate neighbourhood. Nothing has crippled the landscape effects of Roses so much as restrictive training and severe pruning. The usual close pruning of Roses entirely unfits them for taking their proper place in landscapes; neither is there necessity for it. Were the show tent the ultimate or only goal of all Rose blooms, there might be reason in close pruning, but as landscape effectiveness depends rather upon numbers of blossoms than size or individual perfection, the more flowers, as a rule, the more effective the landscape. Certain thinnings maybe are needful to preserve the health and prolong the life of our Roses, but beyond this the knife or shears should hardly be felt if our Roses are to assume their due place and power in the adornment and enrichment of our landscapes. D. T. F.

English Rose The Puritan (Bennett).—This, which, like Her Majesty, is coming into the hands of

English rosarians via America, resulted from a cross between Mabel Morrison and Devonensis. The flowers are said to resemble those of Baroness Rothschild in form, but to be of a creamy or waxy white tint. The variety is reported as blooming with great freedom, while the flowers have the valuable quality of remaining fresh for a considerable time in a cut state. Assuming that its parentage is correctly reported, it is satisfactory to observe that in the English circulars the novelty is offered as a Hybrid Perpetual and not as a Hybrid Tea, an indication, it may be hoped, of an intention to discard the latter confusing and unnecessary term.

Rose Clara Cochet.—Lacharme's new Rose, according to accounts from Germany, is likely to prove one of those very vigorous light-coloured Hybrid Perpetuals which must not be pruned too hard, or it will be all growth and no flowers. Roses of this class are often not very free as maidens, but in spite of this Clara Cochet is already highly recommended by the German as well as by the French growers.

Rose Her Majesty is another Rose which must be only moderately pruned to ensure flower. This variety is evidently hardy enough, for its immense long shoots appear quite uninjured by the 25° of frost to which they have this winter been exposed unprotected, the buds already swelling to the very tips of the shoots, and the piths where the shoots have been cut being quite fresh, and not at all discoloured.

FRUIT GARDEN.

W. COLEMAN.

THE MULBERRY.

THE Mulberry, like the Quince and the Medlar, does not stand remarkably high as an edible fruit, and certainly it is not profitable, yet withal, the produce of the black variety, *Morus nigra*, is grateful, very wholesome, and highly appreciated by those who have acquired a liking for its sub-acid flavour. In past ages, when choice edible fruits of all kinds were less plentiful than now, the Mulberry was more or less planted throughout the kingdom, and being a slow-grower and long-lived, many grotesque specimens of immense age are still met with near the crumbling walls of old monasteries and in the best-kept gardens where the destruction of centenarians is regarded as sacrilege. Whether these relics of the past were planted specially for their fruit or their leaves when our forefathers embarked rather extensively in a British silk industry, which, like Tobacco culture, did not pay, we need not pause to inquire—suffice it to say, they have handed down to us extremely quaint forms which all lovers of Nature admire. Being short-grained and brittle, their peculiar habit of growth renders old trees liable to be broken by wind, the weight of their foliage, or by snow; but, being tenacious of life, they have a wonderful knack of casting their huge branches on their knees or their elbows, where, once they touch the earth, they strike root and throw up fresh shoots, which grow up as protectors to their parents. In this way a very ancient tree on the lawn at Stoke Edith, near Hereford, has dropped its branches one by one, which, in their turn, have grown into aged, hoary trunks, although hardly anything is left of the original. This rather extensive family of comparatively young trees now covers a very large space just in the right place; they produce bushels of bright black fruit annually, and form a most pleasing and refreshing contrast to Nesfield's clipped Box and coloured gravels hard by.

PROPAGATION.—From the preceding remarks the young aspirant to silk manufacture will gather that once planted in deep, rich soil, the tree will perpetuate itself through many generations. But where it does not already exist, fruit-bearing trees can be established in a very short time. Budding, grafting, and propagation by means of layers and cuttings are more or less practised by the trade. The black Mulberry comes true from seeds, and suckers make good, but some say sterile, trees. This fact, if fact it is, however, makes little dif-

ference, as such trees being free and kind, make excellent stocks for trained trees or standards, which begin to bear fruit at the age of six or seven years. Cuttings of the past year's wood 1 foot or 2 feet in length slipped off with a heel and let into the ground like Currant cuttings in the autumn soon strike root and make the best of plants for general purposes, but speed being the order of the day, the short cut to fruit-bearing trees is by means of large boughs, sometimes called truncheons, which may vary in size from 3 feet to 10 feet or more in height when let into the ground. The proper time to sever these large pieces from the parent trees is early autumn when the foliage is ripe, and the better to prevent wind-waving they should be let in some 18 inches, firmly rammed, and steadied with stakes, as we always support newly planted fruit trees.

SITUATION.—Although the black Mulberry is said to form a low stunted tree in Iceland, there exists but little doubt that it is a lover of heat, especially when in our temperate climate it is reflected by sheltering walls and buildings. Moreover, it revels in a deep, rich, warm soil, free from stagnant moisture; therefore, where these conditions do not exist, a sheltered nook fully exposed to the sun should be well drained and enriched with good turfy loam and leaf mould. These remarks, of course, apply to trees which are grown for their fruit, for, like all other edible fruits, there are Mulberries and Mulberries, and in order to have them in perfection they should be as black as jet, full of juice, and not unlike a large rich Blackberry. When planted for ornament, extra warmth is of less consequence, but being a late-leaving tree a good site should be selected, if only to extend its season of beauty. When properly planted, the tree generally takes care of itself without the aid of the pruner. When young, it is, however, a good plan to shorten all strong horizontal branches, and gradually to work it up into a clean-stemmed, round-headed standard.

GENERAL CULTURE.—When grown on the open lawn with perfect drainage beneath its roots, a given space round the bole should be kept free from Grass, which not only keeps the soil cool, but robs it of a great deal of moisture. Rich mulchings composed of highly concentrated stimulants that will keep in moisture without checking the influence of solar heat are advantageous to old fruit-bearing trees, but solid masses which prevent the soil from attaining its average summer temperature should be avoided, not only here, but wherever fruits of other kinds are valuable in proportion to their high flavour. Whilst re-venting water in a cold stagnant form, the Mulberry enjoys copious libations in summer, and very often casts its fruit when this element is not forthcoming during long periods of drought. Further, being liable to attacks of red spider, want of water fosters the enemy when the foliage becomes brown and rusty-looking, and although it unfolds late in spring it falls prematurely in the autumn.

VARIETIES.—*Morus nigra*, the common Mulberry, a native of Persia, and introduced three and a half centuries ago, is the only variety worth growing for its fruit, and the abundantly produced heart-shaped, rough, and coarsely serrated leaves rendering it unique among other deciduous trees of totally different habit, it is generally selected for the dual purpose of producing fruit and foliage. Silkworms devour the leaves, but it is to two varieties of *Morus alba*, a native of China, that the French and Italians look for their supply of leaves. The fruit of this species, which is white, is not considered fit for food, but that of the two cultivated varieties, *M. multicaulis* and *M. Morettiana*, is black and edible. The white Mulberry is considered more tender than the black; it grows much faster, is less enduring, and is highly impatient of stagnant water. Its leaves are comparatively smooth, very succulent, and contain much glutinous matter which gives tenacity to the silk produced by the worms fed upon them. Calcareous, sandy, or gravelly soils rest-

ing on dry rolling ground produce the finest quality.

Merus rubra, a native of North America, like the preceding, is a rapid grower, and makes a tall tree. It produces an abundance of leaves, and the fruit is said to be tolerable, but it is only from the landscape planter's point of view that this and *M. alba* should be looked upon in this country.

The black Mulberry makes a very handsome wall tree where it produces and ripens its fruit in the highest perfection. It is also well adapted for pot culture under glass.

DIGGING AMONGST FRUIT TREES.

WE have for some years past given up digging amongst fruit trees and bushes as far as possible; when compelled to cultivate the soil near them we use steel forks, and keep spades at a respectful distance. We give, however, a good top-dressing or mulching of manure every winter. There is hardly any substance that will rot that does not make food for fruit trees; we, therefore, spread the mulching around the bases of the trees, and occasionally over the whole surface, removing anything that will not rot. Under this treatment the roots form a regular network close to the surface; these are the roots that make trees fruitful, and although our soil is shallow and resting on gravel, we get very healthy trees, with scarcely a trace of disease of any kind. The mulching not only prevents drought from affecting the roots, but it forms a medium from which they derive food. Our soil is not strong enough to produce large trees, but it grows small and very fruitful bushes, that show as good a return for the space they occupy as the most approved fruit trees can do, and in this way very much of what is at present unremunerative land might be brought into use for fruit culture. It is from trees in comparatively shallow soils that the earliest fruit can be gathered, and by extra care in mulching to keep the roots on the surface good crops may be secured. I do not think that bush fruits need to be dug amongst, for with plenty of mulching on the surface the soil does not get hard, and the digging breaks the best roots or turns them up to drying winds. Raspberries and Strawberries do decidedly best in firm soil; in fact, we take some pains to tread it around the crowns at this time of year. Autumn-planted ones are liable to get their roots so loosened by frost that they perish from exposure before they get fresh hold of the soil if not trodden in in the way just named. Old beds, too, are much benefited by a little pressure, at least in light soil. Raspberries do not produce shoots all over the ground when kept firm at the root, but push up a few canes close to the parent stock; and the best bed of Gooseberries I ever had never had a spade or fork used amongst them. I would therefore recommend all interested in the subject of profitable fruit culture to try a portion of their stock without any digging, and devote the sum saved thereby to purchasing manure.

J. G. H.

English and American Apples.—When "A. P." (p. 166) speaks of American Apples being superior to English in colour and beauty only, I think he is surely subordinating his palate to his patriotism. Mr. Gilbert (p. 222) knows better, or has a more sensitive mouth; it is not with a view to red and yellow only that he advises English gardeners to set to work at raising seedlings "to match the American." Not only do I consider Newtown Pippin to be superior all round to any English Apple, but my sense of what is good tells me that such a common and cheap American variety as the Baldwin possesses, when in perfection, a crispness, juiciness, and briskness of flavour which can scarcely be found in English Apples. Our Ribston is supreme in rich flavour, but is leathery in texture; Blenheim is a fine, handsome Apple, very prolific and serviceable, but it is apt to be mealy when quite ripe, and can never be called crisp, brisk, or juicy—epithets which are deserved by so many of the American sorts. Mr. Gilbert is right; there is a great future in England for Apples with fresh blood in them.—G. H. E.

Strawberries at Twickenham.—A curious instance of the capacity of soil to carry fine crops of

Strawberries successively for a long series of years may be seen in Mr. Richard Clarke's garden at Strawberry Hill, Twickenham. There, almost without a break on a long, broad, south border, and, indeed, in nearly all the garden, Strawberries have been grown for some twenty-five or thirty years, and the plants and crops seem even now to be as good as ever. Of course, the plants do not remain above three years, and a considerable portion is renovated every year. The plants are usually those that have undergone a gentle forcing. In a market establishment such as this it is found most profitable to force moderately, as the best market, allied to best crops and richest coloured fruits, is found during the months of April and May. As many thousands of plants are grown under glass, there is always a considerable bulk of old pot soil at command, and this proves most serviceable in helping to replenish the garden ground. Mr. Clarke grows Sir Charles Napier and Garibaldi chiefly, the former being the most favoured.—A. D.

PEACHES INDOORS AND OUT AND MELONS.

MR. GILBERT, I see, says that Peach-house building is "overdone," which, considering that the more gardeners and their employers see of Peach houses properly managed the more inclined they are to build, is rather a doubtful assertion. We even hear of fruit growers for the market building Peach houses on an extensive scale. I like to hear of successful Peach growing in the open air; it shows careful culture, and might be encouraged where, for any reason, glass houses cannot be had; but if it comes to a question of which is the best way in which to grow Peaches in this country, under a glass roof or in the open air, then I say under glass is so incomparably the best way from almost any point of view from which one chooses to look at it, that the two systems cannot be named together. Both methods require careful management, but the returns under glass in the shape of crops are so much greater and more certain, as to drive, as I have said, all comparison out of the question. Where in England, in a general way, can you ripen and crop Peach and Nectarine shoots from 3 feet to 5 feet long annually in the open air, or where can you produce trees from 12 feet to 20 feet in diameter in two years with crops of ten and twenty dozens, more or less, in the same time? The answer is, Nowhere. While the cultivator outdoors is fighting with blight, frosts, mildew, and cold seasons, and waiting sometimes years for his first crop, the underglass man is away far ahead of him. Over-building Peach houses, forsooth! There is only one complaint on that head I ever heard of, and that is, that the supply of Peaches exceeds the demand and makes them too cheap in the market for the grower. Next, says Mr. Gilbert, "Nobody can grow Melons now in manure frames because they have houses." Why should they attempt it? Hot-water pipes are cheaper and far better in every way, as has been proved by overwhelming testimony. Lumbering stage coaches have gone out of fashion because railway trains are a thousand times better, and who regrets the change? Here is a debtor-and-creditor account of the old manure-bed system of growing Melons compared with pits heated by hot water, and as Mr. Gilbert understands both as well as I do, let him disprove my statements if he can. Our Melon pits, heated by hot water top and bottom, and which have been worked most successfully these 22 years back, are 25 yards long, and all that is needed to set them in operation in spring is to turn a valve. Previously, the same amount of frames 6 feet wide would have required a heap of litter and leaves at least 26 yards long, 3 yards wide, and 5 feet deep at the beginning, as all such hot-beds sink down 70 per cent. before the season is over. Such a hot-bed would have required at least fifty loads of leaves and litter, all of which would have had to be first collected in the woods and afterwards carted, and prepared for several weeks previous to putting up, not to mention linings later on and other attention in the way of protection. And this work would have to be repeated annually in all such

cases, the mere cost of which alone for two years would build a Melon house completely heated. Horse labour at the rate of 10s. per day is one of the heaviest items of garden expenditure. And this takes no account of the uncertainty of crops in the manure frames, for, say as one likes, they are uncertain compared with hot-water pits, in which the crops are generally both heavy and good. Of course, in small places where the materials are readily procurable and there are no hot-water pits, manure frames are useful, and I have not a word to say against them, but wherever Melons are in regular demand in quantity, the less such pits are used the better for both employer and gardener.—J. S. W.

—Mr. Gilbert's progress is in the wrong direction when he advocates the culture of Peaches on walls instead of under glass, and Melons in frames instead of in houses. Wall culture of Peach trees is not now so popular as it used to be, because superior fruit can be obtained from houses, and, as some allege, at less expense. As for Melon culture, Mr. Gilbert does not practise what he preaches, for some of the best crops of Melons I have ever seen were cultivated in houses at Burghley. In cases in which Peach houses can be afforded, walls facing the south or south-west could be better utilised if planted with the finer varieties of late Pears—such as would come in during February and March—than with Peaches. That excellent Peaches can be grown on open walls there is no doubt whatever, but success cannot be attained without considerable expense; and when the best has been done for them, the crop is neither so certain nor so good as that which can be obtained from an orchard house or an ordinary Peach house, where the trees are planted out and trained to the roof-glass. The finest wall Peaches—such as Noblesse and Royal George—I have ever seen were gathered north of the Tweed. The walls were about 14 feet high and built of red bricks. There was one house for early Peaches, but the entire late crop was gathered out of doors. The border in which the trees were planted had been well made and drained. The soil ought to be of a character to promote the formation of a large mass of fibrous roots, and they should be encouraged to grow most freely near the surface. With wall trees out of doors my plan has been to make the ground moderately rich, and in planting to place a barrow-load of decayed turfy loam, broken up fine, amongst the roots. In this loam the trees accumulate a mass of roots the first year and make good growth; the next season they become much more vigorous, and if any of the leading shoots are likely to grow too strongly, pinch them back, an operation which causes them to make three or more shoots of a better kind; by this time the trees will be of large size and well furnished throughout with bearing wood. Every tree should be lifted again in autumn and replanted in the same kind of turfy loam, spreading the roots out to their full extent. As a rule, they will not require any more lifting and replanting, but if any of them should grow too vigorously, they may again be lifted and replanted. If this is done every second year, such a mass of fibrous roots is accumulated, that the mere lifting and immediate planting of the trees do not affect the blossoming and setting of the fruit, but sufficiently check the growth of the young wood for the season. Summer-pinchings, thinning-out, and nailing-in of the young wood are essential to the well ripening and colouring of the fruit. So, also, is keeping the leaves clean. Red spider, mildew, and the Peach aphid, if allowed a fair chance in the dog days, would ruin the best of prospects in a week.

Peach and Nectarine trees in pots come next. I have purchased maiden trees—that is, trees one year from the bud—potted them in November, and by careful pinching and training the year following, they have become handsome fruitful trees, which bore a crop of most excellent fruit the next year—that is, in the third season's growth from the bud. I carried off the first prize at the Crystal Palace with six fruits from one of these three-year-old trees against fifty-six competitors

for the best dish of Peaches: and I also gained the first prize with Nectarines from trees of the same age. I mention these matters in order that Mr. Gilbert and other practical men may guess what the quality of the fruit must have been that could take a first prize against fifty-six competitors in September. An orchard house full of well-grown trees from the time when the blossoms open in spring until the ripe fruit is gathered in autumn is a source of daily interest, and the labour attendant on cultivating the fruit to perfection is not so exacting as that of growing a collection of Auriculas or Carnations up to the highest degree of excellence. The trees, of course, require summer pinching and pruning, and the shoots have to be tied down in order to expose the fruits to the light, and this must also be done in the case of wall trees. A Peach house may be constructed in two divisions—one to be forced and the other for the production of late fruit. As in

at-home, matter-of-fact individual, and may not be well posted up on this subject; still I do think that I should have heard from the many visitors who call here in the course of a year some tidings of failure had such been the fact. At any rate, so far as the district for many miles round here is concerned, there is not an atom of truth in such a report. At this place our Peach and Nectarine trees are models of health and vigour, and they fruit, not a little, but heavily every year—indeed they never fail; and the fruit is hardly second either in appearance or quality to that produced by trees that have all the advantages of glass. In further justification of my opinion that open-air Peach cultivation is not failing, I would mention the magnificent trees at Strathfieldsaye, Bearwood, Somerley, Broadlands, and Dogmersfield. Is the wish father to the thought, *i. e.*, is outdoor cultivation too troublesome, or is it, as my friend Gilbert hints, an overplus of glass erec-

training suits it best. Plant healthy fan-trained trees, and let them spread out evenly in all directions. Keep them clean during the growing season, by dusting with tobacco powder or syringing with tobacco water, dipping the points of the young shoots into the mixture. Cover with nets to keep off birds so as to let the fruits get fully ripe. In winter cut out weakly and exhausted fruit-bearing wood, and nail in the young shoots of the preceding summer's growth full length, as the Morello bears the finest fruit on the young wood. Even in fruit-growing counties Morellos are always profitable.—J. G. H.

APPLE POMEROY.

ALTHOUGH this delicious old Apple has been obliterated from the leading nurserymen's lists, and the tree is rarely met with in a young state, it possesses qualities so peculiarly its own, that it would be a mistake to allow it to die out. Pomo-

Lambton Castle, from the south-west. (See p. 249.) Engraved for THE GARDEN from a photograph.

the case of out of doors fruit, the foundation of successful culture must be laid in well-constructed borders. We made our Peach borders on the same principle as the Vine borders. They were dug out 3 feet 6 inches deep. About 9 inches of brick-bats were placed in the bottom, and over these was laid the compost, consisting of decayed turf; a good sprinkling of mortar rubbish was mixed with it, and some crushed bones. There is a depth of 2 feet 9 inches of this material, and in it the trees have made grand growth, and also bear well.—J. DOUGLAS.

— I am at a loss to understand the meaning of various communications that have recently appeared in THE GARDEN as to the non-success of Peach growing out of doors. Is there, or has there been a general collapse of open-air Peach cultivation? My answer is, no. I am, I confess, a stay-

tions that makes people less attentive than they were wont to be to outdoor Peach trees, allowing them to get smothered with aphides early in the season, and then bewailing the climate and crying deterioration, when a thorough drenching of clear water would have annihilated the aphides and have been salvation to the trees. Prevention is better than cure, and this we practise; hence our trees do not get smothered with aphides.—W. WILDSMITH, *Hockfield, Hants.*

Morello Cherries for cottage walls.—Let me direct special attention to the value of the Morello Cherry for covering the walls of cottages, on which it hardly ever fails to produce good crops. The latter sell well owing to the fact that they come in after the glut of other fruits is over. This Cherry grows and fruits well on any aspect, and the simplest kind of

logists say there are several varieties of the Pomeroy—the early, the late, the new, the old, and the winter—but, provided young trees of each were planted side by side in the same soil, it is questionable if the Pomeroy of the western counties and that of the north, sometimes called the green Blenheim, would not embrace the whole family. One of our oldest Apples, and at one time a great favourite, aged trees of it are occasionally met with in all parts of England, but never, so far as I am aware, in any quantity; and so distinct is the fruit, with its rough covering of russet richly suffused under warm sunshine, that once seen, it can never be mistaken. At this place, although there may be more in the parish, I have only met with one tree in our orchards, and this is a hoary relic of the last generation. It generally bears a crop of fruit, fair specimens of which justify me in say,

ing it is the Pomeroy No. 1 figured in the "Herefordshire Pomona." There it is described as an early Apple, ripe in October, and in use through November and December. The editor was quite right in giving it this prefix, as I have had it fit for use in September. It is not, however a fleeting Apple, for, soft and tender though it be, it keeps well, apparently without undergoing any change, throughout the winter. This quality, it may be well to remark, does not appear to exist everywhere—a fact which leads me to think many of our fruit rooms are open to more than one improvement. Early and mid-season Apples, all admit, are too numerous, and men of progress are looking for varieties that will carry us well over Easter. Of these we have a few, but most of them are deficient in quality; and few care to eat an Apple in an uncooked state that is hard and acid. Others who appreciate the flavour of the Ribston and other crisp Apples cannot at any season eat them; consequently, they are obliged to seek flavour in fruit of softer texture. To this class of consumers the Pomeroy should prove valuable, for not only have I kept it for six months on a shelf in a cold fruit room, but I have always found it remarkably tender, with a peculiar delicacy of texture, juicy, sweet, and richly flavoured. It is not one of the Apples I should advise anyone to plant in quantity, but connoisseurs who appreciate these peculiar qualities should grow a few for their own eating.

W. COLEMAN.

SEASONABLE WORK AMONG FRUITS.

VINES.

THE principal work in early houses will be thinning the bunches and berries, stopping the shoots where the sub-laterals have filled their allotted space, and tying down as growth proceeds. The first part of this programme many people think should be deputed to a disinterested person, but this is a mistake, as no one knows better than the gardener in charge what his Vines are capable of doing. In all cases, be the Vines young or old, it is always well to err on the side of light or moderate cropping, as Grapes in these days must be perfect in colour and finish, otherwise they will barely pay for carriage to market. This point settled, the thinning of the berries should be pushed forward, as every day lost in the performance of this operation throws a useless strain upon the Vines. How to thin is another matter, as no two Vines of the same kind in different soils and under different treatment form their bunches and swell their berries exactly alike. The man in charge, as I have just remarked, should be the best judge, as one or two years' acquaintance will enable him to tell to a nicety what number of berries will go to the formation of a bunch that will neither be crowded nor straggling when ripe. When thinning is finished the inside borders should be mulched with well-worked horse manure or rotten manure, and watered to an extent that will ensure every particle of soil being thoroughly moistened. The general syringing of the Vines having been discontinued, all available surfaces should be well damped twice a day, the first time with clear, tepid water, the second after the house is closed with diluted liquid. If the Vines are weak, similar liquid, a pinch of guano, which makes foliage, or soot water may be advantageously used two or three times a week for filling up the evaporating pans, and a syringeful of the last, wherever it can be delivered without casting spray on the berries, will have an invigorating effect on the leaves and laterals. From this stage until the berries are stoned the laterals should be tied down where space remains uncovered, the strongest only being pinched, whilst those showing a tendency to weakness may be allowed to ramble, provided they do not reach the glass or impede a free circulation of air. The temperature in the Hamburg house may range from 60° at night with a little air, to 75° on dull days, 80° on bright days, and 5° higher after closing with solar heat. Night air should be shut off when the fires are stirred in the morning, and the ventilators stay remain closed until the rising temperature

touches 70°, when a gradual increase should set the maximum at 80°. Bearing in mind that the admission of air should never lower the temperature, the house at this changeable season should be closely watched, and so soon as the sun begins to lose power, reduction and final closing must be performed in time to run up a few degrees in the afternoon. Madresfield Court Muscat, Foster's Seedling, and Buckland Sweetwater do well under Hamburg treatment, but Muscats require a little more heat when they are setting. We sometimes find a Muscat Vine occupying the warmest end of the house, but in order to set and finish them properly early Muscats should always have a small compartment to themselves.

Succession houses being generally furnished with similar varieties, with perhaps Gros Colmar and a Frontignan thrown in, make good progress, and set their fruit well under identical condition as to heat, air, and moisture. The only difference I would suggest is more air on all favourable occasions, and perhaps a slightly increased temperature after closing. Gros Colmar, of which we have heard so much of late in a contemporary, is not the difficult Grape some writers who have recently achieved success would have us believe. The fact that it requires plenty of time not only to mature its fruit, but also to throw off its earthy flavour, has long been known by Grape growers generally, and those who have been most successful have invariably started their Vines early enough to give them the full benefit of the season and plenty of time for winter rest. Because it is a late-keeping Grape it is too often found in the Lady Downes house, perhaps the least suitable in the whole range of vineries, unless, as they ought to be, the Lady Downes are grown under Muscat treatment. Gros Colmar sets and swells well in a Hamburg house, but it should be sufficiently advanced by the end of July to ensure plenty of sun-heat and air for ripening the fruit and wood before fire-heat and diminished ventilation become imperative in the autumn. To secure these conditions, the secondinery, or a Gros Colmar house, should be devoted to its culture. When the berries of this Grape first become black they are unripe; when the leaves fall they are not at their best; but when they have been allowed to hang for a month on ripe wood, and another in a dry and rather warm Grape room, the quality of this by-no-means rich Grape becomes passable.

Late houses.—If Lady Downes and other late Vines are not already swelling their buds, the houses should be closed every day, with plenty of sun-heat and moisture, and the pipes may be warmed on dull days and cold nights. Water in a tepid state, as a matter of course, has been freely administered to the internal borders, and this may be repeated, as there is less danger of giving too much than too little water after this period, especially when it is borne in mind that the clouds this season have not contributed to the external roots their usual quantum. The syringe in this house plays a very important part, and where the canes are young they should have the benefit of fermenting material. Young rods of Lady Downes break well or uneven according to their state of ripeness. To ascertain whether they are properly matured one only need look at the last Grapes they produced, now hanging in the Grape room; if fresh and plump, the Vines will break freely; if black in the stalk and shrivelled in the berry, all long rods should be bent down over fermenting leaves until the back buds have started.

Late Muscats, especially the Bowood variety, are generally in advance of Lady Downes, and will now be moving freely. When well started, these and the late sorts in the adjoining house should be helped forward under precisely similar treatment.

Pot Vines now swelling their fruit will require plenty of stimulating food both in the way of top-dressing and liquid. The first can be replenished as often as the old is washed away, and the more frequently the second is varied the better the progress. Good liquid from the manure-heap is of course the standing dish in all matters horti-

cultural, but where this is flanked by guano, soot water, or some of the thousand and one kinds of highly concentrated artificial manures, members of the vegetable, like those of the animal, kingdom benefit by the change. When the Grapes are well through the stoning they may be pushed on apace, not by a high night temperature, which should be kept below 70° with a little air, but by closing early in the afternoon and running up with plenty of atmospheric moisture. If not overcropped and the roots have escaped into the bed, good laterals will require tying out in preference to pinching, as every leaf helps the fruit.

Cut-back Vines that have been shaken out and potted in 7-inch pots should soon be fit for the final shift into the fruiting size, which need not exceed 14 inches in diameter. Rough half-rotted turf, bone dust, and lime rubble make good compost, and as this will have to filter hundreds of gallons of liquid for the next fifteen months, animal manure should not be used. If dry it may be firmly rammed or pressed into the pots to prevent its holding much water in suspension; if warm also so much the better, as the tender roots, which must be slightly uncoiled, will not then feel the check. A bottom-heat of 75°, not too far from the glass in a light pit, is the best place for the newly potted Vines. Shade for a few hours on bright days may be necessary, and as water at first must be given sparingly atmospheric moisture will be found an invaluable sustaining agent until they can be freely exposed to air and light. This stage reached, ordinary vinery treatment will suffice.

Vines from eyes.—When the eyes have exhausted the stored-up sap they will make a dead stand, and as this is the critical period, bottom-heat must be maintained to favour their making roots. Being plunged in a moist bed slight shade and frequent dewing over with the syringe will render the baneful practice of watering unnecessary until the young roots touch the sides of the pots, and as these will quickly flush the dry-looking, elongated buds into miniature leaves and stems, the veriest tyro will know when to give water and reduce the shading. When in free growth the first shift into clean 5-inch pots must be made, and more room being needed a fresh sweet bed ranging about 80° should be ready for their reception. Here they must be treated as newly potted cuttings, and when re-established, more light, air, and water and less bottom-heat, by drawing them gradually to the surface of the bed will favour a firm, short-jointed growth of Vine.

FIGS.

When the fruit on early started trees show signs of moving, as now will soon be the case, more heat by day may be given to them, and the temperature may range about 65° on mild nights, always with a little air when the lights can be opened without sensibly lowering it. As days increase in length and the sun gains power large trees in pots or planted out in confined borders will take heavy supplies of water more or less enriched by stimulants, according to their vigour and the crop they are carrying. It is not, however, a good thing to over-feed, as strong liquid produces coarse unfruitful wood, whilst turf and old lime rubble or burnt earth produce a surface root run in which they revel without becoming gross. A word as to thinning here may not be out of place, as many people often thwart themselves by leaving all the fruit, no matter how thickly it may be set, to allow for dropping. At first sight this may appear sound practice, but the very fact of overloading, as I have often pointed out, is the straw that breaks the camel's back. If this erroneous notion could be got rid of, and Figs, like other fruits, were thinned at an early stage, this badly treated tree would soon redeem its character, and, comparatively speaking, under glass it would become a perpetual bearer. Although late, if not already done, heavily cropped trees may still be relieved by the removal of the least promising fruit, whilst those left should be well bathed twice a day and have all the sun and light that can be admitted.

Late houses, from which one crop only is expected, should now be tied in and ready for starting. If well watered and mulched the point buds will soon commence swelling, but unless fire heat is at command for falling back upon in bad weather, full air by day and a liberal supply should be admitted when nights are not frosty until the season is further advanced.

MELONS.

A good supply of fresh young plants must now be kept on hand for putting out as space occupied by winter Cucumbers becomes vacant. Where Melons are extensively grown it is a good plan to have a special nursing pit well worked with fire-heat and fermenting material combined, and to sow a few seeds once a fortnight. If not wanted the oldest batches should be thrown away, otherwise when pot-bound they soon become attacked by spider and rarely make satisfactory progress if planted out. Upon this principle a constant relay of sturdy young plants fit for house or frame is always at hand, and it is needless to say a good start with these soft-wooded tropical plants is more than half the battle. Early plants from which ripe fruit is expected early in May will now be well advanced, and once they have taken to the trellis will gather daily in strength. To maintain this it will be necessary to remove all male blossoms up to the time the female flowers are ready for

Fertilisation, when, provided the bottom-heat is kept at 80° and the air temperature proportionately high, there will be little difficulty in securing an abundant "set." This high temperature must not, however, be secured by keeping the ventilators closed, as Melons when setting or ripening are often injured by confinement in a moist atmosphere. On the other hand, they should have sufficient heat to maintain a circulation of fresh air, whilst root and atmospheric moisture during these processes should be slightly, but not injuriously, decreased. As soon as the fruit is safe, *i.e.*, the size of Walnuts, more water may be given, and gradually increased in quantity and quality until the Melons have attained their full size, when the second high and dry epoch will set in. When thinning the fruit it is very important that uniformity of size be well considered, and the better to secure this point the final thinning should not be made until after all the laterals are stopped and the Melons are large enough to require supports. For this purpose small pieces of board with wires attached to the corners, squares of galvanised wire netting, or bands of matting are used. I prefer the first, as the others, especially the last, sometimes leave marks upon the fruit when it is ripe.

Top-dressing.—When the young Melons commence swelling freely, and the soil recently kept dry has been properly moistened, the plants will be fit for the final earthing, if growing on hills; for top-dressing if in pots. For plants on hills a good covering of strong, friable loam made pervious to water with lime rubble will be found suitable; but plants in pots require the addition of bone dust, which suits them better than any other highly concentrated stimulant I have met with. Of this as much as will lie on a spade may be added to a good barrow-load of compost, and, provided it is thoroughly mixed a few days before it is wanted, slight fermentation will set in, when it will be fit for use. In either case the compost should be very firmly rammed with the potting rammer, as Melons rejoice in a solid, resisting soil that will not readily part with moisture. When the young roots have taken a firm hold of this, mild manurial stimulants answer best when supplied in a liquid form, as solid manure sometimes induces canker, and always encourages worms. From this time forward full exposure to sun and light, of which we have none too much, must be secured by keeping the glass clean and divesting the plants of laterals, but on no account must the main leaves be injured. Moisture can be created by damping the surface of the bed, the paths, and walls, but not the foliage before the house is

opened; and, provided the plants will stand it, they may be well syringed after it is closed in the afternoon. Some varieties will not, however, bear direct syringing at any time, and I question if the best flavoured fruit is not gathered from plants that never receive a drop of water over their leaves after the female flowers open. Spider is the worst enemy, but it rarely makes much headway when the plants are well grown with plenty of heat, fresh air on fine days, and an abundance of moisture.

W. C.

MARKET GARDENS.

FRUIT-GROWING FOR MARKET.

MR. GROOM is right in calling attention to the merits of the southern counties for fruit growing, but, as recently remarked in *THE GARDEN*, the English growers have not yet begun to compete with the Americans. They might do much more in the way of early Apples, as the American varieties do not arrive until later in the season. A good lesson might be learned from the Americans as regards the selection of sorts by growing only three or four of the varieties best suited to the locality. It is the mixed consignments sent into market by some of our home growers that give such small returns, when perhaps the same bulk of one variety would be worth double the money.

Conversing with a large grower a short time back, he informed me that he only grew five or six varieties. For the first crop he depends upon Early Julien, which is a heavy cropper, and can be marketed direct from the tree. Of Yellow Ingestre, sometimes called Summer Golden Pippin, he grows several acres. It is a great cropper, and, owing to its beautiful, clear primrose colour, sells well. On the same fruit farm Keswick Codlin is still grown in quantity, and Lord Derby, a large Apple, is a great favourite. The same may be said of Warner's King. A consignment of 3000 bushels of Wellington sent to the Borough Market realised 10s. per bushel. Mr. Charles Whitehead says, "An acre of woodland, whose underwood was never worth more than £7 or £8 per acre at twelve or fourteen years' growth, has yielded as much as £150 annually where grubbed and planted with Strawberries." Such facts as these ought to give some encouragement towards the production of good fruit, which must follow a judicious selection of varieties.

The soil is not so important as the varieties. Mr. Groom seems under the impression that the Kentish growers are favoured with the best of soil. This may be, but the fruit farm under notice, comprising more than 200 acres, was originally woodland covered with a poor growth of underwood, and many would have condemned the place at first sight. If soil is good, all kinds of fruit will succeed, but the geological formation often differs greatly over a small area. Chalk, with a thin surface layer of soil, is about the worst, but a fairly good soil mixed with the chalk will grow Cherries, Plums, and Red Currants. Round about Maidstone the soil overlies the Kentish ragstone, but very good Apples are grown. Apples and Pears also do well in the stony lands about Orpington. All through the weald of Kent the soil is very heavy, but good Apples are grown. Black Currants thrive admirably on the heaviest soil, provided the drainage is good.

The situation of the plantation is important; it is useless to plant on an exposed hill; while, on the other hand, if the plantation is in a valley or too near a stream, there will be great danger from spring frosts, as the mist will rise from such damp situations and settle on the flowers, a slight frost causing their destruction. If a little shelter is necessary, nothing is much better than Pampsons; they stand the wind well, and form a good screen, while the fruit will give a good return.

There is much truth in the remark made concerning English *v.* American Apples, that "the freehold system encourages fruit-tree planting." The English growers, if the land is not their own, have to bear many charges. The fruit farm before referred

to is an instance. Previously a poor woodland, it was taken in hand by the present cultivator, and at considerable expense made into a fruit garden. Then comes the extra tithe charge. It is like taxing a man for his industry. The grower remarked to me, "the land cannot bear three charges, and as the landlord has a right to his rent, while the labour must be paid for, the tithes must go unpaid."

A. HERRINGTON.

NOTES ON VEGETABLES.

BROCCOLI.—Whilst the commonly grown purple-sprouting Broccoli has stood so well, all white Broccoli has suffered severely; indeed, breadths of extra strong plants have been almost entirely destroyed by the recent hard weather. When later it is asked, why is it we import so much Broccoli or similar vegetables? let the reason be found in the nature of our winters, which play such havoc with green stuffs generally, and white Broccoli in particular. Could these be grown with safety, it is certain they would be grown abundantly. There ought to be an ample supply grown in the most southern districts for the London market; but it would even then be doubtful whether it would pay to send so far to such an abundantly stocked market as London usually is. I have found a few late-planted white Broccoli on poor soil to have stood exceedingly well; but they doubtless owe their immunity to the fact that they are not so robust as market plants must be if they are to be saleable.

PURPLE-SPROUTING, happily, is so hardy, that it almost always pulls through the roughest of winters. Its stems are well protected by its dense heads and side shoots, and there is not that tendency to gather moisture at the base of the shoots as is found in the broad, flat leaves of white Broccoli. The rule with market growers is to begin clearing off the purple-sprouting breadths quite early, much before all the sprouts have fully developed, and in this way a large amount of useless matter is sent into market, which would be better left at home. A large grower complained the other day that the condition of the roads in winter compelled him to keep quite three horses more than otherwise would be needful; but it is a fact that vans are sent into market day after day with loads of material, one-half of which is superfluous. If, instead of cutting sprouting Broccoli by the head, just trimming off a few of the roughest of the leaves, the edible portions of the sprouts only were taken off, packed neatly into baskets, and so loaded, what a very decreased bulk of matter would be sent into market. In the one case the green stuff is roughly handled, loaded, and exposed to all sorts of coarse usage; in the other the greens would go to the shopkeeper well preserved, fresh, and neat, and if sold per pound weight would findly pass to the consumer in excellent condition. But for sprouting Broccoli many fields would look barren indeed now.

WHITE TURNIPS, owing to drought which prevailed last autumn, have not been plentiful, and the severe frosts with snow seriously injured what bulbs were left in the open. For that reason we must not look for any considerable bulk of tops in the neighbourhood of London, but probably more remote districts will furnish a good quantity in due season. Some of the regular market growers purchase breadths of Turnip-tops in remote districts, and have them gathered and sent into the market in sacks in the spring. Ample employment is thus afforded for labour in that rural locality for a short time. Of course, the farmer still has the bulbs and rough leafage for manure, but the price given is not so considerable but that the question of turning in the entire green crop as manure is worthy of consideration. Having regard to the mild, tender, and pleasant quality and flavour of the tops of Swede Turnips, it is odd that breadths of these have not been grown specially for the London market, but possibly the bulbs can be more profitably utilised as cattle food. It is unfortunate that there should be such a prejudice against yellow Turnips, as these are more hardy than white ones, have richer flavour, and even produce tops less astringent in taste and much more pleasant eating. We seem in the yellow

Turnips to obtain some of that pleasant quality which has served to make Swede tops so acceptable.

A. D.

PROPAGATING.

DOUBLE PRIMULAS.—Unlike the single-flowered varieties of the Chinese Primula which are raised from seed, the double kinds are increased by layering, cuttings, or division, and where the plants have been flowering throughout the winter they will by this time in many cases lose their freshness, and may then be taken in hand for the purpose of obtaining a stock for next season, as the earlier in the year they are struck, so much longer will be the time to grow them into flowering plants. As propagation by cuttings is, unless carried out by one well versed in such matters, not always successful, layering is a mode of increase that commends itself to those who have not propagating cases and other appliances at hand, though by means of cuttings a greater number of plants can be obtained than from layers, as many shoots will form a cutting that cannot from their position be brought in contact with the soil unless separated from the parent plant. When the stock is to be increased by layers the plants must be thoroughly cleared of all old flower-spikes, dead leaves, and decaying matter, and the branch selected severed half way through with the knife, bringing it up in an upward direction, thus forming a sort of tongue from which the roots will spring. Generally speaking, the plants may be layered in the same pots in which they have grown, and when the above-mentioned directions have been carried out, the branches may be bent down as far as can be done with safety, and secured in position by a peg or pegs. Meanwhile, some turfy pieces of good open loam having been broken into lumps about the size of a Walnut, are packed around the stem, so that a plant when layered will have all the branches at its base embedded in this new soil, which being rather fibrous will ensure a good cluster of roots when the plants are struck sufficiently to be divided. After layering, the plants may be placed either in the greenhouse or in a frame, but after potting off they must be kept close till root action is restored. Increase by division is but a form of the above, as some plants will be potted at such a depth that the lower part of the branches is embedded in the soil, and when such happens they form roots on their own account, and all that is necessary to increase them is careful division. Any that are reasonably expected to have the different branches rooted should be turned out of their pots, and the soil removed very carefully, so as if possible not to injure a single fibre. Then with a sharp knife division is effected, the principal point being to leave a few roots on each part into which the original plant is split up. If the plants are flowering sufficiently to prevent their being divided, any time during the next month will suffice for the purpose, and where it is intended to propagate them by means of cuttings, a few weeks later will be a better time than now for that operation. A method I have followed with great success in striking cuttings is about this time to take the old plants in hand, and give them a thorough cleaning, then place them in a structure where the temperature is higher and the house closer than that in which they have been wintered. The result will be that in the more humid atmosphere the exposed portions of the old rugged stems all show a tendency to push forth roots, and when they are perceptible the whole plant may be cut up. In doing this, the roots at the base should be left on wherever possible, but by far the greatest number will have no roots of their own, unless it be those just on the point of pushing forth from the stem. The cuttings should, if it can be so arranged, have a couple of inches of old stem below the foliage, and any decaying leaves may then be removed. Small pots are by far the best for the reception of the cuttings, and they must be firmly secured therein, as the roots are very brittle. For this reason each cutting should be tied to a small stick, and when this is done it may be watered,

and after being allowed to drain for a short time, placed in a close propagating case in a structure kept at an intermediate temperature. If there is a slight bottom heat it is better to stand the pots on the surface for a week or ten days, and after that plunge them a little, in order that the additional stimulus may accelerate the formation of roots. The plants must not be kept too close, as decay is greatly to be guarded against, and on that account the lights should be removed every morning, and if condensed moisture is visible on the foliage tilted for a longer period. At the same time if possible the cuttings must not be allowed to flag, but even that is better than too much moisture. The soil best suited for the propagation of these Primulas is loam, peat or leaf-mould, and silver sand, the whole being sifted through a sieve with a quarter of an inch mesh. Besides this the top of each pot must be covered with pure silver sand, and a little of it sprinkled around the base of the cutting during insertion.

GRAFTING of the various fruit trees will now be in progress, or close at hand, and while this is an operation that does not need the delicate manipulation of some that are carried out under glass, yet attention to a few simple rules will be well repaid by the future measure of success. In the case of large trees with a head of branches that, owing to inferior fruit or some other causes, it is desired to graft with another kind, the head must be shortened in during the winter, and the scions intended for grafting taken and laid in by their heels in a cool spot, so that they will remain in a dormant condition longer than the stocks, as those latter should be just bursting into growth while the scions are in a dormant state. Crown-grafting is the method generally employed for large branches, as several grafts can, if necessary, be put on one branch, and the whole operation is very simple. The scions must be formed of the preceding season's growth, choosing such as are clean and well ripened. When required they are taken from the ground and prepared by making a sloping cut some 3 inches or 4 inches long, beginning opposite a bud and gradually sloping to the point. Just where the knife first enters a kind of shoulder must be formed, which will rest on the wood of the stock and assist in holding all secure. In inserting the graft it will be generally necessary to make a longitudinal incision in the bark of the stock, extending far enough to allow the graft to be pushed into its place. In the event of two or more grafts being put on one branch, a single cut in the bark of the stock will often allow sufficient space for all the scions, and of course they are held more securely than if the bark was cut at each point of insertion. This method is generally employed for the renovation of Apple trees, but the same, or at all events a slight, modification of it is available for many other fruit trees. The great point in all grafting is to ensure as complete a union as possible, and this being done the scion must be tied securely in position. After that the point of union must be made perfectly air-tight by means of good tenacious clay, mixed with cow manure, that has been moistened just sufficiently to render it pliable. This coating of clay will need examination from time to time to guard against cracking, and if this has taken place the defect must be at once made good, otherwise the grafts are liable to shrivel up. In the case of trees that are headed back in order to be grafted, some of the minor sprays should be allowed to remain on so as to keep up a complete circulation of the sap, and when the grafts grow and these shoots have discharged their functions they may be removed.

BOMAREAS.—These beautiful climbing plants, which have attracted a considerable amount of attention within the last few years, do not admit of any rapid modes of increase, unless seeds are obtainable, for although division may in a few cases be possible, it is an operation that requires considerable care, and some kinds very rarely push up a separate crown. Occasionally, where a plant has been confined in rather a small pot, so

that its vigour is considerably curtailed, it will divide into a couple of plants, which may be separated and potted singly. I have tried increasing the large-growing Bomarea (Arderi by means of the tubers that are attached to the roots, but though they remained perfectly sound for a very long time, none of them ever gave the least indications of starting into growth. The present season is the best time of the year for dividing any that are available for the purpose, and it should be carried out as carefully as possible, while the plants had better be kept rather close, and shaded for a few days, till root action recommences. When seeds are obtainable they should be sown in well-drained pots of good open soil, and must not be covered too deeply; care, too, must be taken not to over-water, otherwise many will perish, while, on the other hand, if they get very dry the loss amongst them will be as great. Not only is this caution necessary in the case of Bomareas, but in that of many other plants, for should the seeds at any time be subjected to extremes either of dryness or moisture, they will, in all probability, lose their vitality. T.

GARDEN FLORA.

PLATE 588.

IMPATIENS HAWKERI.*

REPRESENTATIVES of the genus *Impatiens* (of which the common greenhouse annual Balsam, *Impatiens balsamina*, is the best known) are widely scattered over the western as well as the eastern hemisphere, one or two species being found in Europe. Amongst the kinds best deserving of cultivation may be named *I. Jerdoniae*, a dwarf-habited species that was introduced from the Neilgherries over thirty years ago, but which, notwithstanding the length of time that has elapsed since it came into cultivation, and the distinct and beautiful character of its flowers, is not so well known or so often met with as it deserves to be. The deservedly popular *I. Sultani*, that made its appearance a few years back from Zanzibar, is too well known to require any notice further than saying that the high opinion formed of the plant when first it came out has not only been verified, but has increased as its cultural requirements have become better understood.

The subject of the accompanying plate, *I. Hawkeri*, is most like *I. Sultani* in the character of its growth, and in the form and appearance of its flowers, but it is a much finer plant. The ground colour of the flowers, which is dark carmine, is intensified by a conspicuous white eye, around which is a peculiar shade of bluish violet that gives to the whole an appearance that is not easy to describe. As will be seen, the flowers spring from the axils of the leaves, and are produced in continuous succession so long as the plant makes growth, which may be set down as from the beginning of spring to the end of autumn. For the decoration of a warm house its merits cannot well be over-rated.

Its cultivation is simple; cuttings consisting of two or three joints of the shoots root readily in sand in a warm house, but from the succulent nature of the stems and leaves they must not be confined too closely, or kept wetter than is found necessary to prevent flagging, otherwise they will damp off. A compost consisting of moderately open soil enriched with a little rotten manure and leaf-mould, and some sand, will answer for it. It comes from the South Sea Islands, and consequently will require to be grown in a warm house or pit, though cooler quarters may answer for it in summer. One of the principal matters to be kept in view in the cultivation of this and other soft-wooded quick-growing plants

* DRAWN FOR THE GARDEN by MR. MOON IN MR. BULL'S nursery, August 19, 1886, and printed by G. Severeys.

MIATHEM HAWKEE

is that they must be stood well up to the glass in light houses or pits, without which the shoots are drawn out long and weak, in which case half the beauty and pleasing appearance of the plants is lost. T. B.

STOVE AND GREENHOUSE.

T. BAINES.

GREENHOUSE RHODODENDRONS.

THERE is no race of hard-wooded flowering plants with which so much has been effected in recent times as in the varieties of greenhouse Rhododendron that have resulted from crossing some of the species that have been introduced. Amongst the various species possessing more or less merit from a cultural point of view may be named *R. Gibsoni*, a white-flowered kind with which most people who take an interest in gardening matters are acquainted. It was introduced about fifty years ago, and as it got plentiful was usually to be met with amongst collections of Azaleas, which to the casual observer the plant is not unlike in the character of its growth, as well as the appearance of its flowers, which generally come in pairs, although the habit is somewhat more erect, and the wood stronger than in the present race of Azaleas. A well-grown example of this Rhododendron when well furnished with flowers is a beautiful object, yet, somehow or other, it seems to be falling so far out of favour with most plant growers, that it is not unlikely to soon be numbered amongst desirable things that are all but lost to cultivation.

Amongst the largest growing representatives of the genus *R. Nuttalli* stands at the head. It is a magnificent species that bears white yellow-shaded flowers, and attains the dimensions of a small tree, but in habit the plant is somewhat spare; still, where there happens to be a structure large enough to allow its being turned out in a bed so as to admit of the plant showing its true character, it has a noble appearance. It comes from Bhotan. The plant is seldom met with, as the size to which it attains precludes the generality of those who grow plants under glass from attempting its cultivation.

R. DALHOUSIEI is another fine species, bearing large white flowers. It comes from the Himalayas, a country that has given us numbers of fine plants. Why this grand species has not come more into cultivation it is not easy to say, as it does not attain an unmanageable size. There are numbers of other kinds introduced from various countries which succeed under greenhouse treatment, or even with the protection afforded by an unheated house, for which latter description of structure many of the Rhododendrons in question are suitable subjects. It is about forty years since the fine and distinct *R. javanicum* was introduced, which has played such an important part in giving us the numerous beautiful hybrids now in cultivation. There are two forms of *R. javanicum*, one with pale yellow or buff-coloured flowers; the other with flowers of a deeper shade of yellow, and lightly suffused with salmon. Both forms are inclined to an erect, spare habit of growth, especially whilst the plants are young; this disposition shows itself to some extent in many of the varieties that have the blood of *R. javanicum* in them, although the more bushy habit of such kinds as the Malacca species, *R. jasminiflorum*, where used in the cross, has gone far to correct this straggling habit. Examples of the earliest raised varieties that have attained a size of several feet in diameter, and as much in height, may now be met with; these, when in bloom, are very valuable in the conservatory and greenhouse, and prove the enduring character of the plants, which evidently are not impatient of a little occasional inattention, such as would be of serious consequence to many kinds of hard-wooded subjects. This ability to keep on in a healthy condition for a lengthened period is exemplified in *R. Gibsoni*—already noticed—as some of the plants that were first raised are yet in existence, and are still

healthy and vigorous, and bloom profusely every year. One of the features which these hybrid Rhododendrons possess is the unusual range of colour present in them, which even exceeds that of the now numberless varieties of greenhouse Azaleas. The varieties of this section of Rhododendron embrace every shade from pure white and sulphur to pale and deep yellow, pink and red to the deepest crimson.

The usual method of propagation is by grafting, which is easily effected when the plants are kept in a genial growing temperature. But in private gardens the stocks whereon to graft are not often available, and although grafting presents the advantage of getting the plants on quicker, and also of each single joint of wood making a plant, still there is not much doubt but that these Rhododendrons would strike readily from cuttings of half or three parts ripened shoots if taken off at a joint and inserted singly in pots filled with sand, kept close and moist in a cool house until the base of the cutting is callused, then moving them to where they will receive a moderate amount of heat. So treated they would soon form roots and push top growth, after which they should be potted in peat to which a little sand is added. In fact, soil similar to that which Azaleas require answers for them in every way. Although nothing more than a greenhouse temperature is required to grow them, still with a view to getting the plants up to a useful size as quickly as possible it is well to keep them in an intermediate temperature for a year or two.

Young plants show little disposition to produce lateral shoots; consequently stopping must be resorted to, or bending the point of the leading shoot down in a horizontal position will answer the same purpose by causing the buds in the lower joints to break. It is important that this should be attended to early enough before the plants have had time to become leggy, otherwise the single shoot of which the young plants will most likely consist will require to be cut back, which obviously will be so much time wasted. Sufficient attention to this, by stopping or bending down any shoots that show an inclination to take an undue lead, is necessary until the plants have attained some size and are sufficiently furnished, after which they usually require little further attention in this way. Like most plants that are long-lived, the progress these hybrid Rhododendrons make in the early stages of their existence is somewhat slow, alike in the formation of roots as in top-growth; consequently care must be taken not to over-pot them, although ultimately, as they attain size and age, it is requisite to give large pots, otherwise the growth becomes weak. After they have been grown for something like two years under glass, they will be better stood out of doors during summer, but in thus exposing them in the open air care must be taken to protect the roots from the drying influence of the sun and wind, which, if allowed to act directly on the pots, will cause much harm. To prevent this, the pots should be plunged in coal ashes, or have some sort of material, such as a piece of mat, tied round each, looking frequently over them to see that they do not want for water. When well managed many of the varieties produce flowers two or three times in the course of the year from successional growth which the plants when in a vigorous condition make. T. B.

Cyclamens.—The favourite spring flowers may now be seen in great beauty at most of the nurseries, in which a specialty is made of them, in the neighbourhood of London. Mr. Walker, Whitton, who devotes great attention to the above, has, at the present time, a very fine display, the colours ranging from pure white to very dark purple. The plants are very dwarf, and show off to great advantage their wealth of bloom.

Steaming or smoking plant houses.—The system of destroying insects in plant houses by steam from tobacco water is, as yet, but little practised. Its merits are, however, well tested by plant growers, who report favourably in reference to

it. Mr. Williams, of Holloway, who has practised it for some time, states that its merit consists in the ease with which it destroys green fly upon flowering plants, and without damaging them. Amongst plants subjected to it were many Orchids, and some others, which invariably suffer from the fumes of tobacco-smoke. These were quite uninjured by the steam; even the half-developed fronds of tender Ferns were unscathed. Mr. Wolford, gardener to Mr. Lee, of Leatherhead, has also tried it, both upon flowers and plants, and reports favourably of this kind of insecticide, which promises to be a boon to plant growers. —G.

Phyllanthus submarginatus.—Some kinds of *Phyllanthus* are well-known stove shrubs, but this appears to be far from common, though it is worthy to be ranked with many of the others. This plant will, if stopped once or twice when young, form a neat-growing bush with slender branches, the upper portions of which arch over in a very graceful and pleasing manner. The minor branchlets are also of a pendulous character, and are regularly furnished with small, roundish leaves of a pale green tint. From the slender branches, neat foliage, and general contour of the specimen it is well adapted for use as a table plant, or for any other position where a subject of this class is required. It may be grown in the cool end of the stove, or even in the temperature of an intermediate house, as, if required for indoor decoration, the cooler it is grown the longer will it stand in a room. Cuttings of this *Phyllanthus* strike root readily during the spring and summer months, and it is in no way particular as to soil. —T.

Hebeclinium ianthinum.—Among bold, free-growing, free-flowering subjects suitable for the embellishment of the conservatory during the spring months must be included this plant. This is a near ally of the *Eupatorium*, which it closely resembles in many particulars. Perhaps an enlarged *Ageratum* would convey a better idea of its general appearance, for, in colour as well as in other particulars, it closely resembles some of the members of this genus, but flowers now instead of during the summer months. Another species, viz., *Hebeclinium atrorubens*, which flowers later, is in some particulars superior to *Hebeclinium ianthinum*. In *Hebeclinium atrorubens* the leaves are larger, and have the midribs as well as the leaf-stalks and young shoots densely covered with dark-coloured hairs, which extend even to the exterior of the calyx. They are plants of the easiest culture, as they root in a few days and grow very freely. They should be grown during the summer in company with, and under the same conditions as, *Salvias*, *Eupatoriums*, and similar subjects. Care must be taken that during the hot weather they do not suffer from want of water, as the foliage once discoloured seldom regains its freshness. —ALPHA.

Chorozema cordatum splendens.—Trained at the end of a greenhouse so as to form a screen, this *Chorozema* is now profusely laden with its bright-coloured, pea-shaped blossoms. At the same time its value is greatly enhanced by the fact that grown in small pots in the shape of little bushes it is equally floriferous, and for this reason a place may be often found for it where its rambling habit would be inadmissible. This is one of the most vigorous growing of the *Chorozemas*, and at the same time as showy as any, a good companion to it in its shrubby form being the yellow-flowered *Chorozema flavum*. It is a plant by no means fastidious in its requirements, doing well in good fibrous peat with an admixture of turfy loam and sand, this latter being very essential. Cuttings of this *Chorozema* strike root fairly well if taken during the summer just as the current season's growth commences to acquire a woody texture, and dibbled into pots of sandy peat pressed down very firmly. The whole must be covered with a bell-glass and kept in a greenhouse temperature for a time, when a little additional heat will hasten the formation of roots. To get bushy little plants they must have the points of the shoots pinched out when young, but when large enough to bloom if cut back after flowering the following season's display is often considerably curtailed, for though the plants grow freely they seldom flower so well as if the long shoots are tied in rather than cut off. When grown in a position, such as the end of a greenhouse, it is

rather liable to be infested by red spider, which soon causes the foliage to acquire a sickly hue and permanently injure the plant. To prevent this it must be well syringed during the hot weather, and in the case of plants in pots they may with advantage be placed out of doors during the summer in order to mature their growth.—H. P.

Gesnera macrantha.—Several of the Gesneras, in addition to *G. cinnabarina* alluded to in THE GARDEN (p. 185), are well worthy of notice, and of these one that has been for some time and still remains very showy is *Gesnera macrantha*, the prominent feature of which is the bright coloured blossoms, as the foliage is by no means richly tinted. It is a tuberous-rooted species that has a season of growth, then flowers, and after that gradually goes to rest to start again later on. Such being the case, it is evident that the time of flowering will depend to a great extent upon the duration of the period of rest, but if allowed to follow its natural inclination it will commence to grow some little time before Christmas, and flower during the first three months of the year. The blooms are of a bright vermilion tint, and during the dull days of winter are very conspicuous. The cultivation of this *Gesnera* is easy enough; all that is required is to pot the tubers in good open, fairly rich soil, and gradually water as they start into growth. They should not be syringed very frequently, as too much wet is liable to injure the leaves, owing to the hairs with which they are covered.—T.

Erica melanthera.—This is about the least fastidious of all the greenhouse *Ericas*, and may readily be grown wherever there is a structure with sufficient heat to keep out the frost. It is a dense, much-branched kind, and flowers throughout the early months of the year, some specimens here being now in full bloom. The individual blossoms are but small, yet they are borne in such profusion that the whole plant is quite covered with them, and in that state they exhale a rather singular, but to many agreeable, perfume. Their colour is whitish, against which the black anthers stand out very conspicuous. This *Erica* is far less liable to mildew than most of the others, so that it can be often wintered successfully in a cold frame where most other kinds would perish from damp. It is very useful for cutting purposes, as the blooms can be used in many of the smaller arrangements of cut flowers, and last a long time in a cut state. Added to this, even if severely mutilated, it will break freely into growth and flower profusely the following season. Shoots that are produced when the plant is cut back but moderately are more likely to strike if taken as cuttings than those borne on plants more severely reduced, as in the case of these latter the shoots are more succulent, and thereby additionally liable to decay.—H. P.

Camellia house.—This is now very gay, and the flowers are most useful when a lot of cut bloom is required. We find the old French White to be one of the best for cutting. It is less formal than many of the doubles, stands well, and its many shades of colour add greatly to its usefulness. It is a profuse and consistent bloomer. *Fimbriata* and *Lady Hume's Blush* are also just now a mass of flower, but, beautiful as the individual blooms are, they cannot be used for vases like the French White; their chief value is for bouquets, wreaths, crosses, &c. A very old variety, in shape like *Donckelaari*, but pure white with tiny markings, is also worthy of note. It is a pretty and attractive flower, and its partially expanded blooms work up nicely with the French White. *Donckelaari* in all its varied markings is also useful in the same way, as it also lacks the formality of many of the newer varieties. *Woodsii*, an old and little-known variety, of a deep, rich rose colour, is used where this particular colour is required; and other serviceable varieties are *Bealli*, *eximia*, *Chandleri*, and *conspicua*. As will be seen from the above list, our varieties are of the oldest, but from the reasons already given they are more useful than newer sorts, for, highly ornamental as these are, their very stiff, formal flowers are of little use for cut purposes. A great deal has been written of late on the dropping of *Camellia* buds: this is a state of things practically unknown to us. Our beds are thoroughly well drained and a perfect mass of roots; therefore it is

not easy to over-water them except just in the dead of winter, and any loss of bud would under these circumstances arise from drought. Given careful planting at the outset, with plenty of drainage, I do not know a flower that, when it is once well established, will give, year after year, such a continuous supply of flower with so little trouble and expense. The labour bestowed on the *Camellia* house is trifling. Disbudding, an occasional fumigation, and the least bit of fire in very sharp weather, and in summer abundant ventilation with some heavy syringing at intervals, enable us to have an abundant supply of bloom from Christmas until the latter end of May. Very little in the way of stimulants is required to keep them floriferous and in vigorous health. So far as our plants are concerned, all they get in this way is a liberal top-dressing of cow manure just as the young growth is beginning to move. This remains on the beds all through the year, and serves, after all the strength has been washed out, as a good mulching.—E. B.

Hibiscus schizopetalus.—Four years ago I purchased a plant of this from a nurseryman, and it bloomed a few months after it reached me. I have struck some cuttings from it, but I cannot induce either the old or the young plants to bloom. The latter are perfectly healthy. They are about 2 feet high, in 5-inch pots, and in a soil consisting of peat and sand, tightly potted, and kept in a small stove-house, the average heat of which is about 70°. What treatment differing from my own can I adopt to induce these beautiful plants to produce blooms?—J. B., *North Devon*.

* * The cause of failure is most likely want of pot-room and manurial stimulants during the growing season. Unless the plants after the first year have pot-room proportionate to the growth natural for them to make, they linger on, producing shoots not strong enough to bloom. By annually cutting the shoots in moderately and partially removing the soil, replacing the old exhausted material with new, that is well enriched, and by liquid stimulants given regularly whilst active growth is going on, the plants may be kept in a flowering condition for a time with their roots somewhat restricted. Still, even thus treated, they must have larger pots than would suffice for most things. The young plants, now 2 feet high in 5-inch pots, if bushy in proportion to their height, should have had pots much larger. Even when planted out in a good-sized border they must have rich top-dressings, and manurial stimulants as well, in the growing season, or the plants soon get too poor to flower. I should recommend their being treated more liberally in this direction, shortening the branches in each spring so as to keep some proportion between the top-growth and that of the roots.—T. B.

North aspect for glass houses.—We are so accustomed to value south aspects for glass houses, that we hardly realise how valuable the opposite is until the need for utilising it arrives. When only the forcing of plants or fruits is concerned there can be no question about the value of direct sunlight. But there is the question of retarding as well as of forcing, and during the last few years the former has assumed much greater importance than it used to do. I need only refer to the value of late *Chrysanthemums* as compared with early ones as an instance of the advantage of retarding, and there can be no doubt but that a glass house with a north aspect is much more easily kept at an equable temperature than a south one, even if temporarily shaded, and at all times of the year where flowering plants are largely grown the north house is one of the most useful. At this season when bulbs and the host of other early flowering plants are being forced into bloom, it is necessary to gradually inure the plants to cooler quarters before they can withstand the cold draughts and dry atmosphere of drawing rooms, and a north house offers just the conditions necessary, and if glazed with Hartley's plate glass, a subdued light and equable temperature will be obtained nearly all the year, and the flowering season of many plants greatly prolonged.—J. G., *Hants*.

Pelargonium (zonal) Dr. Orton.—This beautiful variety is alike useful for winter flowering and also the decoration of the flower beds. In habit

it is very dwarf and compact, remarkably free-flowering, the trusses and individual flowers large and of fine form, and very dark scarlet. We have seen it bedded out during several seasons, and its bright colour was very pronounced amongst all the other varieties.

AMHERSTIA NOBILIS.

THE following account of the discovery of the *Amherstia* in Burmah will doubtless be interesting to many: The first notice of this beautiful tree is to be found in Wallich's "*Plantae Asiaticae Rariores*," published in 1830, in which work it forms the subject of the first plate. It was named by him after the Countess Amherst and her daughter, Lady Sarah Amherst. He was first told of its existence by Mr. Crawford, who brought him a leaf and dried specimen of the flower in 1826. In March of the following year Mr. Wallich saw himself the trees noticed by Mr. Crawford, and gives the following account of his meeting with them: "In about an hour I came to a decayed *kioum* (a sort of monastery) close to the large hill of Kogun, distant about two miles from the right bank of the river (Saluen) and twenty-seven from the town of Martaban. . . . There were two specimens of this tree here; the largest about 40 feet high, with a girth at 3 feet above the base of 6 feet, stood close to the cave; the other was smaller, and overhung an old square reservoir of water lined with bricks and stones. They were profusely ornamented with pendulous racemes of large vermilion-coloured blossoms, forming superb objects unequalled in the flora of the East Indies, and, I presume, not surpassed in magnificence and elegance in any part of the world. I call this tree *Amherstia nobilis*. The Burmese name is *Tboka*. Neither the people here nor at Martaban could give me any distinct account of its native place of growth; but there is little doubt that it belongs to the forests of this province. The ground was strewn, even at a distance, with its blossoms, which are carried daily as offerings to the images in the adjoining caves. . . . There can be no question that this tree when in full foliage and blossom is the most strikingly superb object which can possibly be imagined." The first specimen was brought to England for the Duke of Devonshire in 1837, and flowered in the stove at Chatsworth some years later. But the first plant to flower in England was one which belonged to Mrs. Lawrence, of Ealing Park, Middlesex. It was then only 11 feet high. This plant was afterwards presented to the Royal Gardens, Kew, where it continued flowering for a few years, but, on growing too large for the Fern house, it was removed to the Palm house, where, not having sufficient moisture or heat, it pined and died. The specimen now in flower at Diddington Hall, Norfolk, was presented to Mr. Tyssen Amherst by Sir Joseph Hooker in 1882 when it was only 18 inches high. It was placed in a Cucumber house, where it did not thrive well. Last spring it was removed to a stove specially arranged for it, where it grew rapidly and is now a well-furnished tree 9 feet 6 inches high, and 11 feet 6 inches across the branches. It has at present six flowers with from fifteen to eighteen blossoms on each. It is kept in a temperature between 70° and 80°, and excessively moist. Not only are the flowers of this tree quite lovely, but its long dark foliage and drooping growth form a most beautiful object, which well repays all the trouble and care bestowed upon it.

SHORT NOTES.—STOVE AND GREENHOUSE.

Habrothamnus elegans in fruit.—The berries of this favourite greenhouse plant, which are but little regarded, are equally as attractive as the flowers. When the specimen is planted out and favourably situated they are borne freely in large bunches, and during winter and spring are seen at their best. They are nearly as large as a small grape, and of a rich rosy crimson colour. So continuously does the plant bloom, that clusters of flowers as well as bunches of ripe fruit are often to be seen at the same time.—T.

Imantophyllum flowers.—We keep our *Imantophyllums* for the most part in a greenhouse, but directly the flower-spikes are visible they are removed to a warmer structure. If this is neglected the flowers are not nearly so fine, as the lower temperature seems to prevent them from attaining full development, though the plants kept therein are in robust health. I have also wintered them successfully in

a cold frame whence frost was just excluded, but in that case they must be quite dry, otherwise many of them will rot.—T.

Clematis indivisa.—This New Zealand species of Clematis should be grown by anyone requiring a free-growing greenhouse climber to flower throughout the spring months. If allowed to grow at will, the branches dispose themselves in graceful festoons, and are now quite laden with their pure white starry blossoms. The principal things to guard against in the case of this Clematis are aphides, which often make their appearance on the young shoots, and quickly cripple them unless removed. If the atmosphere of the house is rather stagnant during the winter months, the foliage is liable to be attacked by mildew, which soon disfigures it. A good circulation of air is the best preventive, and should any signs of mildew be seen, this, combined with a good dusting of sulphur, will generally effect a cure. This Clematis may be increased by cuttings of the half ripened shoots, treated in the same way as many other greenhouse subjects, but a quicker method and one that is usually followed in nurseries is to graft a young shoot on a portion of the root of the Traveller's Joy, in the same way as the many garden varieties of Clematis are increased. As the point of union is below the surface of the soil the scion will after a time form roots of its own, and is thus rendered independent of the stock.—H. P.

Hybrid Amaryllids.—In reply to Mr. H. Nehrling (p. 236), I may say that I have devoted much attention to intercrossing Amaryllids. I have tried to effect a cross between Crinum and Hippeastrum (being tempted to do so by successes with other apparently impossible parentages), but never succeeded; nor had I better results when I tried Amaryllis reticulata, which, having oval, wingless seeds more nearly in form approaching the bulb-like seeds of Crinum, promised a better chance. I found A. reticulata to be a very good pollen giving parent, and with its pollen used on A. vittata rubra, I succeeded in making the first break tending to the A. Mrs. Garfield mentioned in the communication just alluded to. With its pollen, too, I obtained from the now apparently lost apricot-ground Hippeastrum parlinum, which never yielded a seed when tried with its own pollen, the seeds from which A. O'Brieni was raised. This charming plant partakes of the beauty of both its parents, but I am afraid it also partakes of the weaknesses of both; in fact, it seems to be a parallel case to that of the showman's hippopotamus, which, being amphibious, he explained, "could not live on the land, and died in the water." At least, so it seems, for, although I could always manage it well, I find it has only succeeded, so far as I know, in a few other places. With the pollen of A. reticulata I also crossed that distinct plant, A. prosera (Impératrice de Brésil), known as the blue Amaryllis, but the seedlings after a time languished and died. With respect to correct lists of Crinums, Paneratiums, &c., I am afraid nothing can be done complete or accurate. Some of us know the varieties in cultivation, and others figured, but there is an amount of uncertainty about the distinctness of many of the kinds figured under different names, that until they can be grown side by side and determined, any enumeration of species must include many false ones. I have repeatedly talked over the whole question with Sir Chas. Strickland, of Hildenley, who has a good and practical knowledge of all these things, but we could never see how the mysteries were to be elucidated, or the beauty of the Amaryllids done justice to by means of coloured illustrations, at least, at present, as an illustrated work on the subject would be costly, and at first the demand for it would not give anything like a sufficient return for the time and money expended in its production.—JAMES O'BRIEN, *Narrow-on-the-Hill*.

Araucaria excelsa.—Those who are fond of trees which assume a geometrical form should grow this Araucaria, as the branches appear at stated intervals up the stem and its outline is altogether stiff and formal. Some might regard it as a nice shaped tree, and on this account it might attract attention, but I cannot say I like it. It grows quickly, and unless it can be accommodated with a lofty house, it is a difficult matter to deal with it when it attains large dimensions.—J. MUR.

SEASONABLE WORK IN PLANT HOUSES.

WINTER-FLOWERING PLANTS.—It is advisable now to look over the young stock of autumn and winter-flowering plants that have been recently propagated, with a view to making good any deficiency before the season is too far advanced to admit of the plants attaining the requisite size and solidity in the shoots before the growing season is over. It is well to bear in mind that with quick-growing subjects that are propagated annually for the purpose in question, something more than size is required to enable the plants to bloom satisfactorily. In the case of free-growing things of this character, it is possible, with the aid of a high temperature and a moist, confined atmosphere, to grow the plants up to a large size in little time, yet when the work is hurried on, the wood is so far wanting in solidity, that when the season for them to bloom arrives they show a greater disposition to keep on growing than to produce flowers.

EUPHORBIA JACQUINIEFLORA AND SCUTELLARIA MOCCINIANA.—Special attention should be given to securing a good supply of these plants. They occupy little room in comparison with the quantity of flowers they yield. With a sufficient stock of the first-named it can be had in flower from the latter end of November to April, as if the plants are as strong as they should be they will produce a second crop little inferior to the first from the young growth that is made after the first flowers borne on the extremities of the shoots are gathered. Plants of this Euphorbia that have now done flowering require to be carefully watered for the next two months. Flowering has a more exhausting effect on the Euphorbias than it has on most things, so that for a time after the plants have ceased blooming both root and top growths are sluggish, and if whilst in this condition the soil gets too much water it is more than likely the roots will perish. This applies equally to stock that is grown in pots as it does to plants that are turned out in a bed; in the case of both no more water should be given than will keep the soil from getting dust-dry until the young growth has made some progress.

TOXICOPHLEA THUNBERGI.—This fragrant free-blooming plant appears to not be yet so well known, or its good qualities so well understood as it deserves. It has the merit of occupying much less room than many things that will not yield a like amount of bloom, as when well managed it not only produces its pretty trusses of flower from the extremities of the shoots, but also in pairs at the axils of the leaves on a considerable extent of the preceding season's growth. Its somewhat spare habit of growth necessitates attention being given to pruning after the plants have flowered, otherwise they get into a straggling, unsightly condition. Plants that have done flowering should now have their strongest shoots shortened a little; after they have again broken into growth they will require a shift, but less root room will suffice than would be necessary for larger growing subjects. Cuttings of this Toxicophlea should now be put in; if they are taken off with a heel there will be more certainty of their striking. In a brisk heat, kept moderately close, moist, and shaded, they will soon root. Ordinary stove treatment is all that is required to secure free growth, stopping the leading shoot as the young plants begin to move freely.

JASMINUMS.—J. gracillimum is one of the best stove plants that have appeared in recent years. It is more dense and compact in its habit of growth than most of the other kinds, in addition to which it is a profuse bloomer, flowering from every bit of growth made, the weak shoots as well as the stronger ones. Plants that were struck from cuttings last year should now have more room; give pots proportionate to their size and the amount of roots with which they are furnished. Older specimens should at this season be turned out of their pots and have a portion of the surface of the balls removed, giving them more room if it is found that the pots are much crowded with roots. But a deal may be done in

keeping up the requisite vigour by the use of manure water during the season of active growth. J. Sambac and J. Duchesse d'Orleans are both more straggling in growth than J. gracillimum, and are better adapted for training round a pillar in the stove than for growing in the form of a bush or standard. If planted out they should not have so much root room as more vigorous growing things; their shoots should be shortened in now so far as necessary to keep the plants furnished with young flowering growth from the base upwards. A portion of the soil from the surface of the bed in which the plants are turned out should be removed, replacing it with new; if grown in pots, a larger size must be given as the roots require it. Good turfy loam with some sand and a little rotten manure suit the different kinds of Jasminum. Where young stock is required cuttings of all the kinds should be put in now; treated in the way that answers for ordinary stove plants, they will strike in a few weeks. When sufficiently rooted move them singly into small pots, and keep through the summer in a moderately warm house; they will make useful plants by autumn.

ACHIMENES.—Roots of these started some weeks back should now be in a condition for potting off or putting in hanging baskets. If allowed to remain too long in the pans in which the tubers were started, the young roots suffer in moving, so that the top growth receives a check that it is much better to avoid. In potting it is best to err on the right side by not overcrowding the plants in the pots, as when this occurs, however much they are assisted with manure water, their time of flowering is shorter than it should be, and in addition to this when they are too much crowded, the lower leaves lose the healthy green hue so necessary to give the desired appearance. More tubers should be started in heat; these will come in so as to give a succession of bloom after the earliest batch is over.

GLOXINIAS.—Another set of tubers that have been at rest through the winter should be potted. Give pots proportionate in size to that of the tubers. Large tubers make a fine display when in bloom, as they usually produce flowers proportionate in number to the size and strength they have attained, but if under-potted their flowering is of short duration, as when they have not enough sustenance, little in the way of successional flowers need be looked for. Medium sized tubers that have enough pot room given them, generally produce the largest flowers, and keep on giving successional bloom more freely than very large old bulbs, unless the latter have pot room in proportion to their size. Keep the early started plants close to the glass; a shelf over the path of a stove if such is available, where they can have their tops near the roof is the right place for them. In such a position the leaves come thick and leathery in texture, and the flowers have plenty of substance in them; so grown they stand firm and plump for several days in water when cut; whereas if, as one often sees them, they receive insufficient light, the flowers are all but worthless for cutting.

GREENHOUSE.—Old plants of Abutilons that were cut back after flowering last autumn and have been kept cool during winter will by this time have made some shoot growth and be in a condition for repotting. In the case of these and other quick-growing soft-wooded subjects that will bear a considerable portion of the old soil shaking away at the annual potting, it is not well to defer shifting them until the young shoots have attained much length, as when in this state the disturbance of the roots that takes place in getting the old exhausted soil away gives the young growth a check that prevents its again moving freely. Where the object is to grow plants to a large size they must have pot room in proportion, but for ordinary decorative use medium-sized examples are preferable, and if manure water is given regularly during the growing season the plants can be kept in an active condition without large pots. Cuttings of any varieties that it is

deemed desirable to increase should now be put in; the young, soft shoots strike readily in moderate heat. It is better to propagate a sufficient number each spring to take the place of any old plants that are discarded.

PLUMBAGO CAPENSIS.—Large examples of this fine old climber, that are planted out and were cut in after flowering, should now have as much of the old soil taken off the surface of the bed as can be got away without undue interference with the roots, replacing it with new that has been well enriched with rotten manure. If this is not attended to annually, free-growing plants like this after a time fail to make the requisite amount of growth, with a proportionate falling off in the bloom; for, though much may be done by regular applications of manure water, still, without the help of a portion of new soil, it is difficult to keep the plants in a satisfactory state. Young stock should be struck from cuttings each spring; the little plants that are raised in this way, if pushed on in a growing temperature until they have made some progress, will bloom nicely towards autumn. Small examples, thus treated and kept in 5-inch pots, will frequently produce half-a-dozen large heads of bloom. So managed, they are very useful for either greenhouse or room decoration.

SOLANUM JASMINOIDES.—This pretty climber is not nearly so much grown as it deserves to be. Where elegant white flowers, that differ from the ordinary plants one meets with everywhere, are required for bouquets and other arrangements, this is the plant to grow. The long succession of bloom that it gives when fairly treated is not the least of its good properties. It is not so rampant a grower as many greenhouse climbers, and may either be planted out in a bed of limited dimensions or kept in a large pot, the soil in which should be partially renewed at this time each season. Where planted out the bed ought to be surfaced with rich soil. The head of the plant, even after it attains full size, can be easily kept in bounds by shortening the branches in the winter. T. B.

TREES AND SHRUBS.

W. GOLDRING.

THE CONSTANTINOPLE NUT.

(*CORYLUS COLURNA*.)

THE Constantinople Nut, or Turkish Hazel, is a tree found only in very old gardens in this

Foliage of the Constantinople Hazel.

country—gardens that were planted fifty years ago, when it was the fashion to include as much variety as possible in their tree and shrub growth. Richly planted tree gardens like those

at Fulham Palace, Kew, Syon, Farnham Castle, and Westdean contain very fine, fully grown specimens of this tree, which, so far as its habit of growth and foliage go, is quite distinct from any other small tree with which I am acquainted. As an ornamental tree it possesses considerable merit, being handsome in outline and dense with its broad light green foliage. Adult trees have broad spreading heads excessively branched horizontally, generally with a tendency to lean much in the same way as an old Mulberry tree does. The most beautiful phase of the Turkish Hazel is in spring, generally in April, when it is adorned with a thousand long hanging catkins, which are much the same as those of the common Hazel, but larger. In catkin-time the tree is, of course, bare of foliage, and the catkins give the

The Constantinople Nut: fruiting twig, catkins, and ripe nut.

tree a most graceful appearance. In autumn, again, it attracts attention by its nuts, which, as may be seen by the accompanying illustrations, possess an unusual development of beard, which is so much fringed as to give the appearance of bristles. In some trees the nut-cups are less divided, but in all cases the nuts are smaller than Cob-nuts, and the kernels, if by chance one happens to find a good one, are insipid.

It is a tree that may be grown in any soil, but grows finest in heavy loams such as suit the common Hazel best. It has been planted purely as an ornamental tree by Mr. Howitz, of Copenhagen, who included it in his list of the most suitable trees for reforesting Ireland. He recommends it for underwood, but his experience of the tree in this respect must be limited. It is a native of South-eastern Europe and Asia Minor, where it grows into a lofty tree; but north of Central Europe it rarely grows beyond what we term small trees—say, from 30 feet to 40 feet high. The largest I have seen did not reach quite 40 feet. It is one of the very old introductions, having been cultivated in English gardens during the latter half of the seventeenth century. It is now rather a rare tree, and it can be only found in the largest nurseries in the country. Loudon mentions two varieties in his Arboretum,

namely, *intermedia* and *arborescens*. The first is said to be a hybrid between *C. Colurna* and *Avellana*, and the latter differs from the type in having the involucre cut into finer shreds; but this is a variable character.

Lonicera flexuosa.—Those who wish to plant a beautiful climber to clothe a wall pier, trellis, arbour, or such like, should make a note of this the most beautiful of all the climbing Honeysuckles. It may be distinguished from the rest by its slender twining stems being of a dark purple-brown, by its broad deep green leaves stained with a purplish tint, and when in bloom by its large clusters of deliciously scented flowers, coloured with various shades of yellow and reddish purple. It flowers persistently throughout the summer far into autumn—in short, it is one of the very best of all hardy climbers. It

never looks finer than when seen falling gracefully over a buttressed wall, where it forms quite a canopy of foliage and flower. It is not too late to plant it now, as hardy climbers are generally kept in pots in nurseries.

Forsythias in masses.—The slender *Forsythia suspensa* is among those shrubs that have the best effect when planted in isolated groups or massed by themselves in a shrubbery, and thus placed, nothing in the way of flowering shrubs can have a finer effect in May than this beautiful *Forsythia*. It well repays cultivating as regards mulching with manure and fresh soil, for then it makes vigorous growth, producing a thicket of its long, wand-like shoots, which yearly are wreathed with yellow. I saw the other day a bold mass of this *Forsythia* margined with a row of the small *Deutzia gracilis*, and the whole mass was edged with the variegated-leaved *Euonymus radicans*.

Forsythia suspensa.—This is one of the best of early flowering wall plants, as the long flexible branches are, before the expansion of the leaves, completely clothed with bright golden coloured blossoms, but apart from this it can also be used for other purposes. It is now flowering finely in the conservatory at the present time, and that with very little forcing. When required for flowering in this way, the plants are best confined in large pots, and if secured to a stout stake the wand-like shoots depend therefrom in a graceful manner, and when in full flower a large specimen forms a

very attractive feature. Another kind, the bushy habited *Forsythia viridissima*, can be grown under the same conditions, but its habit is altogether more stiff than that of the first named. No preparation is necessary in the case of *Forsythia viridissima*, as if the bushes are lifted from the open ground and carefully potted, they will flower well and may again be planted out. *Forsythia suspensa*, or *Fortunei*, as it is often called, will frequently emit roots where the point of a shoot comes in contact with the earth, and thus form a base from whence shoots are soon pushed up which quickly grow into established plants. —T.

RENOVATING SHRUBBERIES.

NOT for many years have the winter's snowstorms left such serious marks behind them as that through which we are now passing. The damage done to choice trees and shrubs is in many cases very great, and how best to repair it is a question that must be considered. I have never known very

to do this, as will also young plants of *Arbutus*, *Box*, *Laurustinus*, *Phillyreas*, and *Gum Cistus*. It is unnecessary to cut all the remaining branches back to a stump; they only require to be shortened to bring the head into better form. Such subjects as *Ilex*, *Thorns*, and *Hollies* may, if badly damaged, be pollarded; but, generally speaking, it is best to cut all the branches back to within 4 feet or 5 feet of the stem. Once *Conifers* have lost some of their main branches they are not easily replaced. Nor is it desirable, with a few exceptions, to expend much labour on an attempt to restore aged trees that are much injured. If they cannot be spared, plant young ones in the same line, either before or behind them, to ultimately take their place. In all cases, more satisfactory results will be obtained if the roots are attended to at the same time as the branches. Where there are valuable specimens which it may be desired to retain and the soil is known not to be of the best description, it will help them considerably if some of the old staple is removed and

is excellent for this purpose, but when these are not available use the next best that comes to hand. Before this sort of work is begun it is necessary that every part should be gone over, to see what plants are likely to respond to such treatment. If too much weakened by age or other causes they had better be removed and young ones put in their place, and any that are overcrowded should either be pruned hard back, or some of them should be altogether removed in order that those left may stand quite clear of each other. This is the proper time to prune all evergreen shrubs and such of the deciduous kinds as flower on the current year's wood. Those which are encroaching on walks should always be pruned with a knife; shears should not be used, as they leave the surface too smooth to look well, and instead of cutting back all the small twigs some of the larger branches should be cut out nearer to the stem than they would be by shears. Now is also the best time to go over *Laurel* plantations and banks; the knife alone should be used for the latter, but in the case of large plantations strong nippers are best. *Laurels* are very accommodating as regards pruning; those with large boles will break into strong growth at any point to which they may be cut back, but in the case of very old plants the nearer they are cut down to the ground the better. *Laurustinuses* are for the most part now in full flower, and it would be a mistake to spoil their beauty when pruning may be advantageously deferred for a few weeks longer. It is too much the practice to prune all kinds of shrubs at one and the same time. Shrubs should all be pruned as soon as they go out of flower, a statement which applies particularly to *Rhododendrons*, but in dealing with plants of large size it is better to cut them down to one uniform height or nearly so. If some are cut hard back and others left unpruned, the unpruned branches invariably monopolise the whole strength of the roots and the cut-back branches decay. It should, however, be remembered that the less *Rhododendrons* are pruned the better they flower. Cultivators of hybrid *Rhododendrons* should go over them once a year, and remove any suckers that may have arisen from the crown of grafted plants. The experienced grower will have no difficulty in ascertaining which shoots belong to the stock and which to the scion from the colour of the foliage; that of the stock is usually a darker green than that of the scion. Where any doubt exists this part of the management should be delayed until the plants are in flower.

With regard to filling up vacant places, the sooner all deciduous subjects are planted now, the better chance they will have of forming new roots before the summer sets in. In the case of *Evergreens*, I would rather plant in April than in March. I find when planting *Evergreens* in spring that they invariably move best just as growth commences, or rather when it is on the point of starting; but long experience has convinced me that whether planting is done in winter or spring, a good deal depends on the character of the weather which follows. If severe frost follows immediately after winter planting the injury done is often great; indeed, not unfrequently the plants are killed; when planting is done in April, and drying cold winds and an absence of rain follow, the result is often disastrous. But at any time I would much rather have to contend against unfavourable climatic conditions late in spring than in winter. Trees or shrubs which require stakes should now be supplied with them, and those which have been staked for some time should be examined to see that they are sound, and also the ties. Any choice trees or shrubs which have been recently planted in places much exposed to sun and wind should have a mulch of half-rotten manure laid over the roots for the purpose of confining moisture in the soil. J. C. C.

SHORT NOTE.—TREES AND SHRUBS.

Prunus Pissardi.—I see by THE GARDEN (p. 238) that this shrub has been exhibited at South Kensington in pots from under glass. Here with me it has been in full bloom out of doors for the last ten days. The contrast between the

Corylus Columna (Constantinople Hazel). Full-grown tree at Syon, 61 feet high.

satisfactory results to attend any attempt to restore trees and shrubs of large size that have been much injured in this way; therefore in the majority of cases it will be best to grub them up. Any tree or shrub, however, that was in vigorous health before being damaged will be likely to respond to renovating measures. Trees which under ordinary circumstances have only a limited number of large branches will be the least likely to recover and make handsome specimens. Such subjects as the *Horse Chestnut* and the *Beech*, which are usually well furnished with limbs and not too old, will prove eligible trees to operate upon if not irreparably injured. The *Cedar* and *Yew* are both remarkable for their recuperative powers, and I should hesitate before I removed them to make room for young trees. The same remarks apply to shrubs and trees of more diminutive growth. Some, if judiciously pruned now, so as to balance such growth as is left, will in time assume their original contour. *Common* and *Portugal Laurels* will be pretty sure

some good rich earth substituted. In doing so there need not be much root-disturbance, as the principal roots can be traced as far as it is desirable, which, in the case of large trees, should commence at 6 ft. from the bole, and be continued for a space of from 8 feet to 10 feet. Where so much labour cannot be expended, the benefit arising from a surface-dressing of good soil laid on the roots is surprising; but what would have an earlier effect on trees that have lost limbs would be first a layer 6 inches thick of good manure and then a covering of soil.

The most speedy and satisfactory way of renovating shrubs which have lost vigour is first to prune them moderately so as to reduce the strain upon the roots, and then to dress the surface with a layer of good soil at least 6 inches thick; there is, too, no better time for doing such work than the present; almost anything in the way of fresh earth will do good, but the better it is the more benefit the plants will derive from it. Good loam mixed with an equal quantity of farmyard manure

dark coppery foliage, dotted over with myriads of pinkish white flowers, is admirable. So much for our mild southern climate.—W. B. H., *York*.

KITCHEN GARDEN.

W. WILDSMITH.

SHELTER FOR KITCHEN GARDENS.

ON the principle that each thinks his own misfortunes the worst, I have, I suppose, imbibed the idea that in no part of Britain are bitter north-easterly winds so severely felt as here. Be that as it may, however, we certainly get them to some time all through the early spring-time, and having this season begun their annual raid we are busy taking steps to counteract their disastrous effects on all early vegetable crops. We have good walls, and they do much to break the force of the wind, though over some two-thirds of the garden the current sweeps down in full blast, infinitely more damaging than frost, and some kind of shelter is imperative in order to keep early Peas, Lettuces, Broad Beans, Cauliflowers, Spinach, early Potatoes, and transplanted Onions in vigorous growth. We usually stick Peas on the windward side as soon as sown, and when well out of the ground they receive additional protection by means of thicker spray. Lines of pyramidal Peas also greatly break the wind, as do also Raspberries trained to strained wire fencing that runs the entire length of the garden. We have lately planted small bush trained Apples on the dwarfing stock with the same intent; Black and Red Currants in lines a good distance apart, so as not to shade the vegetable crops too much, would serve the same purpose. Much as one dislikes this mixed way of growing fruit and vegetables together, there is much to be said in favour of the plan, especially as regards early vegetables. The warm border, invariably recommended to be made use of for every description of early vegetables and salads, is no doubt the proper place for all such crops, but unfortunately there is a limit to its extent, and owing to this some few years ago we determined on doubling the extent of such borders. This we did by taking a slice of 12 feet from the entire length of the kitchen garden, and being taken from the upper portion of the main plot it has a full southern exposure, has a thick screen of Pear trees on the northern side, and in order to make the position still warmer the ground was thrown up into the form of a bank, slanting to the south. The plan has succeeded beyond our expectations; indeed, the crops from this border are quite as early as those from borders in front of south walls. This question of shelter for the vegetable garden, though of the greatest importance as respects forwarding early crops, is by no means limited in its beneficial effects to these, as everyone would be ready to admit if, after a severe gale in early autumn, they would take the trouble to examine the effects that the wind had on such crops as Brussels Sprouts, Broccoli, and French Beans; a deep cavity at base of the stem will all too plainly show the injury that accrues from lack of shelter, and which, perhaps, may serve as an incentive to the devising of ways and means to prevent a recurrence of the damage. Possibly, in many instances, this may be a difficult matter, and those who experience that difficulty will probably be all the more careful, if ever called upon to select a site for a kitchen garden, to secure shelter, which is hardly less important than good soil.

Brussels Sprouts sown in March under glass are now, I find, 3 feet high, and studded with sprouts, which are simply Cabbages in miniature. The frost has affected them severely, browning them as if fire

had passed over them; while in the self-same plot we have also Brussels Sprouts sown outside in the first week in May, green, fresh, and beautiful to the eye. Large knobs of Brussels Sprouts are by no means wanted; they should be about the size of an ordinary Walnut. The large size of the March-sown stock renders it simply uneatable, whilst the produce of those sown in May is at the present time passable. In order to have a few early Brussels Sprouts, they should certainly be sown in March, but for the main crop May, with me, is the proper month in which to sow.—R. GILBERT, *Burghley, Stamford*.

BOX EDGINGS IN KITCHEN GARDENS.

THERE is always a danger of anyone who suggests new or economical practices where extravagance has been the rule being taken to task for his interference, and those who have suggested that trim Box edgings, kept up at great expense round Potato and Cabbage quarters, &c., were an incongruity and a waste of money, seem to be regarded by some in this light. We are assured that Box edgings in kitchen gardens are the best, and that the labour of keeping them is not great. Now, here is an example that could be multiplied by the score. In the establishment in which I first learned, the kitchen garden was a mile from the house, and as the proprietor and his family only resided there for six weeks or two months in autumn, and did not see the kitchen garden above two or three times at the most during their stay, it could not be said that the Box edgings contributed greatly to his enjoyment, but there was no doubt of their cost to him.

In that kitchen garden there were 4 acres inside the walls and as many outside, and the extent of the Box edgings was about 8000 feet—getting on for 3000 yards! Imagine the cost of laying, keeping, and trimming such an extent of edgings of that kind, and all for what? for an idea; for practically nobody saw them but the workmen, who were being continually cautioned to be sure and clean out the Box edgings first when they were digging the plots inside or cleaning the walks outside, and never to go over them with a barrow except on the "bridges," of which a supply was kept for the purpose. In the next garden I went to it was the same. Owing to depressed times both gardens are now practically shut up or turned into market gardens, and I fancy the Box edgings will not be so trim as of yore. Is there, I ask, a good kitchen gardener anywhere who desires some reasonable balance to be preserved between his debtor and creditor account for vegetable crops, who would in these days recommend such a garden as I have described to be furnished with Box edgings or any other as expensive? Kitchen gardens, pure and simple, seem to be under discussion, and it is of these I speak. In the days when proprietors had to depend on their kitchen gardens for produce of all descriptions it was different, but now, when almost everything can be furnished cheaper than it can be grown at home, considering the uncertain and fluctuating nature of the demand in private places, our kitchen gardens must be managed on a different footing; and as reduction of expenses is the order of the day, and likely to be for a long time to come, it behoves those who offer counsel on such subjects to consider well the position of affairs, and offer such advice as can be generally accepted.—S. W.

I am sorry to see Mr. Wildsmith (p. 239, March 12) oblivious of the fact that the best and prettiest of all edgings for either kitchen or flower garden are pieces of thin stone, in their natural cleavage, so to say. They get nice in colour and often mossy; are easily set, never offensive, and never any trouble to keep or form.—A HATER OF CAST EDGINGS.

Coloured *versus* white-skinned Potatoes.—I was recently invited to send a collection of half a dozen kinds of Potatoes to Ireland that their usefulness for desiccating purposes might be tested, two of which were coloured. Although the white sorts were such as would have been regarded as of first-class quality here—flesh white and mealy or floury—yet they seemed to have been found lacking body when subjected to pressure. Thus, it is evident that many

of our whitest, most floury, and most fancied Potatoes lack solidity as compared with some others. The coloured sorts, however, gave satisfaction, and are to be grown for further trial in the north of Ireland during the coming year. Both have semi-yellow flesh, and it is worthy of remark that not only are such Potatoes invariably the best flavoured, but give the most satisfying food. The Victoria has that quality somewhat; hence its undoubted superiority to all other field Potatoes some years since. The two kinds which passed the desiccating ordeal are The Dean and Bedford Rose, and it is worthy of remark that both are products of Mr. Fenn's Woodstock Kidney, that kind being the pollen parent. In spite of adverse accounts I have always regarded Woodstock Kidney as being one of the very best flavoured and cooking Potatoes in cultivation. It has two demerits—it is handsome, and thus got abused, and it is liable, because of the thinness of the skin, to disease; still it is a first-class parent. The chief object of the desiccating or preserving process is to furnish a concentrated form of Potato food for export, and is largely used in the army and navy when on foreign service.—A. D.

Duke of Albany Potato.—This kind is really a white-skinned Beauty of Hebron, and is one of the very earliest ripeners we have. It is of the usual American quality, which improves somewhat under English cultivation. Like the Beauty of Hebron, Early Rose, and similar early sorts, it is a difficult Potato to keep through the winter as seed tubers in bulk, as growth is inevitable soon after Christmas, and by the planting time have required much dis-budding. All such kinds should be stored only in baskets, boxes, or on broad shelves where the tubers can obtain ample air. A market grower just planting a quantity of the Beauty mentioned [that his stock had grown a good deal, and therefore of necessity was much deteriorated as seed.—A. D.]

Broccoli, Penzance Early White.—Many who read about, or have an opportunity of seeing, some of the large consignments of Cornish Broccoli, notably those sent from the Penzance districts, and which reach various parts of the country, are naturally easily led to believe that this superior earliness and quality must partly result from sowing seed of an extra good variety. The consequence is, a trial is given to the Penzance Early White. They then discover that Cornwall is a highly favoured county and that what may be hardy and good there is delicate and useless in colder districts. I have received both seeds and plants in quantity direct from market gardeners in the neighbourhood of Penzance, and have also tried seed obtained from reliable London seedsmen, and in each instance a fair trial was given. It proved to be of very vigorous growth, forming long, easily crippled stems, a very moderate frost completely spoiling the breadth. It is not so hardy as Veitch's Autumn even, and if this proves to be the case in our comparatively warm county those farther north ought certainly not to waste either time or space in cultivating it. Not many Broccoli of any sort have survived the late winter, and only those planted on firm and rather high ground are alive in this district, but no method of culture could have saved the Penzance.—L. *Somerset*.

The Puritan Potato.—From Mr. Peter Henderson, of New York, has come per mail a single tuber of this new American Potato. As is so commonly the characteristic of the breed, it is long, narrow, and much beset with eyes, though shallow ones. Upon this tuber of about 3 ozs. weight I count some sixteen to eighteen eyes, all more or less showing growth. Of course this feature enables tubers to furnish numerous sets, but, on the other hand, it promotes early exhaustion, as, instead of but one or two shoots breaking only, as is the case with so many of our English kinds, when all the eyes break the absorption of the nutriment of the Potato is rapid. I think that characteristic has helped to render American Potatoes less popular with us than our own kinds are. The Puritan is a white-skinned kind, and shall have a fair trial.—A. D.

Triumph Pea.—This is, no doubt, one of the coming Peas. It is a wrinkled Marrow of moderate height, and pods wonderfully. The pods are long, large, and handsome, and full of Peas. I saw a quan-

tity of the best new Peas growing in the large, open kitchen garden at Glenhurst, Esher, last year, where all were staked, and did as well as Peas possibly could. I regarded Triumph, however, as one of the very best; it cropped grandly. It has also high Marrow flavour. In time I should expect to see this Pea popular amongst market gardeners, but it must be conceded that no such fair test of the merits of any Pea can be furnished in a field as when staked and grown in good garden soil. The advertised pictorial representations of Pea-pods are often amusing, especially when some are shown open with Peas so large in them, that they could not possibly have existed in the pod when closed. Illustrations of this kind rather tend to detract than otherwise from the merits of what may be really excellent things.—A. D.

KITCHEN GARDEN NOTES.

BEEF.—It is much too early to sow other than the smallest patch possible, by way of continuing the supply in cases where the store is getting low. As a matter of course, the risk of seeding instead of bulbing from such early sowing is great, and is much influenced by the weather, which if cool and moist throughout April and the first part of May, there will be very little disposition to premature seeding, but opposite weather conditions will have the contrary effect. We have a good store, and shall therefore not require to sow till the middle of next month, but the importance of the crop necessitates that foresight and the reservation of a suitable plot of ground should be exercised. Ours is destined to occupy part of the ground, that was—part still is—cropped with Celery, and which will be trenched deeply, but no admixture whatever added. We shall then get depth of soil and well enriched by the thorough incorporation of the manure that was used last year for Celery. Smooth, fangless roots of medium size are those that are most valued, hence rank or fresh manure is very unsuitable, but, on the other hand, if the soil be very poor—as we have practically tested—the produce is so hard that no manner of cooking can make it soft and palatable. From the foregoing it will be observed that a good deep, but not recently manured soil is that to be preferred, whether light or heavy—so long as the latter is well drained—it matters little, except that at sowing time a little lighter soil should be scattered in the drills of the heavy soil, and the seed be covered with the same. Sowing should be done in drills a foot apart, and the seedlings be thinned at to 9 inches as soon as it is safe to do it. The only variety that we grow is Dell's Crimson, a sure indication of its superiority being the numerous synonyms under which it is grown.

PEAS AND POTATOES.—Those raised in heat we have now planted out on a south border, and have effectually screened them with boughs from the cold north-easterly winds that never fail to annoy us by their prevalence at this season of the year. Birds are about as annoying and more destructive than the winds, and in self-defence we give them unappreciated condiments—to season the tender young Pea shoots that they are so partial to—in the form of tobacco powder, soot, and lime. We have to adopt the same measures with Peas now coming through the ground, as also with Radishes that are sown between the rows of Peas. The weather has tempted us to plant more Potatoes, but having visions of early May frosts, that in previous years have cut down the haulm to the ground line, we intend to resist all further temptation in that direction till April; but meantime, by way of advancing and keeping the work well in hand, the drills will be drawn, and on ground that needs additional stimulants we shall sow in the drills whatever artificial manure we can command. We have a large piece of gravelly land that force of circumstances compels us to crop with Potatoes year after year; and a few years back being driven as it were to desperation for want of manure, after the Potatoes were planted we gave the whole piece a dressing of salt, quite as much as is usually applied to Asparagus; results—as fine a crop of Potatoes as anyone could desire.

My theory in respect of the salt proving so beneficial is that the soil, though deep, is full of stones—in fact, nearly pure gravel—and burns up quickly in a hot season, but the moisture given off by the salt having a cooling effect on the stones, and through them on the whole ground, consequently in the hottest weather the soil remained cool and moist.

AUTUMN BROCCOLI AND SAVOY.—There is nothing like paying dearly for one's mistakes to make us the more careful in future; over-anxiety to have everything in its proper season sometimes ends in having nothing. Such has been our fate in respect to Broccoli by sowing too early, that the plants got stunted before we could find ground to plant them out, which, as a rule, cannot be had till early Peas, Potatoes, Spinach, and early salads are off the ground, and if one may use the expression, it is by taking the measure as to when that is likely to happen that shall determine the time of making the general sowing. At present only a very small sowing of Broccoli should be made for early autumn supplies, and the varieties we have found most constant at that season are Snow's, Veitch's Protecting, and Autumn Giant Cauliflower, the latter being in my opinion far superior to either of the Broccoli, but, unfortunately, it is not so hardy; if it were, there would be little need of growing any other variety, as by sowing at various times a continuous supply could be had all the year round. Sow in light soil and in drills on a sunny bank, and protection from birds with netting should be put over as soon as sown. To have Savoys in time for the grouse in August, which in some parts is considered the proper thing, a sowing of Early Dwarf Elm should be made now. There is a small early variety named Tom Thumb that hearts very early, and where ground is limited, that is a good variety to grow on any bit of spare border or under the shade of fruit trees. It need not be planted further apart than 9 inches each way. The general sowing of Savoys need not be made for another month or more.

BRUSSELS SPROUTS.—If these have not been raised in heat, no time should be lost in making the principal sowing on the best ground and most open spot that can be spared. To have stems of a less length than 30 inches is very poor cultivation indeed, for without length of stem neither quantity nor hard sprouts can be had. We always reckon on getting stems a yard long at least, but to do this the plants are raised in heat, and are now pricked out in cold frames and will be ready for planting out early next month. The ground is ready, except drawing the drills, which will be some 9 inches deep, which plan in part prevents the necessity of ridging up the stems higher than is usual for ordinary Cabbage. Reading Exhibition is our favourite variety, and is the most productive I have ever grown. The sprouts are always firm, of medium size, and the quality of the first order.

TRANSPLANTING AND SOWING ONIONS.—Those transplanted a few weeks since have felt the effects of the severe frost; we have had them re-firmed in the ground, and they may now be expected to make a renewed attempt at growth. Those now to be transplanted are stronger, and in the mellow, rich soil they are to be planted in we expect to have fine bulbs at a very early period. We allow a space of 14 inches between the rows, and of 9 inches from plant to plant. The ground has been consolidated by rolling, and the dibber will do for the final firm pressing of the roots into the soil. Though already rich, we have been extravagant enough to give the ground a dressing of bone dust, and soot will be dusted all over after the Onions are planted. Our main crop is sown, and if the present dry weather continues we shall run the roller over the ground before the seedlings emerge from the soil. This pressure we do to ensure immediate contact of every seed with the soil rather than from any benefit that Onions are supposed to derive by the ground being hard.

VEGETABLE FORCING.—These cold winds necessitate constant watchfulness in respect of renewal

of linings to frames and nightly covering up. Potatoes should have additional soil as roots are seen near the surface. Thin out Radish and transplant Lettuce and Cauliflowers that were sown with the Potatoes to other frames or warm borders; none of these temporary crops should ever be allowed to injure the principal ones. Other batches of Seakale and Asparagus should be put in according to the demand. The crowns of the former ought now to have heaps of ashes or Cocoa fibre placed over them; the Kale thus produced is, I think, sweeter than that which is forced. There will be no need to lift any more Rhubarb, as it will come right well if pots or boxes are placed over the roots without any other covering.

GENERAL WORK.—Lifting, replanting, and repairing Box edgings, turning gravel walks, adding a surfacing of new gravel, and rolling them till hard to the tread. There is just the same measure of satisfaction to be extracted from perfect kitchen garden walks as from those of the more ornamental parts of a garden, and all heavy wheeling being over for the season, now is the time for all that have not experienced that feeling to make a bid for it by setting about the work in earnest. Removing mulching from Globe Artichokes, and forking between the rows. The winter has caused some blanks, and there are no suckers, so we shall have to hasten on the seedlings that were sown in heat. W. W.

FERNS.

W. H. GOWER.

THE TODEAS.

This genus of Ferns comprises a few plants nearly allied to the Royal Fern (*Osmunda regalis*). They are found in South Africa, Australia, New Zealand, and in the Fiji Islands. They form two distinct groups, one having large and bold coriaceous fronds, the other having fronds thin and pellucid in texture; the latter are indeed placed by some authorities in a separate genus, that of *Leptopteris*, but there is nothing but the difference in texture to distinguish the two genera. *T. africana* is the plant upon which the genus was established. It was introduced into this country from the Cape of Good Hope about the year 1805. This plant had been previously named by Linnaeus *Acrostichum barbarum*, but as it does not exist in Barbary the specific name seems inapplicable; different authors have named it *Osmunda barbara*, *O. barbata*, and *Todea barbara*. The well-known Australian explorer, Allan Cunningham, sent home from that country a similar plant under the name of *T. australasica*, also known as *T. rivularis*, but the Australian and African plants are now considered to be identical. Notwithstanding this decision, however, under cultivation the African plant does not attain to anything near the proportions that the Australian plant assumes, nor is it such a vigorous grower; its fronds are more triangular in outline, and the plant altogether is more spreading in habit. The Australian plant produces fronds from 3 feet to 6 feet in length, or more, lanceolate in outline, twice-divided (bi-pinnate), the pinnae being thick and leathery in texture and some 9 inches long; the basal half of the segments (pinnules) bear a dense mass of chestnut-red sori, which form a broad central stripe of colour on the frond. In damp ravines in Victoria this plant attains gigantic proportions, masses of it having been sent to Europe by Baron Müller measuring some 6 feet in height, more than that in diameter, and over a ton in weight; some fine examples of it exist at Kew. This Fern is not, however, confined to Victoria, as some years ago we received specimens of it from Queensland, where it was collected by Mr. Walter Hill in, we believe, the vicinity of Rockingham Bay. The dimensions here given of this *Todea* need not deter amateurs from adding it to their collections, for such gigantic masses as those just alluded to must be of great age. Young plants, although they soon become handsome specimens, are many years before they outgrow the accommodation of an ordinary sized Fern house. *T. (Leptopteris) hymenophylloides*, also known by the name of *pellucidata*, produces fronds triangular in outline from

12 inches to 18 inches long, and from 6 inches to 9 inches wide in the broadest part; they are, however, more frequently of smaller dimensions; the fronds, which are twice divided, have elegantly cut segments, whilst the texture of the pinnae is thin and membranous, and the colour deep green. It comes from mountain ranges in New Zealand. *T. superba* is also a New Zealand plant, popularly known as the Ostrich-feather Fern from the resemblance of its fronds to the curled plumes of that bird. In outline it is vase-form; the fronds are some 18 inches or 24 inches in length, tapering at each end; the points of the segments curl upwards, giving the fronds a peculiarly beautiful crispate appearance; they are bright green when young, but become dark green when old. *T. intermedia*, originally introduced by Messrs. Rollisson, is a magnificent Fern, partaking as it does of the characters of both the two previously named kinds, but it does not possess the vase-like form of *superba*, although its fronds are somewhat recurved; they taper at both ends, like those of the last-named plant, and, like it, are slightly crispate, but in other respects its vivid green fronds possess the characters belonging to *hymenophylloides*. Some fine examples of the

moist spots in a tropical fernery, and are equally at home in a cool house; we have seen them growing vigorously in an unheated pit, with the protection of a mat in sharp, frosty weather; whilst as ornaments in a Wardian case in dwelling-rooms, the filmy-fronded kinds are unequalled. Wherever grown, however, the sun's rays should never reach them, but do not shade them with green glass, or the beauty of their elegant fronds will be destroyed. These plants enjoy moist air; their fronds like to be frequently bedewed with the syringe, whilst the roots must be kept wet, but water must never stagnate about them. The soil should be good, spongy peat, a little loam, and some sharp river sand.

Hemionitis Mulleri.—This rare plant, which belongs to the *Sericonitis* division of this genus, will prove extremely ornamental in small hanging baskets. It has pinnate fronds about a foot in length, the pinnae being oblong, and densely clothed beneath with silky, squamose scales, but less so on the upper side, which is deep green. The fronds bear some resemblance to those of *Notholena trichomanoides*, but the venation is reticulated. It is a native of the

Todea Wilkesiana.

three plants last named may be seen in the cool Fern house at Kew, where, however, their beautiful tints are completely ruined by being encased with green glass. *T. Fraseri* resembles the last in general outline; its pinnae are alternate, the segments more distant, and the lip finely divided. It comes from New South Wales. *T. Wilkesiana* is a very beautiful plant, as a glance at the annexed illustration will show. It appears to be common in wooded districts of the mountains of Somosomo, in the Fijis. It was discovered some years ago by a United States exploring expedition, and named in honour of its commander, Commodore Wilkes; whilst for its introduction to this country we are indebted to the Messrs. Veitch. It usually grows from 3 feet to 5 feet in height; the stem is very slender, not larger than an ordinary walking-cane, but they are occasionally stouter. The fronds, which are twice divided, are some 2 feet in length; the pinnae are alternate, and about 9 inches long, the segments being winged to the stem, membranous in texture, notched on the edges, and deep green.

Todeas are not difficult to cultivate; they thrive in

northern parts of Queensland, and is named in honour of Baron Müller, director of the Botanic Gardens, Melbourne. We recently noted this novelty under the name of *Gymnogramma Müllerii* in the Kew collection.

Ficus repens.—I quite agree with "W. I.'s" remarks as to the hardiness of *Ficus repens*. During the summer of 1881 I planted out two from 3-inch pots, one on each side of the front door of a mansion in Cornwall. Though the following winter was a severe one, and many plants were injured by frost and cutting winds, the *Ficus* passed through it and the three following safely, and I have no doubt but that they are still doing well. Cornish winters are mild as a rule, but these plants had no exceptional advantages, for they faced due east and had a bleak position. They were not protected in any way, being only planted for summer effect, and were not expected to live through the winter. A young *Ampelopsis sempervirens* growing on the same wall seemed to suffer more than the *Ficus*, though neither was injured to

any great extent, the tips of the shoots only being slightly browned. I think it must be hardy enough to pass through an ordinary winter in any part of England.—C. T.

ORCHIDS.

W. H. GOWER.

ORCHIDS IN BLOOM AT KEW.

THE houses devoted to Orchids at Kew are just now very gay, and the plants are in a fairly thriving condition. Amongst the best kinds now in bloom are some good examples of the fine old *Dendrobium fimbriatum oculatum*, with numerous pendent racemes of rich orange-yellow flowers, the lip being beautifully fringed and heavily blotched within with velvety-like black; some excellent forms of *D. nobile* (Pierardi), the ivory white *Jamesianum*, and the violet-scented *heterocarpum*. Amongst other species were some excellent varieties of *Wardianum*, which the authorities still consider a variety of *Falconeri*; the delicate and beautiful *crepidatum*, and a white-flowered form of the Australian *Kingianum* may likewise be seen here. The lovely, but very fugitive flowers of *Sebralia sessilis* were numerous, as were also many forms of *Lady's Slipper* (*Cypripedium*), the principal kinds being *C. villosum* and its near ally, *Boxalli*. Associated with these were also *C. porphyreum*, *Roezli*, and *Harrisianum*, and good varieties of *C. Leeanum*, *concolor*, and *venustum*. Moth Orchids (*Phalaenopsis*) were not numerous, but one plant, *P. Stuartiana*, was bearing a branched spike bearing between forty and fifty flowers, large in size and beautifully spotted. *Aerides vanderum*, with its pure white flowers, *Saccolabium giganteum* and *bellinum*, with large flowers heavily blotched, *Vanda tricolor*, and *Angraecum citratum* were the most noticeable of the erect distichous-leaved kinds. Numerous plants and varieties of *Lycaste Skinneri* were very attractive, as were likewise some well-grown specimens of *Celoglyne cristata*. *C. elata* is a species that has been in the collection many years, but, singular to say, has not become popular. It is now in flower, and should commend itself to every one. The flowers are not waved on the edge, as are those of *C. cristata*; they are white as driven snow, with a somewhat crescent-shaped, transverse band of yellow on the middle of the lip and two narrow fringed lines of crimson running through it. *Masdevallias* now in flower are *igneae*, *Lindeni*, *Chelsoni*, *triangularis*, and *cucullata*, the latter with large blackish purple blossoms; and the beautifully-spotted and dotted *melanopus*.

Amongst *Cattleyas* and *Laelias* were examples of *C. bogotensis* and *L. harpophylla*, which appears to be a wonderfully free bloomer, although we cannot believe it to be a variety of *L. cinnabarina*, whilst another similarly coloured flower is *Ada aurantiaca*, now in great beauty. *Odontoglossums* were represented by good varieties of *triumphans*, *Halli*, *Cervantesi*, *Erstedii majus*, *crispum*, *blandum*, and *luteo-purpureum*, whilst several other kinds of a somewhat inferior character need no comment. Miscellaneous and less well-known Orchids were represented by *Sarcophilus Hartmani*, a species from Australia with distichous, deeply channelled leaves some 6 inches long, and bearing a scape about a foot in length, with a raceme consisting of about two dozen flowers. The sepals and petals are waxy-white, the sepals being slightly the broadest, and transversely barred at the base with dotted lines of crimson. The lip is very small. *Oncidium aureum* is a distinct species with dull crimson sepals and petals, and a broad, deep orange-yellow

lip. *Ponthieva maculata* is a most elegant and distinct plant of terrestrial habit about a foot in height; the leaves are somewhat oblong-acuminate, pale green, and covered all over with long white hairs. The scape is terminal and erect. The flowers are not large, but numerous. When reversed the lateral sepals stand uppermost and form the chief attraction; these are joined at the edges for about half their length (connate), white, conspicuously marked with round, dark green dots, and fringed round the edges with white glandular hairs. *Eria obesa* is a small-growing plant suitable for a block. It is one of Parish's discoveries in Burmah some years ago; its pseudo-bulbs, which are short and much swollen, produce numerous trusses of white flowers. This and the curious *Mormodes Colossus* close the list. If this is the true *Colossus*, it certainly is not well named, as we have several others much larger, both in pseudo-bulb and flower.

Dendrobium nobile.—Just as a reminder of the usefulness of the old *Dendrobium nobile*, I send you a photograph of a small plant of it in flower here at present.—A. McDONALD, *Tayside Gardens, Perth.*

* * A photograph of a profuse-blooming specimen. We hope the art of photography will be more and more used in gardens to preserve souvenirs, so to say, of this and many other pretty plants in interesting states. Other things that men collect are always, or nearly always, the same, but we may never again see plants in the same condition of beauty owing to a variety of circumstances, and therefore the art of photography as a means of preserving some of our garden results is of the greatest value.—Ed.

Cypripediums at Studley House.—During the last twelve months a choice collection of Orchids has been brought together here by Mr. F. G. Tautz. The special favourites are the Ladies' Slippers, of which there are 160 species and varieties, forming in its way quite a unique group. This genus does not contain richly coloured or showy species like *Cattleyas* or *Dendrobiums*, but it nevertheless contains some interesting plants, many of which are beautiful, and the new hybrids recently raised and introduced by Messrs. Veitch and others have quite revolutionised the genus. One of the showiest species, and a recent introduction, is now in flower, viz., *C. callosum* from Siam. It is handsomer than *C. Lawrenceanum*, to which it bears considerable resemblance. The flowers, which are very large, are 5 inches across the lateral sepals; the latter are greenish with rosy tips and dark spots on the upper margin; the dorsal sepal is 3 inches wide, the upper portion being whitish and red veined. *C. Argus* is a well-known and striking species for flowering in winter, and varies considerably, some having the lateral sepals more densely blotched and spotted with reddish chocolate than others. *C. Peteri*, a Bornean species, was opening its flowers; it is allied to *Dayanum*. *C. concolor* was also in flower. *C. insigne biflorum* is a distinct and pretty form of this good old species; the greenish dorsal sepal has a white margin, and is very thickly blotched. *C. Dautleri* is merely a form of *C. Harrisianum*. *C. calurum*, one of the Chelsea hybrids, has been in flower all the winter, and a most useful species it is. *C. Sallieri*, which is pretty, is a recent hybrid between *C. insigne* and *C. villosum*; it seems to have caught the characteristics of both parents. *C. calophyllum* also bears evident traces of its parentage, viz., *C. barbatum* and *C. venustum*; the dorsal sepal is white with a rosy tinge, and is marked with greenish lines. *C. Williamsi*, recently alluded to in THE GARDEN, is also in flower. Many of the choicest species and varieties are not in flower, but the plants are in good health, and in a year or two will be very attractive.—J. D.

Dendrochilum glumaceum.—This is a member of a small genus of Orchids found growing upon the branches of forest trees in the Malay Islands. The generic title has recently been altered by Bentham to *Platyclinis*, which certainly has no more agree-

able sound than *Dendrochilum*, and we doubt if it will be readily accepted by Orchid growers. The *Dendrochilums* are all plants of dwarf habit; they have small pseudo-bulbs which support a solitary leaf, and the flowers individually are small and borne on long, slender, pendent racemes, arranged in a two-ranked fashion. *D. filiforme*, which blooms in summer, has long, slender racemes of golden yellow flowers, and is popularly known as the Golden Chain Orchid; those of *D. glumaceum* are greyish white, and yield a grateful perfume, somewhat resembling that of Hawthorn and Heliotrope mixed. This species is grown largely by Sir Trevor Lawrence, in whose collection we recently observed it in great perfection.

Orchids at Wimbledon House.—Flowers are largely grown in these gardens for the special purpose of cutting, as Sir Henry Peck delights to distribute them amongst the poor in the sick wards of the London hospitals, and a goodly stock of Orchid blooms now largely contributes to the supply. We observed at the time of our visit a houseful of *Cologne cristata*, the plants being literally covered with hundreds of their lovely pure white flowers. Numerous plants of *Lycaste Skinneri* are also now blooming profusely; and so are *Phaius grandifolius* and *Dendrobium nobile*. The last named, although an old variety, is eclipsed in point of beauty by but few, even in these days of great introductions. *Odonoglossum* are also largely grown, such kinds as *Alexandrae* (crispum), *Pescatorei*, *gloriosum*, and *Rossi majus* being now in flower, together with several of the bright-coloured *Masdevallias*, such as *ignea* and *Harryana*. *Cypripediums* are grown in quantity; several kinds have been cut, but there are still some fine forms of *villosum*, *venustum*, *Stonei*, and numbers of the beautiful white *niveum*. *Dendrochilum glumaceum*, although not a showy plant, yields a delicious perfume. The plants are grown in hanging baskets, and appear to be thoroughly at home in that position. We also noted a very fine form of the Duke of Devonshire's *Dendrobium* (*D. Devonianum*), which is perhaps the most exquisite member of the genus in cultivation. It has, however, to some extent lost popularity on account of its blooms being somewhat fugitive.

SHORT NOTES.—ORCHIDS.

Cattleya Trianae Vanneriana.—This variety, exhibited on the 5th inst. at South Kensington, deserves more than a passing notice. It flowered for the first time in Mr. Sanders' collection at St. Albans, and also in that of Mr. Vanner, in compliment to whom it is named. The sepals have each a distinct orange stain in the centre, and there are on all, or nearly all, the sepals marks of the rosy purple colour from the front of the lip.—J. D.

Cattleya Trianae and C. Percivaliana.—Many fine specimens of these two beautiful *Cattleyas* are now in great beauty in Mr. Jacomb's collection at Stamford Hill. They have been flowering since Christmas, and before their blooms fade other varieties of *Trianae* will be open. These will bridge over the time until specimens of *C. Skinneri* and *C. Mendelii* open their flowers. They are grown in a moderate and enjoyable temperature, and are not drenched with water, a state in which many keep their plants, though such treatment results in disappointment.

Cattleya Warszewiczii superbissima.—This variety, now in flower in the collection of Mr. De B. Crawshaw, at Sevenoaks, has also a slight stain of yellow on the sepals, but not to the extent of Mr. Vanner's plant. The sepals and petals are of a very soft rosy tint. The lip, too, is rose-coloured, with a yellow stain in the throat. The flowers, which are well formed, measure quite 8½ inches across. The petals are 2½ inches by 1½ inches. The true *C. Warszewiczii* delicate is also in flower in Mr. Crawshaw's collection. It is a very pretty form, but bears no comparison with the variety first named.—J. D.

Trichoglottis fasciata.—This rare and curious plant somewhat resembles in appearance and habit of growth *Benanthera coccinea*, but it is said to be nearly related to the genus *Phalenopsis*. Its racemes, which are lateral, each bear some four flowers, measuring about 2 inches in diameter. Their sepals and petals, which are nearly equal in size, are greenish yellow transversely banded with reddish brown. The three-lobed lip is white, tinged with mauve, and bears a few spots of brown near the edges; a pair of blunt, horn-like appendages stand out at right angles from the base of the front lobe. It is a native of the Malay Islands. We recently noticed this remarkable Orchid in flower in Sir Trevor Lawrence's garden at Dorking.

Rating nursery ground.—A short time ago the district in which I am located was, by an extension of the boundary, enclosed in the borough of Bury. This, of course, has put me under a different system of rating. I have just had a general rate sent in to me, in which the authorities seek to charge me on the full annual value; whereas, as I

understand, nursery grounds, market gardens, and agricultural land are all rated at only one-fourth their annual value. Before contesting the point, I should like, if possible, to ascertain whether my supposition is correct, and I should esteem it a favour if any of the readers of THE GARDEN can afford me any information on the point.—C. A.

NOTES OF THE WEEK.

We have received from the director of the Royal Gardens, Kew, a very comprehensive list of the seeds of hardy annual and perennial plants grown in that establishment.

Spring flowers from Cork.—We have received from Mr. Hartland two small bouquets from the outdoor garden, consisting of *Grape Ilya* both and *Capax Dafodilli*, backed by a few sprays of an *Azara*—a charming combination; also his first bloom of *Narcissus Horsfieldi* from the open border. *Capax* is quite a gem in the way of early *Dafodilli*—pale yellow and sufficiently double without being formal.

Clerodendron fragrans.—This stove plant is not remarkable for brightness of colour, but the fragrance of its clusters of white-pink-centred flowers renders it a desirable plant to grow for winter bloom. There is a double variety of it, but this is not more fragrant, though perhaps showier and more persistent in bloom. Both are in flower in the stoves at Kew.

Dichorisandra cuprea.—This is an ornamental-leaved member of the genus *Dichorisandra*, most of which have either blue or violet coloured flowers, and are natives of Brazil. They belong to the Spiderwort family (*Commelynaceae*), of which *Tradescantia* is a familiar example. The leaves are lanceolate-acuminate, buff-coloured, and ornamented with a broad central stripe of purplish black, which traverses the entire length from base to apex. It may now be seen in one of the stoves at Kew.

Restio subverticillata.—This is the name given to a very curious tree-rush-like plant of handsome appearance, which is now in flower in the Cactus house at Kew. It is some 4 feet in height, has dark green, much-branched, slender, rush-like stems, bearing upon the points racemes of flowers enclosed in long, dark brown bracts, which give the plant quite a unique and elegant appearance. It is a native of the Cape of Good Hope, where its stems are used for brooms, and it is also known by the name of *Willdenovia teres*.

Narcissus cyclamineus.—As noted by Mr. Englehart in last week's GARDEN, I find that seeds of *N. cyclamineus* planted the first week in July germinated the 1st of February, and all came up within a few days. I cannot understand why the desire is so great to find out its parentage. I cannot think either *triandrus* or pseudo-*Narcissus* have anything to do with it, as it has neither habit nor appearance of one or the other, and until some good reason is given let it remain what it professes to be—a long-lost species. It has been in flower now more than a month, and the blooms are as fresh as the day they first opened. I do not find the natural habitat of *pulchellus*. I have several kinds of *triandrus* of other than the type from Portugal, and possibly *pulchellus* may be amongst them, but they have not yet bloomed.—OCTAVIUS CORDER, *Norwich.*

Spring flowers at Kew.—The display of forced spring flowers and Cape and New Holland plants at Kew is just now very good, although we do not admire the system carried out there of grouping in families for effect. One of the great features in the greenhouse is the display of *Lachenalias*, which are admirably flowered, the principal kinds being *tricolor*, *pendula*, and *Nelsoni*, the latter having large tubes of a rich deep yellow. *Lachenalias* may be grown either in pots or in hanging baskets; they require a season of rest after the leaves are dead, and then they may be potted and started into growth from time to time as may be required. Their long spikes of tubular flowers are very conspicuous and last long in perfection, and, in addition to their blooms, the leaves of some of the kinds are beautifully variegated. The yellow *Primula floribunda* is neat and effective, whilst the bright yellow sprays of *Acacia linearis* and *leprosa* are very charming. Numerous well-bloomed plants of various sizes of *Azalea amoena* give a warmth of colour, which is toned down by various *Rhododendrons*, the most conspicuous amongst which are *præcox* and its variety *rubra* and *Countess of Haddington*. Of this latter kind, with its large bell-shaped blooms, one specimen alone bears several

hundred flowers. Intermixed with these were Cyclamens in endless shades of colour, numerous kinds of Eriostemons, Dentzias, Grevilleas, and Camellias. Amongst the latter we noticed a well-flowered specimen of the old-fashioned reticulata, a magnificent plant of which exists in a Thames-side garden close by at Ilam. Epaerises were plentiful, their waxy tubular flowers varying from pure white, through all shades of rose, pink, and red, up to brilliant scarlet. Cinerarias in various shades and well bloomed are always welcome at this season; as are also the bright colours and agreeable perfume of Hyacinths. With these were associated Tulips and such like plants; also various kinds of Indian Azaleas, Eupatoriums, Callas, and numbers of Rhododendrons of the jasminiflorum section.

Narcissus Ard-Bigh (Irish King).—I received bulbs of this last autumn from Mr. Hartland, Cork, and it is so distinct, that I offer a few remarks about it. Planted on the same day with pallidus præcox and kept in a cold house, it has bloomed a week earlier. It is a very fine form, quite as large as Emperor, but much more robust and taller; the trumpet and perianth are both of a deeper colour, the leaves very stiff, and of a rich glaucous green. Its early and very free flowering, robust habit and general appearance will command attention and appreciation wherever it is introduced.—OCTAVIUS CORDER, *Norwich*.

The proposed gardeners' orphanage.—I am desired to state that, as soon as arrangements can be made, a meeting of gardeners and others who have signified their interest and approval of the proposition to establish a gardeners' orphanage or fund for the orphan children of gardeners will be held in London, to discuss the matter generally, and to take what steps may seem necessary in furtherance of the objects in view. In the meantime, it would facilitate matters greatly if those who are disposed to support the proposition would kindly send in their names, with any suggestions on the subject they may be pleased to submit, either to Mr. C. Penny, The Gardens, Sandiogh, King's Lynn, or to Mr. A. F. Barron, Royal Horticultural Society, Chiswick, Secretary *pro tem*.

Bentham's Cypress.—There are not many tender Conifers worth growing in pots in cool green-houses, but *Cupressus Benthami* is certainly suitable for that treatment, as it is a most elegant pot plant, and at this season, when in flower, particularly attractive. There is now a plant of it in the temperate house at Kew about 5 feet high, bearing such a profusion of its tiny catkins, that it looks at a distance more like one of the Acacias. These cones of pollen-flowers are borne at the tips of the branchlets, and are of a pale fawn colour. The branches are long, very slender, and the twigs droop in a graceful way. It is a Mexican tree, growing on the mountains to as much as 60 feet high. It is quite a tender plant in this country, but for the sake of its elegance it is as worthy of pot culture as the Australian Araucarias.

Violets from Ireland.—In the last issue of THE GARDEN, mention of some fine Marie Louise and Comte de Brazza Violets being sent to you from the Cotswold Hills tempts me to send you some for comparison from the west of Ireland. I am also anxious you should see a kind I send, which is very like the Marie Louise, only a good many shades lighter in colour, and without the red in the centre. I had a few plants of Marie Louise left in a bed of Neapolitans, and after a year or so I found the plants in question, which I believe to be a cross between the two kinds. I took them up (the two or three plants) and kept them carefully apart, and they have remained quite true. I have a large frameful of them now, and they are to my mind more lovely than any other sort I have seen. I also send you some single Anemones, the seed of which I sowed last April. They flowered by the 1st of October, and have been in bloom ever since, frost and snow not seeming to dismay them in the least. I never had single Anemones do so well or blossom so constantly and profusely in mid-winter before. I may add that I have Marie Louise Violets blooming profusely on a north border without any protection. They have been in bloom since September last, but during frost and snow for about ten days they did not show much bloom. The Violets I send are all from cold frames, in rather an

exposed situation. Neapolitans bloom very well here planted under a south wall between fruit trees.—MRS. PERY, *Coolcronan, Ballina, Co. Mayo*.

* * A beautiful gathering of Violets, consisting of Neapolitan, Marie Louise, Comte de Brazza, and Coolcronan Hybrid, said to be a cross between Marie Louise and Neapolitan. The new variety is paler in colour than Marie Louise; the flowers are larger and better than those of the Neapolitan. There were also sent some very fine single Anemone flowers, showing that the climate suits them.—ED.

Isotoma hirsuta is a plant not without considerable value as a winter-flowering plant in a stove, and single blooms of it cut and arranged in the foliage make charming small bouquets, as the stalks are long and slender. It has a Gesneria-like flower, or rather like a small Foxglove; the colour is a glowing scarlet, and entirely covered with a velvety down. It is inclined to be straggling in growth, but this may be corrected by due attention to pinching and pruning. It is quite a stove plant, delighting in a warm and moist house, and it is in bloom now at Kew, and has been for several weeks past.

Corylopsis himalayana.—This extremely rare shrub is now in flower in the temperate house at Kew. It is a pretty and most interesting shrub, and a good deal like the commoner *C. spicata*, a Japanese species introduced about twenty years ago. *C. himalayana*, as its name implies, a native of Northern India, being found in the Khasya Hills and Bhotan, growing at from 4000 feet to 8000 feet above the sea-level. It may, therefore, prove as hardy as the Japanese species, though on account of its rarity it is not risked in the open-air collection at Kew. As in the rest of the species, it is leafless at flowering time. The flowers are produced in dense drooping spikes about 2 inches long. Their colour as well as the bracts is pale yellow and the flowers fragrant. The leaves are some 4 inches or more in length, roundish, and with prominent veins. There are but four species of *Corylopsis*, these being *C. spicata* and *pauciflora*, both from Japan, *C. multiflora*, a native of China, and *C. himalayana*. The genus *Corylopsis* is allied to *Hamamelis*, *Parrotia*, and *Fothergilla*, and the name was given on account of the resemblance in the growth of the shrub to the Hazel-nut (*Corylus*), but the similarity ends there.

Royal Horticultural Society.—At a meeting of the council of this society, held on the 8th inst., a draft memorial for submission to the Queen was read, and Sir Trevor Lawrence was requested to lay the same before Her Majesty at an early date. The memorial briefly reviews the history of the society since its foundation in 1804, and, after setting forth its intimate and influential connection with the progress of practical and scientific horticulture, refers to the beneficent influence which the late Prince Consort exerted over its fortunes, which have steadily declined since the removal by death of His Royal Highness from the presidency of the society, until in 1882, after years of continually increasing financial difficulties, the society, being unable to carry out the terms of its agreement with the 1851 exhibition commissioners, was compelled to give up possession of the gardens, and is now brought face to face with the grave problem, not only of how its future work is to be carried on, but even as to how its existence is to be maintained. The memorial, after alluding to the prestige of the society at home and abroad, prays Her Majesty to use her influence to obtain for the society a sufficient portion of ground on the South Kensington estate for a building to accommodate its committees, its valuable library, and its offices, together with the use of the conservatory and quadrants in which to hold its shows. The memorial, moreover, assures Her Majesty that the council of the society approach her with the hearty concurrence and support of the most eminent horticulturists of the kingdom, both amateur and professional, and in the firm conviction that force is added to their appeal, not only from the past history of the society, but also from the fact that the sphere and scope of its work are distinctly germane to the objects for which the land at South Kensington was bought.

Azaleas.—I am in trouble about my Azaleas, of which I have a fine collection. They have done well for some years past, and until lately. I am told that the cause of their look-

ing so badly is the water (given them during the drought of last summer), which is strongly impregnated with lime. The opinion and advice of some of your readers on the subject will oblige, as I fear I shall lose some valuable plants.—W. E. E.

Horticultural club.—At the last monthly meeting of this club, held on March 8, the usual discussion was opened by Dr. Masters, who alluded to the history and development of the Chinese Primrose as affording a remarkable illustration of the phenomena of variation independent of those produced by cross-breeding or hybridisation. The presumed causes and significance of variations were briefly alluded to. Some of the variations were apparently due to excessive or to diminished heat, light, or food supplies; others to reversion to a primitive ancestral state, presumptive evidence of which latter is derived from an examination of the course of development of the seedling plant. That hybridisation had played no part, in recent times at least, was shown by the fact that until lately the wild form of the plant was not known, and, moreover, that all attempts to cross-fertilise the Chinese Primroses with pollen from other species had hitherto failed. The plant as first introduced to this country was a cultivated form, which immediately manifested a tendency to vary, and in practice it was always grown as an annual. During the last few years, however, the true wild species had been found in the mountains of Y-Chang, in Central China, by several collectors, growing on bare limestone rocks, exposed to the sun, and with but a scanty supply of water. It is a perennial with a thick, woody, branching rootstock, covered with the remains of former leaves, and with an internal construction different from that of any known Primrose.

Daffodils.—Will anyone who has *Narcissus poeticus ornatus* now flowering in pots kindly send me a flower with pollen for hybridising?—G. H. ENGLEHART, *Applethorpe, Lincoln*.

Comte de Brazza Violet.—I send you two plants and a few flowers of Comte de Brazza Violet.—G. H. MORTONSON, *Lifton Park Gardens, Devonshire*.

* * Well-grown examples, healthy and bristling with flowers of large size.—ED.

MR. WILLIAM PAUL, of Waltham Cross, is announced to read a paper on "The Ancient and Modern Literature of Gardening" before the Royal Society of Literature, 21, Delfay Street, St. James's Park, on Wednesday, the 23rd of March, at 8 p.m.

Cyclamens.—From Messrs. Page and Sons, Teddington, we have received flowers of their strain of Cyclamens, the blooms of which are large and fine, and range from pure white to purple. In our notice of the last meeting at South Kensington, Messrs. Page and Sons were inadvertently alluded to as Messrs. Pope and Son, Twickenham.

Names of plants.—*Ancious*.—1, *Odontoglossum Edwardsii*; 2, *Hestrepia antennifera*; 3, *Laelia harpophylla*.—*Mascarene*.—1, *Angraecum Leonis*; 2, *Phajus irroratus*, pale variety; 3, *A. glaucum virens*.—*H. J.*, *Nottingham*.—1, *Lycaste piana*, typical form.—*J. C.*, *Try Bride*.—1, *Cornus* sp., cannot name without flowers; 2, *Jasminum revolutum*; *Camellia*, cannot identify; send again.—*G. S.*, *Scapularis*.—1, *Lachenalia glauca*.—*W. Sutton*.—*Myrsiphyllum asparagoides*.—*H. E.*—1, *Etonymus radicans*; 2, *Berberis stenophylla*.—*A. C.*—*Dendrobium bigibulum*, small flower, but very highly coloured.—*A. W.* (*Birmingham*).—Your flower is a very good form of the typical *Odontoglossum maculatum*.—*A. J.* (*Dunstable*).—The orchid flower is probably a form of *Maxillaria variabilis*; specimen insufficient.—*T. J.* (*Sunderich*).—1, *Trichomanes anceps*; 2, *Feca spicata*; 3, *Elaphoglossum Herminieri*; yes; all are found in Trinidad.—*Empireur*.—1, *Maxillaria grandiflora*; 2, *Oncidium cucullatum*; 3, *O. flexuosum*.—*Australia*.—1, *Eriostemon cuspidatum*; 2, *Epacris onomatocora*; 3, *Grevillea ericifolia*; 4, *Acacia lineata*.—*E. W. E.*—1, *Iris fimbriata*; 2, *Euphorbia Begeri*; 3, *Behnia reticulata*.—*H. W.* (*Southern*).—1, *Colax jugosus*; 2, *Oncidium sarcodeis*; 3, *Dendrobium luteolum*; 4, *Dendrobium nobile*, very dark form.—*A. J.* (*Manchester*).—From the second specimen of your Orchid, with imperfect description, we imagine it to be *Dendrobium speciosum*.—*T. H.* (*Norwich*).—1, *Correa speciosa*; 2, *Hemantthus natalensis*; 3, *Cyrtanthus Mackenii*.—*J. Simpkins*—*Steriphoma paradoxa*.—*J. FORESTRY NOTES.

TRENCHING FIR PLANTATIONS.—To anyone in the position of "S. N.," who inquires if this should be done, the answer is, most assuredly, "Don't," unless expense is no object. It will not pay to trench for timber in this country. Draining is needful in some cases, but that is all. We are aware that trenching has been adopted on some estates by foresters who do not appear to have calculated the loss which it entailed, but it is not justifiable, save under exceptional circumstances. The way trees will grow in apparently poor ground is wonderful, and ordinary trenching hardly affects them, because the roots penetrate the subsoil chiefly. We could name extensive tracts of shallow soil lying upon rock or poor, yellow brash that have produced good and large Oak for hundreds of years, as well as other trees, and yielded many thousands of pounds' worth of timber to the proprietor, and which at the present time promise to produce even better Sycamores and Firs, with which the Oaks are being superseded. Those who trench extensively will never get their money back. Whether trees will grow well in the natural soil or not can generally be easily ascertained, because there are sure to be some trees in the neighbourhood growing in the same soil, and the way they behave will always be a safe guide to any planter, only he must be careful to allow for exposure, prevailing winds, and other climatal conditions that have often far more to do with the quality of the timber produced than the soil. The best and deepest soils, of course, produce the finest trees, but good forestry in this country consists in producing timber in soils and situations that cannot be profitably put to any other use. This is really making two blades of Grass grow where one grew before, and there is plenty of scope for work of this kind.

CONFLICTING TESTIMONY ON THINNING PLANTATIONS.—Writing on thick and thin planting last week in a contemporary, Mr. A. D. Webster says, very rightly, that "where the production of timber is the main consideration, then, by all means, but particularly in Pine plantations, preserve an unbroken leaf canopy, for by so doing the tallest and cleanest timber will be produced." Mr. Webster has considerable experience, I believe, and I am sure he is right in this matter, but here is the testimony of another forester of over "forty years' experience" given in a paper read at the International Forestry Exhibition, Edinburgh, by Mr. Baty, of Netherby Hall, and distributed not long since in a pamphlet form among foresters: "Not much thinning," this writer says, "will be required the first ten years . . . but after that time the cutting out process must begin. It is now of the utmost importance to thin by carefully cutting out the worst trees, and allowing the free circulation of light and air to penetrate through the whole plantation. This should be continued at stated intervals of four or five years up till thirty years of age . . . and at intervals up till sixty years of age, when more cannot be done till they are finally cut down." To permit a free circulation of light and air to every part of the trees till they are sixty years of age or fit to fell is just the opposite of preserving an "unbroken leaf canopy," which means excluding the light and air from the trunks. Mr. Baty's way is the way to grow useless branches and knotty useless trunks, that render timber unsaleable, and Mr. Webster's method is the way to grow good timber. But it is the conflicting testimony on this subject by foresters of mature age that I would dwell upon, as showing how little the teachings of some writers of professed experience are to be relied upon. It would pay proprietors well, whose woods are thinned on Mr. Baty's principle, to have a score or two of Norway poles and Baltic logs set up on end on their estates as close together as they grew when alive just to show their woodmen of the

rule-of-thumb order how good timber is really produced. Mr. Baty's teachings corroborate all I have said lately of the extravagant extent to which thinning is carried in the north, and the utter waste it entails. It is safe to assert that on estates where the trees have been periodically thinned on the principle of allowing the air and light to penetrate every part, the wood cannot be of as good quality as it ought to be or might have been, because the principle is wrong to commence with, and the practice resulting from it wholly inimical to the production of good timber, and utterly opposed to those conditions of growth under which the fine, clean, straight timber is produced abroad that is imported so extensively to this country. In these countries Mr. Baty's periodical thinnings would be simply ignored, however they may have been received at the Forestry Exhibition, where, in my opinion, such recommendations could only do harm.

THE PRIVETS.—I see the oval-leaved Privet is highly praised by Mr. A. D. Webster, and it deserves praise. It is a wonder to me that neither the old nor the new variety, the narrow-leaved and the broad-leaved, have been used for hedges to any extent worth speaking of. I doubt if the oval-leaved be superior to the narrow-leaved for such a purpose. Branchy, spreading shrubs always make the best hedges, because they fill up from the bottom, and there can be no doubt about the narrow-leaved common Privet being the best in that respect. The oval-leaved kind grows very erect. In an extensive covert not far from here, planted almost exclusively with both sorts, the oval leaved variety is conspicuous by its habit, but the common Privet makes by far the best covert. We propagate both extensively, and for the last month we have been planting or filling up fences with both mixed. The taller oval-leaved kind gives height, and the common kind ensures density. But the last alone makes a tall, close hedge. A friend of mine has his garden fenced off from the road by a hedge of it that has been full grown for probably twenty years: it is about 9 feet high, and dense and close right to the ground at the present time—the best hedge I know of—but it has been regularly clipped. Visitors to Scarborough cannot fail being struck by the extensive plantations of the oval-leaved Privet everywhere in the suburbs of that town, and in some places close to the sea. I have never seen Privet so green and pretty as there; in fact, it seems to be about the only shrub that thrives well on that cold coast so destitute of vegetation compared with the west coast. As to the hardness of the Privet, our plantations in the open nursery always get severely singed by sharp frosts, but in woods it does not suffer so much.

Choice Hollies.—Mr. Coleman's list of choice Hollies (p. 246) does not include, I hope, all that he considers choice, and I presume he only includes the species as distinct from the many varieties of the common *Ilex Aquifolium*. I am pleased to see that the noble-leaved *I. latifolia* succeeds well at Eastnor, but it cannot be called satisfactory everywhere. Even about London, and the south of it, it is not a plant to be trusted away from a wall, yet, on the other hand, I have seen a large-headed tree of it in Gloucestershire. Has Mr. Coleman tried out of doors the other large-leaved Holly, *I. insignis*, which is even handsomer than *latifolia* on account of its gophered leaves? *I. cornuta* is another species I have always had the impression is not worth planting, but after the hints of Mr. Coleman I shall not give it up. The two names *I. balearica* and *maderiensis* appear to be mixed in nurseries. What is often labelled *maderiensis* is certainly only a variety of the common Holly, while the true *Minorca* Holly (*I. balearica*) is a very distinct plant, and is the same as the *I. maderiensis* of Willdenow, but the *I. maderiensis* of Lamarck as I know it is quite a tender plant. Mr. Coleman may like to know that there is a robust-growing variety of the pretty Japanese *I. crenata* which has broader leaves, and is altogether a larger-growing shrub; it is called *latifolia*. *I. Dahoon*, an American Holly, is good in some places, and *I. opaca*

is another. Perhaps Mr. Coleman will say if these are growing at Eastnor.—W. G.

BEST SEASONS TO PLANT.

We do not believe in planting Conifers in summer, as advised by "E. D." (p. 224), and when I read on that "every tree was moved with balls of earth varying from a quarter to one ton in weight," I thought his examples of little value and far from the point. It is very well known that, given a sufficient ball of soil to a tree, you may transplant it at any time during the year on any soil without much, if any, risk; but when it comes to planting young trees in great variety, probably roughly removed from a strange nursery and planted by contract, then the question of the best season to plant becomes an important one, and I know nothing that says so little for our forestry practice as the fact that planters should still be at sixes and sevens on a subject that people could determine for themselves if they were but to notice for one or two years the behaviour of trees planted at different seasons. I do not believe the character of the soil has much, if anything, to do with the season of planting, because, according to what is known of plants and their roots, a tree that transplants well on heavy soil, say in October, ought to transplant in any other at the same time, and *vice versa*. The philosophy of planting is put in a nutshell by Lindley in one or two of his 286 physiological aphorisms in his "Descriptive Botany and Vegetable Physiology," a book far too little read and known among foresters. He writes: "Transplantations may take place at all seasons of the year, and under all circumstances, provided the spongioses (root points) are uninjured. But as it is impossible to take plants out of the earth without destroying or injuring the spongioses, the evil consequences of such accidents must be remedied by the hindrance of evaporation. Transplantation should therefore take place either when plants are torpid and when their respiratory organs (leaves) are absent, or, if they never lose those organs, as in the case of Evergreens, at seasons when the atmosphere is periodically charged with humidity for a considerable time, or else in the early autumn when the warm earth promotes the rapid renewal of such roots as may have been destroyed." The main causes of success and failure are here put clearly, and the question is, at what season of the year is least injury likely to be done by evaporation to the roots and branches, or to the roots by mutilation? The answer is, Decidedly when both are most active and tender, and that is in spring and summer. In spring the days are keen, cold, and draughty, and the injury to young trees lying about and not too carefully handled by the average workman when planting by the piece is often so great as to kill the trees. The greatest mortality I have ever seen among young trees happened under these conditions. Last year I was asked to look at a mixed plantation, the greater portion of which was dead, the circumstance being a mystery to the proprietor, and I learned that the trees had been put in two years before, during April, in droughty weather that continued a good while after the planting was finished, and as the trees now dead had apparently never made a start, there could be no doubt about the cause. Planted so late under such conditions the Corsican Fir is almost certain to die, unless planted direct from the home nursery and well watered. Planting in summer is, if anything, still worse in the case of forest trees generally, for then the tender young roots are easily injured, and evaporation is active from the budding shoots. The most favourable conditions for planting exist in autumn, from September till the middle of November. Then the roots are ripe and tough, the foliage of evergreen Firs, &c., also ripe, and the evaporation less active, deciduous trees perfectly safe to move, the soil warm enough to excite growth, and the air moist and genial, the consequence being that the trees are partly established before winter, and make a much better start and better growth the following season than do those planted in

winter or spring. This is so apparent to all in the case of deciduous trees and Firs that one wonders to hear of any doubts on the subject. A Sycamore, for example, planted just when its leaves are fading in autumn will make fair growth the next season, but if planted in spring will only make a few poor leaves. A year, indeed, is sometimes gained by autumn planting.

Uprooted trees—Within the policy grounds at least few things in connection with forest management, it must be admitted, have a more neglected-looking appearance than upturned trees, broken and twisted branches, and fresh transplants half-cut with the wind. The former in particular should never be tolerated in well-kept grounds, for as soon as convenient after a storm a general clearance should be set about, and be prosecuted with all vigour until the work is completed. First, attention should in all cases be directed to such trees as have fallen on or over the most public roads, and after that those nearest to and visible from drives and walks may be grubbed up, the stems removed, and the roots at once buried or otherwise disposed of. In most cases the easiest and cheapest method of disposing of such roots is to dig a hole of sufficient size immediately behind them, and into which they will fall when severed from the trunk. The hole should be dug of sufficient depth to admit of at least 2 feet in depth of soil being placed atop of the root, although in the case of worthless ground, or where other trees are not to take the place of those upturned, 6 inches to a foot of covering will be quite sufficient. Frequently when tree roots are in such positions that burying of them is, whether from cost or other causes, out of the question, we employ a low, four-wheeled truck with which to convey them to some out-of-the-way place reserved for such rubbish. All branches should either be carted off or burned up at once, the soil turned over by the tree-root levelled down, and the trunk or stem removed to the timber yard. The branches of adjoining trees that got damaged or broken off by the fallen timber should be pruned off, and the wounds caused by amputation dressed over with tar, or failing this, some damp soil rubbed over their surfaces, as such are very unsightly where visible from the main drives and walks.—A.

The Mountain Ash at home.—To see the Rowan tree, or Mountain Ash, in all its grandeur, one must ascend among the rocks and rubble of our wild mountain-sides, for there alone is its true nature really revealed to us. To see it cropping out from some of the nooks and crevices where there is hardly a particle of soil and covering, though in a semi-procumbent manner, several square yards of the rocky surface with its fresh, green, Fern-like foliage and clusters of conspicuous berries, is, in truth, a treat that one could hardly think of enjoying at such an altitude. Not many days ago I, out of curiosity, took the measurement of what I then considered an unusually fine specimen of the Rowan tree growing from a rocky ledge in the pass of Nant-Francon (pass of the beavers). The height to which this specimen had attained was nothing remarkable, but the stem girthed fully 8 feet, and the large umbrageous head covered a surface of 27 feet in diameter. It looked cheery and happy in its mountain solitude, its companions alone being a few stunted Birches, a nice green carpet of the Crowberry (*Empetrum nigrum*), and a big tuft that quite filled up a fissure in the rock of that pretty and desirable Everlasting, the Mountain Cudweed (*Antennaria dioica*). Somehow, I fancy, but only in judging from my own observations in this district, that the tree in question attains to larger dimensions at a moderate elevation than when grown even at sea-level; and, moreover, that in high-lying districts it grows more rapidly until full maturity is attained, produces a nicer and cleaner stem, and wood of better quality and larger size, than at lower levels.—D.

Vegetation of a mountain woodland.—The great difference between the natural underwood of a seaside plantation and that of a wood at 1000 feet altitude was never more forcibly brought under my notice than whilst thinning a rocky plantation at the latter height during the past summer. The wood in question is situated on the flank of one of the Snowdon

spurs, fully exposed to our dread south-western blasts, the lower portion being 700 feet and the topmost peak fully 950 feet above sea-level. The soil is a free, sandy loam, resting at a few feet depth on slate rock, but the latter crops up here and there all over the woodland, in some cases to such an extent as to quite monopolise the surface and prevent tree-growth. The largest and most aspiring of this natural mountain underwood is the Bilberry or Whortleberry (*Vaccinium Myrtillus*), a most useful woodland plant for the great shelter it affords to game, and, what is not one whit behind this, the great amount of food afforded by the berries to bird-life at high elevations. In the wood in question, but particularly the more open and rocky parts of it, this plant grows stout and long, some portions of the ground being so thickly overrun with it as to almost impede one's course. It forms a nice dry covert, of which hares and rabbits would seem to be particularly fond. Damper portions of the wood afforded another *Vaccinium* in the much-sought-after Cranberry (*V. Oxycoccos*), a plant the fruit of which is eagerly sought after by birds. Its low, wiry stems afford but small protection, however, to game; but it is certainly a pretty sight, with irresistible temptations, to see a Sphagnum-covered pool or boggy marsh, away near the hilltop, studded with the bright red berries of the plant in question. Some of the more open portions of the wood, but only at the higher elevations, are literally carpeted with that pretty and distinct plant, the Crowberry (*Empetrum nigrum*). Here, again, we have a valuable acquisition to our woodland plants, both in the warm carpet it affords and abundance of fruit produced, and of which game in general are particularly fond. All of these three plants just referred to are a source of profit to the farmers and cottagers of these mountain districts, for the fruit is collected by the careful and brought down to the nearest village or town, where they always find a ready market for preserves, &c. So plentiful were they during the past year that more than once I saw them offered at the low price of 4d. per quart in the village here. Heather, however, forms a large part of the natural herbage of the wood in question, and a valuable part it is for the shelter it affords to animal life generally. The Bracken, Bramble, Thorn, and Creeping Willow (*Salix repens*) are abundant, and contribute in no small degree to the richness of the underwood and general green appearance of the ground surface. As well as the plants just referred to, upwards of thirty-three others are found abundantly, but being of minute size, and consequently out of the drift of the subject under notice, we will pass them unnamed.—W.

An ornamental covert plant (*Spiraea Douglasii*)—Having procured a stock of this plant, increase by root extension is so rapid that one is frequently at a loss to know how to dispose of superfluous stock other than by reducing it to ashes or committing wholesale extravagance by pitching the plants on the rubbish heap. It may seem rather incredible to say that a *Spiraea* could afford shelter for game, but in the plant in question such is really the case, for the roots become so matted and such a dense growth of under-shoots comes up annually, that in suitable situations a by no means second-rate covert is produced. Apart altogether from its use in this way, this *Spiraea* is about one of the most ornamental flowering shrubs with which I am acquainted, the long spikes of pinky flowers having a very imposing effect where a quantity of the plants is massed together. If young plants are placed at a couple of feet apart in a rather free soil and open situation—the margin of a woodland is perhaps the most suitable place—they soon unite, the roots running very freely about and sending up strong shoots as they advance. The plant usually attains to 4 feet or 5 feet in height, and although deciduous, the rank undergrowth forms a warm and shady covering for ground game generally. Big, irregular shaped patches of the plant are shown off to great advantage in open parts of the wood margins, and where they are visible from roads and paths, for it is a pity to hide such a desirable, pretty, and free-flowering shrub. We cultivate a white-flowered form of this *Spiraea*, which is of equally rapid growth, quite as ornamental, and offers a rich contrast to the normal or pink form. It is best for appearance sake to grow these different coloured forms in

separate masses, for not till then is their decided and diversely coloured flowers fully appreciated.—A. D. WEBSTER.

Toughened timber.—By a new process white wood, according to the *Anglo-American Times*, can be made so tough as to require a chisel to split it. This result is obtained by steaming the timber and submitting it to end pressure, thus compressing the cells and fibres into a compact mass. It is the opinion of those who have experimented with the new process that wood can be compressed seventy-five per cent., and that some timber which is now considered unfit for use in such work as carriage-building could be made valuable for that purpose by this means.

Barking Oak.—No time should now be lost in making arrangements for barking Oak. All tools used at the work should be examined, and, where necessary, repaired, so that they may be ready when wanted. As bark-stripping is an operation that requires great vigilance on the part of the forester, in order to save it early without injury, he should have the trees marked and ready as a preliminary step to further operations. As a general rule early-saved bark is the best, and, if possible, it should be stripped off without hammering, as this bruises and lessens its tannin matter. As a general rule the trees will be ready for barking when the young leaves are expanding from the bud, but it frequently happens that trees in the same plantation are not all ready for barking at the same time; such as have the advantage of shelter and warmth will often part with the bark a week earlier than such as are growing along the margin on cold, exposed situations. Under such circumstances the better plan is to leave these to the last, when the bark can then be secured without hammering, which will save something in the shape of labour and expense, and add considerably to the quality and value of the bark when brought to market.—J. B. W.

Propagating *Cryptomeria elegans*.—In attempting to strike cuttings of this Conifer, I was not very successful when they were made from the current year's shoots alone and put in just as they had attained maturity, which is the most satisfactory system for the generality of coniferous plants. The way in which I struck great numbers of this *Cryptomeria* with scarcely any loss was to take good-sized cuttings and put them in a frame under a north wall. There they remained from the end of one summer to a corresponding period of the next before they were fit for removal, but as the cuttings were 8 inches or 9 inches long, they were as soon as rooted fair-sized plants. A frame such as that here mentioned under the shelter of a north wall is very useful for striking many things that root only with difficulty. My practice is to take out about a couple of feet of the ordinary soil and place a good layer of drainage material, in the shape of broken bricks, on the bottom, then fill up to the level of the surrounding ground with light sandy soil, pressed down firmly, the whole being finished with a slight layer of sand on the top. The bottom of the frame is just bedded in the soil to ensure its being air-tight, and it is then ready for the insertion of the cuttings. They are put in firmly and a good watering given, which under ordinary conditions will not need to be repeated for some time, as from its position the frame does not get any sun, and as the lights are kept close drying winds have but little effect. As soon as the cuttings are rooted sufficiently they are removed and the space is thus available for something else. In this way there is generally room for the insertion of two or three cuttings which otherwise would probably never be put in. If any signs of damp or decay show themselves a little air is given to dry up superfluous moisture. The best time to put in cuttings of Conifers is about August, just as the young growth has partially acquired a woody texture, and the same may be said of most other Evergreens, while deciduous subjects do best when put in during winter or early spring.—T.

The air of forests in summer is of a much lower temperature, less dry, and contains more ozone than that in the open. In winter, too, forests afford a protection against violent and bleak winds, and, from a sanitary point of view, Professor Ebermeyer considers the fragrance of leaves, and, in particular, the strong resinous odour of coniferous trees (such as the Firs and Pines), as very invigorating and healthful.

No. 801. SATURDAY, March 26, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature; change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

IN THE FORTUNATE ISLES.

FROM a gardening point of view, as well as from that which is termed picturesque, there are few places in the world that will so thoroughly repay a visit as these lovely islands. Placed almost on the verge of the Tropic, surrounded by sea, and bristling with mountains and forests in some cases, Nature has richly endowed them with flowers of unique interest and beauty. To begin with an island that has less charm at first sight than the rest, less us take the island of Grand Canary. The dry and hot breath of Africa that at times sweeps over the eastern shore of this island makes the coast near Las Palmas, its capital, look arid as an African shore; but once within the shelter of the first hills, what beauties of vegetation as well as surprises greet the wanderer!

All of us know the Date Palm (*Phoenix dactylifera*), with its grey-green foliage and generally sun-dried aspect, and some of us know in Rivieran gardens the young and vigorous plants of *Phoenix canariensis*, but no one, I think, can have any idea of the beauty of this island Palm until they have seen it here, where, of course, it can be found in all stages and sizes. Instead of a somewhat sparse head of leaves, more or less browned, the Canary Palm boasts an enormous crown of rich and glossy green leaves, that keep their verdure untarnished for years, so that on a well-grown specimen the size of head to that of the stem seems almost too big to withstand a storm; and yet these Palms perch themselves boldly on crags overlooking the sea, where every breeze must catch them. The rich groups of them in the valleys and by the roadsides are specially beautiful, though sometimes one sees a clump deprived of leaves or with heads tied up for blanching, as at Bordighera; but such is their vigour that they very soon push out new leaves and golden Dates. Here, however, comes a confession sad to relate—their fruit is dry and of no use for food, so the good folk of Canary no doubt some day will plant the useful instead of the beautiful Palm.

Climbing up the hillside, what quaint forms of vegetation greet the eye! First an Asparagus, with shrub-like growth and drooping branchlets covered with needle-shaped leaves and tiny white flower bells. Then comes a Dock, with woody stems that makes a handsome bush of 5 feet high or more, with bright green, oval leaves and creamy panicles of flower, which, in seed, turn to a bright red—a truly splendid relation of our Docks, surpassing even our giant, but coarse, *Rumex Hydrolapathum*. Surrounding the plots of Vines that are allowed to trail over the black volcanic ash, that in parts does duty for soil, are broad belts of common purple and white *Iris germanica* now in full flower, and here and everywhere the double *Pelargonium* is used as a hedge plant. It would be interesting to know where this plant really sprang from, because, though introduced if I mistake not to our gardens from Italy, it has been the common hedge plant here and at the Azores for many years. Perhaps, like other things, it has originated spontaneously in more than one spot. After these glowing colours, how quaint these gnarled *Euphorbia* bushes are, with their grey stems but thinly topped by bluish leaves and yellow-green

flowers, and, most of all, how absurd at first sight to see a whole field of Prickly Pear with each fat phyllode tied up carefully in white calico as if afraid of being sun-burnt. This delicate attention, however, is for the benefit of the cochineal insect, which is applied in this way to the Cactus leaves, as the eggs have been laid on these rags before they are tied on to the plants, when on hatching they at once fasten themselves on to the Cactus. This used to be a favourite industry, but the use of cheap aniline dyes has almost put a stop to the growth of cochineal, as the dried insect is now not worth much more than as many shillings an ounce as once it was worth pounds.

Climbing onwards and upwards on these volcanic slopes amid cinders and scorice, it is strange to observe the abundance of Hare's-foot Fern (*Davallia canariensis*), and a handsome but scentless *Cheilanthes* growing freely where any moisture may be found. On a steep slope facing north, where the dew lingers longest, vegetation becomes beautiful; the short turf is enamelled with the dainty white stars of two sorts of *Ronulea*, whose lilac and brown-tinted buds remind one of tiny Crocuses. Tall Canary Buttercups with pointed yellow petals, that lie flat out without any cup, are a very graceful variety of our homely *Ranunculus acris*, and in charming contrast appear fine masses of our cultivated *Cineraria vulgaris* here in its true home. No flower has gained less from cultivation than the *Cineraria*, for the growth and heads of bloom here are quite as large as those usually seen in pots, and the colouring of the blooms and their size vary extraordinarily from one place or island to another. It is really a beautiful sight to see these fine heads of flowers with such fresh leaves growing up among the bushes of white Broom (*Genista monosperma*), now covered with white blossom, or among the too ubiquitous scarlet *Geranium*. The Canarian form of the Butterfly Orchis is also abundant, but the flowers are rather greener and less sweet than the type; the two radical leaves also are pointed, while its habitat in the crevices or holes in the scorice is most remarkable, and makes one wonder if at home we give it sufficient drainage under cultivation. A curious Squill is very abundant, with lilac buds that open nearly white, but the petals are so short that this, at least, is not desirable as a garden plant. *Ferula tingitana* is abundant as we keep ascending, and its tall flower-stems crowned with rich yellow heads of flower are quite a feature on the mountain-side. *Briza maxima*, the big, trembling Grass, and an exceedingly pretty *Urtica* (?) with one-sided panicles, with pendent brush-like arms, predominate on the uppermost slopes, where purple Borage, yellow and white annual *Chrysanthemums* abound. But one solitary specimen of the Great Canarian Boragewort (*Echium simplex*) appears, and that as yet shows only its great rosette of silvery grey leaves, which presently will shoot up into a spike of white blossom 7 feet or 8 feet high. Just as the shrubby and perennial *Echium fastuosum*, with its sky-blue thyrses of bloom, is called Pride of Madeira, so may this giant white biennial form continue to be one of the many beauties of the Fortunate Isles.

The volcanic cinder crags are covered with various forms of *Sempervivums* and *Sedums*, whose fleshy rosettes of leaves or dainty rose and grey petals contrast very cheerfully with the black scorice, and *Cineraria maritima* and *Centaurea Clementei*, with silvery leaves and yellow flowers, overhang the very crater itself, where a yawning abyss, more than a thousand feet below, shows by its scorched rocks, still red, yellow, and

black, how violent must have been the eruption that excavated such a pit, and piled up on one rim of the crater such a mass of cinder that towers up 600 feet above that rim, and 1200 feet above the now level plain in the very centre of the crater.

Even in these latitudes the air is keen at this elevation, but as the Lentisk bushes and giant Fennel flowers are left behind us in our descent, so does the air feel less and less like the winter air of the Mediterranean shores; and ere we reach the glowing masses of *Bougainvillea* and *Cesalpinia* that overhang the garden walls of Las Palmas, we find ourselves again in summer.

E. H. WOODALL.

CHRYSANTHEMUMS.

E. MOLYNEUX.

IN all matters of detail in connection with *Chrysanthemums* it is wise to look ahead, and to push on little odd jobs whenever an opportunity occurs for so doing, in order that when the busy season sets in later on everything may be in readiness for it. Have, for instance, all pots clean and ready for use. Experience has taught me that, for convenience in housing, the size of the pot used is a consideration, because, where quantities of large blooms are required, large numbers of plants must be grown; therefore space in which to house such numbers has to be provided, and where room is limited it is a mistake to use large pots. Where one plant is grown in each pot, pots 9 inches in diameter answer admirably. This is large enough for any *Chrysanthemum*; for such pots, then, and for all other sizes, the plants must be prepared by previously keeping them in suitable pots, so that when the time comes round for the final shift the ball of soil may not be too large to be transferred to the pots in which the plants are to bloom without considerable reduction. This, of course, should not take place, as mangling the roots causes a serious check to the plants. The first shift out of the cutting pots should be into pots $3\frac{1}{2}$ inches wide; the next into $5\frac{1}{2}$ -inch pots, and from these the plants will go nicely into the 9-inch ones, which should be their last shift. Where pots of larger size are required, say 10-inch ones, the first shift may be into $4\frac{1}{2}$ -inch pots, next into $6\frac{1}{2}$, and then into the 10-inch ones. Again, it sometimes occurs that pots of a larger size are in stock, and must of necessity be used. If these are 11-inch ones, I prefer to place in each two plants, consisting of the weaker-growing kinds, and both should be of one sort, as if different one may outgrow its neighbour, and this may prove to be awkward at housing time, not only as regards appearance, but as respects the welfare of the dwaffer sort. By this mode of culture a great gain is effected, as nearly double the quantity of plants can be grown in the same space.

Chrysanthemum sports.—"G. H. E.'s" note (p. 212) on the simultaneous appearance of *Chrysanthemum* sports in different parts of the country opens up a very interesting subject, to which I have frequently directed attention. So prolific is the *Chrysanthemum* in the way of sports, that out of the first twelve in the selection of forty incurred exhibition varieties mentioned in Mr. Molyneux's book, five only are original seedlings. This is mainly due to the sportive character of *The Queen* family, one of the best types in the section to which it belongs. Many will doubtless recollect the confusion caused some sixteen or more years ago by the kinds named *White Queen*, *Empress of India*, *Lady St. Clare*, *Mrs. Cunningham*, *Snowball*, &c.—all no doubt sports from *Queen of England*, but not distinct from each other. Our leading trade growers and the National *Chrysanthemum* Society have set the matter right by making it more generally known that these are synonymous. In 1873, when Mr. C. Waters, of Forest Hill, fixed the Primrose sport of *Mrs. G. Rundle*, now named *George Glenny*, I saw it the same year in the gardens of Sir H. Peck at Wimbledon House.

Mr. Henderson, who was then gardener there, had a small specimen plant of Mrs. G. Rundle with half of the head of bloom primrose and the other half white. Two or three years later the same variety sported in two places to a deeper yellow, and the result was Mrs. Dixon and Golden George Glenny, which are synonymous. I think the variety Madame Martha sported in two places in the same season, and produced the golden variety. When Lady Slade produced Angelina I had the same sport on a plant the same season, but only very slightly, and consequently could not fix it. Madame C. Desgrange showed the same character, and produced the two yellow varieties named Golden Madame Desgrange and G. Wormig, which are identical. My sport from Prince Alfred, Lord Wolseley, showed itself in two places in the same season, but happily in close proximity to each other, and so by a little rearrangement, confusion in the names was saved. Baron de Prailly last season produced Carew Underwood in two places, and Ethel showed the yellowsport Mrs. Jones in three places to my knowledge. Last season I saw a streak of yellow in a bloom of Hero of Stoke Newington in one of the prize groups at Putney exhibition; therefore, I was quite prepared to see a yellow Princess Teck, from which the Hero is a sport, although I must acknowledge not so soon and so abundant as was demonstrated at the National Exhibition by blooms of Mrs. Norman Davis. I have had Barbara assume a chocolate colour, but could not fix it, and last year a bloom of Princess of Wales was brought to the Kingston exhibition partly yellow. These I am prepared to see established soon, and I have no doubt before long we shall have a deep yellow Empress of India. To what influences, it may be asked, are these changes attributable? We call them "freaks of Nature," but they appear to be produced by some natural law, which is well worth investigating.—C. ORCHARD, *Coombe Warren, Kingston-on-Thames.*

PROPAGATING.

GLOXINIAS.—Many cultivators now raise these plants from seed, and when it is saved from the finest varieties, the plants as a rule produce a good and varied lot of blooms. Still, this method cannot be employed for the increase of any particular varieties, and therefore, in order to multiply the many named kinds, other means have to be resorted to. The principal way of propagating Gloxinias, apart from seeds, is by means of leaf cuttings, as they succeed very well if placed under favourable conditions. The best mode of procedure is as follows: When the plants are growing freely (but as early in the season as possible) they may be looked over, and generally a leaf or two, or even more, can be spared from the base of the plant. The leaf should be separated as near the base of the stalk as possible, as, by so doing, the stalk is available for insertion in the soil. If the leaves are small, they can be allowed to remain entire, but in the case of large ones, they may be cut in two. Pots of 4 inches or 5 inches in diameter are a very convenient size for the cuttings, and are prepared for the reception thereof by draining them thoroughly with broken crocks, and filling them with light, sandy soil, sifted fine, leaving just enough space for a thin layer of silver sand on the top. The leaves are then dibbled in precisely as is done with cuttings of the shoots, and after being watered are placed, but not plunged, in bottom heat in a stove propagating case. So treated they soon root, and form a callus at the base of the leaf, from whence a shoot originates. As soon as any signs of this are visible, the cuttings must be potted off and grown on freely, in order to obtain as large tubers as possible before winter. Occasionally a tuber, instead of pushing up one stout shoot, will produce several small ones, and if they are taken off and inserted as cuttings, they soon strike and form plants. Seeds, from their minute character, should be sown very carefully, but, generally speaking, they germinate readily, and are not so delicate during their earlier stages as those of many other plants. Before sowing, the surface of the soil should be well moistened, as the seed then adheres readily thereto, when the covering may consist of the merest sprinkle of fine sand; or, instead of this, a pane of glass may be laid over the pot in order to prevent too rapid an

evaporation. In a general way the seedlings will soon need pricking off after they make their appearance above ground, and this is rather a delicate operation. The pots must be well drained, and the soil sifted fine and well watered before pricking off commences. To avoid handling the young plants, which are very fragile, a small piece of wood about the size of an ordinary penholder, with a cleft at one end, is very useful, as it can be worked with the left hand, and the young plants, being picked up with it, can be dropped into the hole, made by a dibber held in the right hand.

Other Gesneraceous plants, such as Achimenes, Tydas, and Gesneras, can be increased, when the plants are dormant, by division of the underground rhizomes. Besides this, should it be necessary to push on the propagation of any particular variety as fast as possible, the tops of the young plants may be taken off and put in as cuttings, when at this time of the year they root readily, and after flowering throughout the summer, will form good sized rhizomes by the winter.

CLEMATIS.—Stock plants of these that were taken into a slight warmth a few weeks ago will be by this time full of young shoots, and where it is intended to graft them, the present time is very suitable. The many beautiful garden varieties of this flower are generally increased by grafting the young growing shoots on pieces of the roots of the common Traveller's Joy, with which they readily unite. A shoot some inches in length may be cut up into several grafts for each scion need only consist of a single joint, with the piece of naked wood at the base thereof. This portion of the shoot below the buds is fashioned into the form of a wedge, and the selected root having been split for a short distance, the two are fitted together as accurately as possible, and tied securely, but gently, in position, with soft grafting cotton. After this is done the plants must be potted, using small pots for the purpose, and twisting the roots around in such a manner that the point of union is just covered with the soil. This being completed, the small plants must be placed in a close frame in the propagating house, kept at an intermediate temperature, when they soon form a union, and may then be gradually hardened off. If a number of them are grafted at the same time it is more than probable that some will be ready for removal much earlier than others, and, on that account, when they begin to grow (a proof that a union is effected) the whole of them had better be examined, and only those that are unmistakably united removed into more airy quarters. The string-like pieces of root intended as stocks should, if possible, have a few attendant fibres. This mode of increase is by no means the only one available for the different kinds of Clematis, as of the species seeds of many are often available, while all the garden varieties can be increased by cuttings as well as grafts. To strike the Clematis from cuttings, the young shoots should be drawn out in a gentle heat, as above recommended, for grafting, and being cut into convenient lengths, dibbled in around the edge of a 4-inch pot. The soil should be of a very sandy nature, and passed through a fine sieve, while the pots must be well drained. When watered the cuttings must be kept close till rooted, after the manner recommended for grafts, and so treated they will soon strike. Though it is quite as well to leave a joint at the base of the cutting, such a course is by no means absolutely necessary, and in the case of any choice kind as many cuttings may be made as there are joints on the shoot. In keeping cuttings close it does not imply that they are to be absolutely kept from contact with the air, for however delicate they may be, it is generally possible to take off the lights for an hour or so in the morning without causing even the most tender plants to droop. Of course this will to a great extent depend upon the mode of heating the propagating house and other conditions, as if the atmosphere be very dry the cuttings are soon liable to flag if exposed to it, while if very moist, mildew and decay are apt to follow. Shading, which can be dispensed with during the winter months, even for cuttings, will now need careful attention, as an hour's exposure to sunshine will often cause them to flag to such an extent that they do not quickly recover.

CANTUA DEPENDENS and the other members of the genus have the reputation of being not only difficult plants to grow and flower well, but also to increase by means of cuttings. Propagation of them is easily effected, provided a certain mode of procedure is carried out. In my case, having a few plants in 4-inch pots that had been wintered with the stock plants of Fuchsias and similar things, I took them into heat in the same manner as their associates, in order to draw out the young, soft shoots. These, when taken off, formed into cuttings, and, after insertion, kept close till rooted, soon commenced to grow, and in a month were ready to pot off. The principal care needed when in heat is to see that red spider does not effect a lodgment on the leaves.

ARAUCARIAS of the greenhouse class are generally propagated from cuttings, for even if seeds are available, plants raised in this manner are apt to be thin and naked at the bottom. In the case of cuttings, it is evident that as the beauty of a plant depends upon its symmetrical character the only cutting on a specimen that is of any use is the top. This should be taken off and potted in a mixture of loam, peat, and silver sand, with a little powdered charcoal mixed with the soil. The pot should not be too large, while the depth at which the cutting must be inserted to hold it in position will prevent the use of many crocks. Large cuttings cannot be depended upon to root; indeed, the weaker the cutting is the greater are the chances in favour of its rooting. After the head of a plant has been removed two or three leading shoots are generally pushed up, and when large enough they are all available for cuttings. If these shoots are taken off others will in time be produced, which in their turn can be removed; indeed, in nurseries where Araucarias are propagated largely these old stock plants are kept year after year and yield a great number of cuttings. These remarks apply more particularly to Araucaria excelsa, which is the easiest to strike and the most commonly grown of the greenhouse kinds. When seeds are obtained they do well sown singly in small pots, and shifted on as required. The seeds should be covered with about half an inch of soil. T.

PROPAGATING DOUBLE WHITE PRIMULAS.

EVERYONE conversant with market plants must be aware of the value of the old double white Primula in a cut state. Of all the new double forms raised during the past twenty-five years nothing produced can equal this variety for cut purposes, as with proper management it can be had in flower nine and ten months in the year. Some growers who make a speciality of this Primula grow large quantities, from 3000 to 5000 plants, and the propagation of this number is a work requiring considerable time and care. Mr. W. Elphinstone, of Shipley Hall Gardens, near Derby, who is a successful grower and exhibitor of double Chinese Primroses, sprinkles fine charcoal on the surface soil in which his plants grow, doing this when the plants have just gone out of bloom, and when they can be dried off for propagating purposes. He then cuts half-way through the stem of the shoot, causing it to fall down upon the charcoal; gradually the severed parts become callused, and they put forth roots, and when this latter takes place they are removed from the plants, potted, and grown on into size. Calling upon Mr. George Stevens, the St. John's Nursery, Putney, the other day, I saw that this grower, who produces some 3000 plants annually, had hit upon an excellent method of propagation which saves an immense deal of trouble. He grows his plants mainly in 4½-inch pots, a few being in 6-inch pots, and about April the surface is filled up with fine Cocoa-nut fibre, piled up in a little heap, and so covering the stems of the plants. The fibre is kept moist by being occasionally sprinkled with water. In a short time every stem puts forth roots into the fibre, and when this has taken place a sharp knife separates them from the main stem close to the soil. Having masses of little fibrous roots, they are then potted into large 3 inch or 4½-inch pots, and soon become established, and scarcely cease flowering, and as in Mr. Elphinstone's case there is but very little check. There is another point; the method of propagation as adopted at Putney does not need any sacrifice of the head of bloom, which goes on, and it

may be said with much truth that the plants bear flowers nine or ten months in the year.

Here, then, is a method of propagation that many gardeners might follow with advantage. I know that some of them, through lack of proper accommodation, find considerable difficulty in propagating the double *Primula* when following upon the old lines, but in the case of the newer and not less successful method it can be pursued under much less difficulty and with greater certainty of success. R. D.

LETTER FROM BURGHEY. TO THE EDITOR OF THE GARDEN.

SIR,—I have just had a charming walk round our garden this glorious morning. The sun is shining brilliantly, and the air is sharp, serene, and most enjoyable. I first came to our house of Tomatoes, which we struck last September and wintered in 3-inch pots; they are full of fine healthy spikes of flowers, setting admirably close to the pot. We grow them in 8-inch pots; some growers prefer 11-inch and 12-inch ones, but we have more faith in a potful of roots than soil: we therefore use small pots. Walking on, I come to our Carnation house, and here I look with admiration on my good friend, Miss Jollif, now in all her beauty, thinking to myself, if my practice is faulty, I at least am satisfied. No 8-inch pots are used in this case—only half-a-dozen by way of trial; but the least said about them the better. Depend upon it, all forced garden produce should have the roots restricted. "A wee drop of the cratur," in the shape of manure water, beats big pots, saves a deal of space and much heavy labour. Five-inch pots are my favourite ones; still, we have numbers of Carnations growing in 4½-inch pots, and very nice little plants they are. Extending my walk, I come to what may be justly called the kitchen garden conservatory, a whole range of Peach houses, with the trees one sheet of pretty pink blossoms—a sight indeed to behold. The bees are busy among them, doubtless thanking us for an early treat of nectar. And now I enter that part of our garden that lies nearest to my heart, viz., the kitchen garden. Oh, how bare and dejected it looks! The severe winter has killed my Spinach, which I never remember its doing before. We want a hardy Spinach badly. Last autumn I planted a large plot of Old King Henry; but his majesty is still sleeping—not an eye can be seen showing through the soil. How different, how pleasing, when I came to my good support, the Jubilee Green, which absolutely enjoys these frosty nights. It stands erect before me, peaceful and happy. What a comparison between my own Jubilee and the Queen's Jubilee! The latter takes up columns of the newspapers with perplexed ideas—newly-born crotchets that, I fear, will never be realised; but the former bides its time and will make its own way. Standing yet still, I hear one of my little olive branches announce that dinner is ready, and that mother has cooked The Dean Potato, which I hope to tell about next week. R. GILBERT.

The Rose of Sharon.—My attention has been drawn to an interesting article in your paper on the Rose of Sharon, which recently appeared from the pen of Mr. Newberry. I fear that the identification of the scriptural Rose of Sharon must ever remain a matter of speculation. But of one thing I feel certain, that it could never have been the *Nelumbium speciosum*. Theophrastus states that the *Nelumbium* grew in Syria. But Palestine is not Syria, only a small portion of that region, and there are districts in Northern Syria, e.g., the neighbourhood of the Bahr el Abiad and Antioch, well suited for this plant, though it is not now found there. But in Palestine there are only one or two small and secluded spots where it could ever have existed, viz., the little marsh at the head of the Zerka under the S.E. corner of Carmel, and the marshes of Huleh (Merom) under Mount Hermon. The course of the Jordan south of Huleh has no marshes. It is a deep, rapidly flowing stream, with frequent periodical floods and lofty banks everywhere. All the other streams, except the Kishon, are mere mountain torrents dashing through rocky gorges, and along the Kishon there are no suitable localities. It is impossible to believe that a plant which could only exist in one or two distant habitats could ever have been familiar to the Jews, nor is it likely that it should have become exterminated. As to Egypt, it would be difficult to find two neighbouring countries more utterly distinct in their physical character and botany than the valley of the Nile and Palestine. As to the other claimants, the Daisy (*Bellis perennis*) is not found in Palestine; the wild Rose is confined to the hilly north, and then only occa-

sional. The autumn Crocus is not characteristic, but the *Polyanthus Narcissus* is common and universal, and is still the favourite flower for its perfume, both of the town-people and the fellahin, who habitually during the season wear it in their head-dress.—H. B. TRISTRAM, *Colley, Durham*.

NOTES OF THE WEEK.

We have received from Mr. Moore, Curator, Botanic Gardens, Glasnevin, a comprehensive list of the seeds which they have there available for exchange.

We have received from the Secretary of the Royal Horticultural Society a copy of the report compiled by the Rev. G. Henslow, giving details of the effects of the severe frosts on vegetation during the winters of 1879-80 and 1880-81.

Lonicera sempervirens minor.—Mr. Chapman, gardener to Mr. A. Holford, Westcliff, writes to say that the above trained to the roof of a cool conservatory is now bearing hundreds of its beautiful flowers.

Narcissi from Ireland.—Mr. W. B. Hurland, Cork, sends us a very pretty gathering from the open air of the above, consisting of the following varieties, viz.: Ard-Kigh, from bulbs planted the first week in December; Golden Princess, fine; Tunist, similar to the last-named, but with shorter trumpet and perianth; and Leda.

Beaumontia grandiflora.—This beautiful plant is now in fine condition in the gardens of Earl Cowper, at Panshanger House, Hertford, where it covers the greater part of a greenhouse, and is now bearing nearly 200 of its beautiful trusses of bell-shaped flowers. Some of the trusses have as many as fifty expanded blooms.

Thyracanthus Schomburgkianus.—This old inhabitant of our plant stoves is one of the most graceful and attractive of soft-wooded, winter-flowering plants. It is an erect, slender-growing plant which attains a height of several feet, and bears ample oblong-lanceolate dark green leaves. The scarlet, tubular flowers are borne in long, pendent racemes from 2 feet to 3 feet in length, and produced in great profusion. It is also known by the name of *T. rutilans*. This plant is at present in grand condition in the gardens at Burford Lodge.

Cochliostema Jacobianum.—This is a handsome, but somewhat large-growing member of the Spider-wort family. It produces large oblong-lanceolate leaves, from 1 foot to 3 feet in length and some 6 inches in breadth. They are bright green edged with purple, sheathing at the base, and arranged in a vase-like manner; panicles lateral, much-branched, and ornamented with numerous large, deep, mauve-coloured bracts, the flowers themselves being blue and violet. We recently saw fine examples of it in Sir Trevor Lawrence's garden at Dorking, and also in Mr. Williams' nursery at Holloway.

M. Bergman.—It is proposed by a number of the friends of M. Bergman, of Ferrières, to make a pleasant manifestation on the fiftieth anniversary of his entry into the employ of the house of Rothschild at Ferrières. Many who are interested in the finer class of gardens will remember well M. Bergman's kindness and courtesy to all visitors. His friends intend to open a subscription in order to offer him a pleasant souvenir of their goodwill, and to call to mind, at the same time, the many services rendered to horticulture by this able and modest gentleman. It is proposed to offer a work of art on which will be engraved the date and object of the donation—an album containing the portraits of those who subscribe, and another containing their signatures.

Bougainvillea speciosa.—I forward a spray of this plant for your inspection. We generally read that it is difficult to flower, and this is the first season that our plant has bloomed. It is growing in an intermediate house, and is planted out in a box 3 feet long, 18 inches deep, and 10 inches wide, well drained in turfy loam, and has been there three years. It has had but little water during the winter. The young growth is kept pinched in, and it is on the short spurs of last year's growth, and not on the young wood, that it is flowering.—ROBERT SMITH, *Presdals, Hare, Herts.*

* * A remarkably fine spray of this beautiful greenhouse climber.—Ed.

Toxicophlæa Thunbergi.—This fragrant stove Evergreen, which is grown in some gardens under the name of *T. spectabilis*, is now in great beauty at the Botanical Gardens, Edgbaston, Birmingham, where Mr. W. B. Latham has a fine specimen of it fully 5 feet in height and profusely flowered. The plant was sent here from a private garden in which it did not bloom, and Mr. Latham tried the experiment of cutting it back hard, and then allowed

it to make a vigorous growth, with the result that it is now in full bloom, the shoots being densely crowded with corymbs of white, sweet-scented, Ixora-like flowers, which issue from the leaf axils. It would appear to be blooming a little earlier than usual at Edgbaston than is generally the case, but this is probably owing to the treatment it has received. In addition to its free-flowering quality, its exquisite fragrance deserves especially to be noticed. When I first saw this plant eighteen years ago in one of the stoves at Farnleigh, Dublin, it was in bloom in August, but on two and three-year-old wood, and some of the flowering branches were 2 feet to 2½ feet long. Now it would appear as if it blooms most abundantly upon the young matured wood. It is a most useful and attractive early spring flowering stove shrub.—R. D.

Hovea elliptica is the correct name for a beautiful little Australian shrub, known better in English gardens under the name of *H. Celsi*. It is a small bush with long slender shoots which some would call straggly, but these are wreathed with myriads of small flowers of the richest purple-blue imaginable. It is one of the multitude of Australian shrubs that once were the pride of many English gardens, but even now it is insufficiently known, for one may go in twenty good gardens at this season and not see it in bloom. Those who want bright and uncommon looking flowers should grow this *Hovea*. It is not a difficult plant to grow if treated rationally. It wants sandy peat to grow in, and careful attention as to watering. It is in bloom at Kew.

New Roses.—In their beautiful group of pot Roses at South Kensington on the 22nd inst., Messrs. Paul and Son, of Cheshunt, had fine examples of two of Guillot's recent novelties. It often happens that Roses flowered under glass vary much in colour from the same varieties when flowered out of doors; but in the present instance both *Gloire Lyonnaise* and *Souvenir de Gabrielle Drevet* were thoroughly in character. The pretty white flowers of the former, with their lemon-tinted base, are now becoming well known; but the latter promises to be a most valuable addition to the Tea Roses, having large deep flowers of a charming rosy tint on a creamy white ground, the high centre being surrounded by large petals whose margins are gracefully reflexed. It is unquestionably the best of the 1885 novelties, as it blooms out of doors exactly as shown by Messrs. Paul.

Mr. Penny's orphanage scheme seems to be progressing vigorously, if we may judge by the first list of subscribers which to-day appears in our advertisement columns. It contains the names of some of our best gardeners, a good guarantee that the project will succeed. Mr. A. F. Barron, Royal Horticultural Gardens, Chiswick, Mr. Wynne, and Mr. Wright have been appointed secretaries, and suggestions and subscriptions may be sent to them, or to Mr. Penny, Sandringham. An Orphan Boy says: "What he would like to see, and would be willing to subscribe to, would be a fund invested safely and managed cheaply that would afford a substantial reward or prize to as many young gardeners as possible every year who passed an examination for proficiency in their business and received a certificate from of the same from some properly constituted body." The better education of gardeners has, he says, been everybody's cry since he remembers; it is more needed now than ever, and would benefit both the parents and the children, and now is the opportunity.

Eucharis mite.—It seems to me that the injury caused to many plants by this insect is not so fully known as it should be. Having had to deal with it in its native country, I know well how difficult it is to eradicate. It would surprise some of the readers of THE GARDEN to know how long it will live and, at times, even multiply on a few dried leaves in a tin box. Its ravages are not confined wholly to the *Eucharis*, but extend to many other genera. In some of the large plant-growing establishments throughout the kingdom thousands of valuable plants die annually from the effects of this mite. It enjoys a dry, hot atmosphere and bright sunshine. Fumigation and dipping in tobacco juice may, to some extent, keep it down, but the French method of evaporating tobacco juice, some time ago advocated

in THE GARDEN, will not kill it. Its introduction to this country is of comparatively recent date, but no doubt millions come home yearly with importations of plants, Palm seeds, &c.—ROBERT CROSS, *Corston-phine, near Edinburgh.*

Lime for Cyclamens.—Having read the note on hardy Cyclamens by "Olotir," page 248, and these plants being especial favourites of mine, makes me write to suggest that where lime is not naturally present in the soil, when hardy Cyclamens are planted, a little old mortar or other spent lime should be added to it. We have, at Wisley, hardy Cyclamens in different soils and situations all growing fairly well, but not so fine as I saw long ago at Mr. James Atkins's garden at Painswick; so having one rock bed, in which a good deal of old mortar had been mixed with the soil, that we might test whether plants liked lime or not, we planted some Cyclamen Coum in this. The increased size both of the flowers and leaves shows that lime increases the vigour of the plant. I am, therefore, trying other species in the bed.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

ORCHIDS.

W. H. GOWER.

ORCHIDS AT BURFORD LODGE.

AMONGST Dendrobiums many hundreds are now in bloom here, or promise to be so ere long. The most noteworthy now in flower are *D. Ainsworthi*, its varieties, and its near relative *splendidissimum*; these are hybrids obtained in different ways between *D. nobile* and *D. heterocarpum*; their colours are those of the parents, beautifully blended, and they also retain the grateful odour of Violets which is such a distinctive character in *D. heterocarpum*. *D. Wardianum* in many forms is also now in great beauty, from the slender-stemmed Assam form to those with thick stems and knotted joints, varieties of *giganteum* largely imported by Messrs. Low, of Clapton, from Borneo; also the rare white form called *candidum*, in which the waxy sepals and petals are pure white throughout, and entirely devoid of the richly-coloured tips which occur in the normal plant. The lip is white, with a stain of pale orange-yellow at the base and a faint spot of pale brown on either side. This form still keeps extremely rare. *D. Jamesianum* is another white-flowered species, and one of the most beautiful of its class; it belongs to the *nigro-hirsute* section, of which *formosum giganteum* is a familiar example; this section is characterised by stout, erect growths and stem-like pseudo-bulbs more or less densely clothed with short, jet-black hairs. The flowers of *Jamesianum* are large and spreading, pure white, with the exception of the base of the lip, which is stained with cinnamon. These last many weeks in full beauty. In direct contrast to the purity of the last-named kind stands *D. nobile nobilium*, the beauties of which seem every year to become better developed. Of *D. nobile* itself, innumerable forms are now in bloom, some having intensely dark flowers, passing through paler shades to almost white, but *nobilium* is undoubtedly both the largest and darkest-flowered variety belonging to this type yet introduced. Its blooms measure upwards of 4 in. across; the sepals and petals are broad, thick, and fleshy in texture, and rosy purple, becoming slightly paler at the base; the lip is white with a broad marginal band in front, of deep rosy purple, whilst the large eye-like spot at the base of the lip is intense purplish crimson or maroon. *D. Hardyanum*, a curious and distinct species, has not yet been seen in the form of large specimens, but it gives good promise of becoming a general favourite; the flowers are deep rich yellow, the lip being stained on either side with a blotch of orange-yellow and fringed, as are also the petals. Those acquainted with *D. Brymerianum* will readily glean some idea of the appearance of this novelty. *D. Findlyanum* and its rose-coloured variety are both charming plants, which produce numerous large lovely flowers upon short spikes which proceed from knotted joints. In the typical plant the sepals and petals are white suffused with pink or pinkish rose; the lip, which is orange-yellow at the base, becomes paler towards the front. In the variety *roseum*, the whole flower is suffused with rosy pink.

D. crassinode is a mass of beauty, its large, waxy-white flowers tipped with magenta of various shades being strikingly effective. Species belonging to the *densiflorum* section are numerous, conspicuous amongst which being such kinds as *chrysoxum*, with pendulous, somewhat lax, bunches of golden flowers, and *Farmeri*, with its drooping trusses of pinkish white and yellow flowers. Of kinds with pendulous growths, the most noteworthy are fine examples of *D. primulinum* and *D. primulinum giganteum*, bearing long racemes of large blossoms, the sepals and petals of which are creamy white flushed with pink, and stained with pale yellow in the lip. *D. cretaceum*, a smaller kind, and one rarely grown, is nevertheless extremely beautiful; its flowers are creamy white, the lip being pale yellow in the centre, and faintly streaked with crimson; other species are *D. album*, many varieties of the violet-scented *D. heterocarpum*, and the curious Australian *D. tetragonum*, which, although not particularly showy, is extremely curious and almost a perpetual bloomer. Large specimens of the typical *D. limbratum* are also bearing numbers of pendulous trusses of rich golden flowers, the lips of which are beautifully and heavily fringed.

Of the Lady's Slippers (Cypripediums), fine examples, such as *hirsutissimum*, *Haynaldianum*, *Harrisianum*, *villosum*, and *Schlimi*, are blooming freely. *C. barbatum Warneri* is a most conspicuous and charming form, although compared with other varieties its blooms are small; its brilliant dorsal sepal is specially attractive; moreover, it appears to be constantly growing and sending up fresh flowers nearly all the year round. Here are also grand specimens of the Philippine Island *C. argus*, with beautifully marbled foliage and much spotted flowers, together with the best form of *C. Dayanum* and *Lawrenceanum*, all of which are beautiful and showy plants, even in the absence of flowers; in *C. vernixium*, *C. argus* and *C. villosum* are fairly blended; it is remarkable that the peculiar varnished-like appearance of the flowers of the latter species is invariably transmitted to its progeny.

PHALANOPSIS are well represented by the two fine old species *P. grandifolius* and *P. Wallichi*, their ample bright green plaited leaves showing off to advantage their countless numbers of bold, erect, many-flowered spikes; the more recent introduction from Madagascar, *P. tuberosus*, is also represented, and although a somewhat difficult plant to cultivate, it appears to thrive and bloom here in the freest possible manner; one plant of it is particularly notable, being much shorter jointed and closer in its growth than the others; the sepals and petals are pure white, whilst the peculiar somewhat funnel-shaped lip, instead of being yellow at the sides, dotted with brownish crimson, is profusely spotted and blotched with rich crimson-maroon. The front lobe is white, spotted with magenta-purple, the crests being deep orange-yellow.

Conspicuous amongst Angraecums is *A. Ellisii*, the Cockatoo Flower, a species which bear long racemes of pure white, long-spurred flowers, which have the additional recommendation of being fragrant. *A. Kotschyi* is somewhat similar to the last named kind, but smaller, and the spur is twisted, also the rare *A. fastuosum*, which promises to become a dangerous rival to the West African *A. caudatum*. The free-blooming *A. citratum*, with long racemes of closely set creamy white flowers, with just a tinge of sulphur-yellow in them, is also specially noticeable, as is likewise the curious and minute-flowered *A. hyaloides*.

AERIDES are represented by the rare and seldom seen *A. vandarium*, which is sometimes (but erroneously) named *A. cylindricum*. It resembles somewhat in growth *Vanda Hookeriana*, and produces pure white flowers in pairs on short spikes; these last a considerable time in perfection; the specimen in question has produced upwards of thirty flowers this season. Another plant with somewhat the habit of the Fox-brush *Aerides* bears two long racemes of pure white flowers. It is at present unnamed, and quite a novelty in the genus. *Vandas* are represented by good varieties of *V. carulescens*, the beautiful blue flowers of which contrast admirably with those with which they are associated. *Cattleyas* were over; sufficient, however, remained to show that *C. Trianae* had been very fine, whilst *C. Percivaliana*, in the shape of a large and very richly coloured variety, still lingered in flower.

ODONTOGLOSSUMS—such kinds as *triumphans*, *Pescatorei*, *Wilckeanum*, *nevadense*, *Sanderianum*, *Rossi*, and *Cervantesi*, and numerous fine forms of *crispum*—may be seen here in abundance. In the *Odontoglossum* house are two fine examples of *O. Edwardi*, bearing large branching panicles laden with flowers, which, although small, are totally different in colour from that of any other known member of the family, the sepals and petals being violet-mauve, and the lip purple with a yellow crest. This is surely a plant that will be turned to account by the hybridist. The allied genus *Oncidium* is at present represented by *O. bifolium*, a dwarf, compact-growing species from Monte Video, which may be described as a miniature form of *O. varicosum*, the Rush-leaved *O. Cebolleta*, *O. Phalenopsis*, and some highly marked forms of *O. sarcodes*. Amongst the somewhat despised family of *Epidendrum*s, *E. Wallisi* is both conspicuous and handsome. It belongs to the erect-growing section, with Reed-like stems, and bears large flowers both on terminal and lateral racemes, the whole forming a dense panicle of sweet-smelling blooms. The sepals and petals are golden yellow dotted with red; the lip is broad in front with a cuneate base, white, ornamented with numerous radiating feathery lines of bright purple. *E. radicans* is also now very finely in bloom, its corymbiform racemes being bright orange-scarlet, whilst several forms of the old and new seldom seen *E. Stamfordianum* are bright and attractive.

MANDEVALLIAS are most vigorous, and numbers of scapes just rising bid fair to produce a grand display. We noted, however, the rare *M. Crossi*, with good-sized flowers of an intense crimson-scarlet, and produced in quantity. *M. ignea aurantiaca* is a large form, with a very distinct shade of orange in its flowers. The charming *M. Shuttleworthi*, which appears to be always in flower, has here as an associate a species resembling it in shape, but not so large, called *Indibunda*; in this the sepals are yellow, the basal half of the upper one being stained with purple. *M. Schlimi* is a curious form, producing a raceme of flowers somewhat crowded; the sepals, which are light purple, are freckled all over with dark purple dots, the long tails being yellow. There are also still numerous examples of *M. tovarensis*, with their snowy flowers; whilst the section to which *M. polysticta* belongs is only just opening. *M. Fraseri* is a very handsome kind, with rosy purple flowers, which suggest the idea of its being probably a hybrid between *M. ignea* and *M. Harryana*. One of the most curious members of this family is *M. culex*, which has tiny white flowers, profusely freckled with maroon-coloured dots.

Angraecum sesquipedale.—Hundreds of this remarkable plant may be seen in Mr. Low's nursery at Clapton. The flowers are of gigantic size, ivory-white or creamy white in colour, and have a fragrance like that of our common white Lily. They are thick and fleshy in texture, the lip being furnished with a very long spur, which, to accord with its name, should measure 18 inches in length, but it seldom attains more than 12 inches or 15 inches in this country, although upon one or two occasions we have seen it sufficiently long to merit the name. This plant, although known to science for many years, was not added to our collections until Ellis, on his last return from Madagascar, brought it, and in whose collection it bloomed for the first time in 1857. Ellis sets a good example to plant collectors, for in describing its habitats he gives valuable information to the cultivator. He says:—

It does not grow in the moist and thickly wooded parts of the island, but generally on straggling trees along the edges of the forests or in parts where the trees are only sparingly spread over the country. It seems to grow most frequently on the driest parts of the trunks and branches of thinly-leaved trees, and, though occasionally, was seldom found near the ground. The largest plants grow about 12 feet or 20 feet up, and smaller ones were often seen higher amongst the smaller branches. In these situations the leaves were neither numerous nor large, and in its native state the plant most frequently presented a starved appearance and straggling habit, but it produced a profusion of bloom of a pure ivory-white. Where found growing in constant shade and moisture, the plants were better furnished with leaves, but produced fewer flowers, and these were creamy white (not ivory-white).

Under cultivation this is very handsome, even when not flowering. The leaves are arranged in a distichous manner, tightly clasping the stem at the base,

recurved at the tips and of a deep bluish-green, whilst the large white flowers produced at this season are very persistent and render it most attractive.—G.

MOTH ORCHIDS.

(PHALANOPSIS.)

THE first species of *Phalaenopsis* with which Orchid growers were made acquainted was *P. amabilis*, introduced from the island of Luzon in 1836 by the Messrs. Rollisson, of Tooting. A few years afterwards came *P. grandiflora* from Java. After these, *P. rosea* and *P. Lobbi* were sent home by Lobb, then collecting in the Philippine Islands. It was some years afterwards before *P. Schilleriana* was introduced—in the first place to Belgium by M. Linden, of Brussels, and immediately afterwards to England by Mr. Williams, of Holloway. Since then many forms have been introduced, and others are said to be on their way to this country. *P. amabilis*, like all its congeners, is destitute of pseudo-bulbs; it forms a short stem, from which

over, are bright, light green on both surfaces. The scape bears a raceme of lovely flowers. These scapes should not be removed from the plants when the flowers decay, as in the succeeding year they produce lateral shoots, which bear quantities of blooms. We have seen plants thus treated bearing from sixty to eighty flowers, each measuring about 4 inches across. The flowers of *P. grandiflora* are pure white, with the exception of the side lobes of the lip, which are yellow, as also are the recurved tendrils, which proceed from the tip of the middle lobe. The variety *aurea* is a native of Borneo, and is chiefly remarkable for having the base of the lip stained with deep orange-yellow. *P. Sanderiana* is a lovely flower introduced by Mr. Sander, of St. Albans, and named by Professor Reichenbach. It is considered by some to be a natural hybrid between *P. amabilis* and *P. Schilleriana*, but Mr. Sander says it comes from a total different locality from that of any of the other known kinds: indeed, we look upon it as a form of *amabilis*, with rose-coloured sepals and

between *P. rosea* and *P. amabilis*; the flowers are medium sized, the sepals and petals pure white, the latter much the largest, lozenge-shaped, and freckled near the base with rose-coloured dots. The middle lobe of the lip is ovate, furnished at the apex with two short recurved tendrils, rich crimson in colour, the side lobes being wedge-shaped, rosy violet dotted with crimson. *P. intermedia* Portei, introduced from the Philippine Islands, upon first flowering was supposed to be a hybrid having the same origin as the last (*i.e.*, *rosea* crossed with *amabilis*), and this conjecture has been verified by Messrs. Veitch, who have obtained the same form at Chelsea from seeds the result of a cross. The sepals and petals are white, slightly tinged near the base with rose. The middle lobe of lip is ovate, and furnished with two short tendrils at the apex, which stand forward; they are deep purplish rose colour tinged with yellow at the base, while the side lobes are rose-coloured. *P. intermedia* Brymeriana appears to be a natural hybrid between *intermedia* and *Schilleriana*; the flowers are almost identical in shape and size with those of the first-named plant, whilst the foliage is faintly marbled after the manner of that of the latter. The sepals and petals are white, tinged with soft rose, the lateral sepals sometimes faintly flushed with purple; the front lobe of the lip is violet or amethyst, stained at the base with bronzy yellow, a colour which also pervades the side lobes, which, in addition, are streaked and dotted with magenta. The apex of the lip is furnished with two short tendrils.

P. SCHILLERIANA differs materially from all the other known kinds in having its foliage beautifully marbled and banded with silvery grey upon a dark green ground, the underside being purple; on different plants these markings vary much in brilliancy. The scape branches the first season, and when the plants are strong produces numerous flowers (sometimes upwards of a hundred); these flowers vary from light mauve to rosy lilac, fading away to white on the edges; the lip is rosy lilac on the ovate front lobe, furnished with two diverging points, resembling somewhat in shape the tail of the black grouse. The side lobes are white dotted with red and bear a yellow fleshy mass at the base. The variety *vestalis* has white flowers; *delicata* is also a white-flowered form suffused with a faint tinge of flesh colour, whilst the variety *splendens* is a form with large blooms of a deep, rich rose colour. *P. Stuartiana*, introduced by and named in honour of Mr. Stuart Low, of Clapton, where we recently saw many hundreds in flower, evidently belongs to the *Schilleriana* section; its foliage, however, is not so conspicuously banded with grey as that of *Schilleriana*, and the bands become almost obliterated when the leaf is mature. The flowers are similar in shape to those of *Schilleriana*; the sepals and petals are pure white with the exception of the lower half of the lateral sepals, which have a yellow ground colour, profusely dotted and spotted with cinnamon; the side lobes of the lip are furnished with similar colours, and have an orange-coloured callus at the base; the front lobe is pale yellow, dotted and spotted with red; the apex is furnished with two fluke-like appendages. The variety *nobilis* has larger flowers, and the spots, though less numerous, are larger in size. In *punctatissima* the sepals and petals are profusely freckled with red dots. *P. leucorrhoda* is also one of the hybrids which are supposed to have originated between *Schilleriana* and *amabilis*; the foliage is similar to that of the first-named plant, but much less distinctly mottled, whilst in some forms it is wholly absent; the sepals and petals are white, the latter flushed with rose at the base, whilst the lateral sepals are dotted with purple, the lip being streaked with purple with yellow on the disc. *P. casta* is another form supposed to have had the same parentage as the last; the leaves are slightly marbled when young, but the markings usually disappear by the time they reach full size; the flowers in a great measure resemble those of *amabilis*, being white faintly flushed with rosy purple; the lateral sepals are spotted with the same colour.

Phalaenopsis amabilis. Engraved for THE GARDEN from a photograph.

issue numerous vermicular roots, by which it adheres firmly to the stems of the forest trees or the rocks upon which it is found. The leaves are arranged in a distichous manner; they are somewhat oblong obtuse in shape, thick and fleshy in texture: on the upper side they are deep, shining green, and dull purple or slate coloured beneath. The scape is long and drooping, becomes branched when old, and bears many large, moth-like flowers arranged in a two-ranked manner. The individual flowers are round and full, some 3 inches across, pure white, with the exception of the lip, which has the base of the side lobes streaked and flushed with rosy red, and slightly tinged with yellow. In the variety *Dayana*, which is a highly-coloured form, the lower sepals are profusely dotted with carmine, the base of the middle lobe of the lip being suffused with soft crimson, whilst the side lobes are deep yellow on their front edges, and streaked with crimson near the base. *P. grandiflora* is at once distinguishable from *amabilis* by its longer and more pointed leaves, which, more-

petals; the slender tendrils at the end of the lip are somewhat short. *P. rosea* resembles *grandiflora* in growth, but it is altogether a smaller plant; its scape is erect, and bears a panicle furnished with many flowers. The sepals and petals are white, suffused with rose, the front lobe of the lip being rosy purple and quite destitute of cirrhi, whilst the colour in the side lobes is much paler. This species varies greatly in colour, some being very bright, especially the variety *aurantiaca*, in which the flowers are not only larger than those of the type, but the base and side lobes of the lip are rich orange-yellow. *P. Veitchiana* is supposed to have had for its parents *rosea* and *Schilleriana*. The scape resembles that of the first-named kind, but the flowers are more in the way of those of *Schilleriana*, but smaller. These are soft purple in colour, passing into white at the margin. The lip is purple, edged with lilac; there are several forms which differ somewhat in colour. *P. intermedia*, the *P. Lobbi* of Messrs. Veitch, is supposed to be a natural hybrid

P. Lowi is altogether a distinct species; it grows naturally upon exposed rocks near Moulmein at about 250 feet elevation. It loses its leaves during winter, and has a provoking habit of never making any more, unless great care is exercised in its management. The scape, which is branched, bears numerous, somewhat small flowers, which, however, are round and full; the sepals and petals are white, faintly tinged with rose, the front lobe of the lip being purplish violet. It has not hitherto yielded any hybrid forms or special variations. *P. Luddemanniana* resembles *rosea* somewhat in habit, but the flowers are very distinct; the flowers, which are produced freely, are creamy white, flushed with pale violet, and transversely banded with streaks of amethyst; the lip is deep violet in front, faintly blotched on the side lobes with yellow. *Ochracea* differs in having the sepals and petals dull yellow, flushed with rose, the transverse bands being reddish brown. *P. violacea* comes from the neighbourhood of Singapore, and is a sturdy plant, producing broad, deep green, deflexed leaves, strongly ribbed. The scape bears a few flowers only, which are medium-sized, the dorsal sepal and petal being creamy white; the lateral sepals are somewhat falcate in shape, deep purple, bordered with creamy white; the column and front lobe of the lip are deep purplish magenta, the small side lobes being yellow, as is also the callus. The variety *Bowringiana* differs from the others in having a light yellow ground; the sepals and petals are freckled with rosy purple, the inner halves of the lateral sepals being of the same colour; whilst in *Baron Schroederi* variety (*Schroederi*) the sepals and petals are faintly banded with purplish streaks.

P. SUMATRANA, sometimes called *zebrina*, is a rare and handsome form, from the island of Sumatra, with somewhat the habit of *Luddemanniana*. The sepals and petals are rather narrow, yellowish white, broadly barred and blotched with reddish brown; the lip is white, spotted with orange, and sparingly streaked with violet. *P. speciosa* is a small-growing plant, discovered in the Andaman Islands. It has flowers of a deep crimson-purple, indistinctly barred with white lines. *P. Mariei*, from Bornco, is quite a gem. It has somewhat the habit of *sumatrana*; the sepals and petals are white, transversely barred with deep red; the lip is magenta-rose, the front lobe being narrowly bordered with white. *P. Reichenbachiana* also belongs to this section. It has cream-coloured sepals and petals, marbled with purplish red or crimson blotches; the lip is rosy mauve, stained with orange on the side lobes. It is one of Mr. Sander's recent introductions from the Indian Archipelago. Other kinds of less beauty are *P. tetraspis*, *Cornu-cervi*, *Parishi*, *antenniferi*, *amethystina*, *Manni*, *Corningiana*, *Valentini*, and *fasciata*.

Where a large collection of *Phalenopsis* is maintained, it will be found most convenient to devote a house specially to them, but in the case of a few specimens only they should be placed together in one part of the East Indian house. These plants enjoy abundance of moisture at all seasons, especially when making their growth. At whatever time of the year young leaves appear, the plants should be encouraged to grow, as checking them by withholding water at such times is sure to prove disastrous. *Phalenopsis* require considerable heat, yet they will not long survive if subjected to too high a temperature. During winter, by which we mean from about November to March, 65° to 68° in the daytime, and 60° to 65° at night, will be sufficiently high. During the remaining portion of the season 70° by night, rising to 80° by day or more with sun heat, will suit them admirably. The temperatures should be maintained together with a free circulation of air, and the atmosphere should be sufficiently charged with moisture to prevent aridity. They may be grown in pots, or baskets, or upon blocks of wood, according to fancy, but avoid burying their roots in the potting material; indeed, the less *Sphagnum* used about their roots the better. The sun should not be allowed to shine full upon

them during mid-day, nor, indeed, at any time when their leaves are wet, and a thin shading material must be provided for their protection at such times; it should be so fixed as to be about 1 foot above the roof, by which means a current of air passes over the glass, and thus maintains a genial atmosphere in the house. *Phalenopsis* are not easily increased, except from seed, or by means of occasional offshoots which sometimes are found upon their flower-spikes or roots; when this occurs they should be encouraged to establish themselves upon a small block before they are detached from the parent plant. *P. Luddemanniana* is perhaps the freest of all the known kinds to increase in the above-mentioned manner. *Portei* and one or two other kinds produce young plants upon their flower-spikes, and several instances of *Stuartiana* forming young plants upon its roots are also recorded, but the chief source of increase in numbers must arise from importations, or from seeds raised at home, this latter system being both a long and tedious one. In the early days of our experience with *Phalenopsis*, the treatment accorded them was most uncongenial, and although they appeared to grow vigorously for a time, they eventually sickened and died, but, nevertheless, their cultivation is not difficult. W. H. G.

ORCHIDS IN BLOOM AT KENWOOD, ALBANY, N.Y.

THE Orchid houses here are now well furnished with bloom, there being not less than 130 varieties open at present, these including some of the very choicest kinds, a few of them being unique specimens. As an English nurseryman remarked the other day, pointing to three *Phalenopsis*, "These varieties we have to cross the ocean to see." I think we are fully a month earlier in this country, as all our *Lælia anceps* and its varieties (of which we had about 400 spikes) have been out of flower more than a month; the *Cattleyas* are past their best, and the *Odontoglossums*, which usually bloom in the spring in England, are now beautiful. Among the hundreds of *Cattleya Trianae* in flower may be seen an immense number of varieties, but these may all be grouped under half-a-dozen named kinds; among the most distinct are *Barkhouseana*, conspicuous for its crimson-tipped petals—this peculiarity in one variety is extended to the sepals; *Osmani* has large rosy sepals and petals, with a brilliant coloured lip; *nivea* and *alba* are types of the delicate section; *Bonnyana*, *Victorie*, *excellens*, *Russelliana* all good, but one name is sufficient; *Rougieri* and *quadricolor* represent the dark varieties. The *Phalenopsis* are particularly rich in variety at this season; the albino form of *Schilleriana*, called *advena*, is very attractive; *leucorrhoda* and *Veitchi* have also their albinos in *alba* and *brachyodon*; the marbled and dark rose forms of *Sanderiana* are improvements on the type. Two grand forms of *speciosa* are *Christyana* and *Imperatrix*. The first cultivated seedling of *Phalenopsis Portei* is doing well and flowers continually; *Brymeriana* is a brighter variety with green leaves; the new *Reichenbachiana* is in flower, and proves to be a distinct variety; *Luddemanniana*, *Stuartiana*, and varieties are in profusion. By the way, young plants forming on the roots of this species are now of common occurrence, and these are better taken off as soon as the first leaf is formed, and potted, when they will soon make nice plants. There is a wealth of bloom in the *Dendrobium* house, more particularly in the *Wardianum* section; both the white and yellow forms are conspicuous; the latter, *ochroleucum*, is a particularly showy variety, and should be in every collection, as also is the nobiliss form of *Dendrobium nobile*. This is probably the dullest season of the year for *Cypripediums*. The collection includes every known variety of this fascinating genus. The hybrids of *Sedeni* are plentiful and in flower nearly all the season; among them in bloom are *Sedeni variety candidulum*; *cardinale*, so much resembling our *Moccasin* flower of the swamps; *calurum*, a somewhat coarse variety compared to *albo-purpureum*,

and *Schroederæ*; the old *Phaius grandifolius* and *Wallichi* are in fine flower, with over seventy-five spikes; *Phaius irroratus* is a lovely Orchid, but not so showy as *Phaius irroratus purpureus*, which more nearly resembles *Phaius grandifolius* in its growth. The cream of the *Odontoglossums* at present are the two unique varieties *Shuttleworthi* and *Shuttleworthæ*, the last is probably the prettiest of all the *Odontoglossums*, and is evidently a natural hybrid from *triumphans* and *Pescatorei*. The *Hystrix* type shows great variation, and among the heavily blotched varieties are *lycoglossum*, *Wilckeanum*, *guttatum*, &c. *Pescatorei* is a much later flowering species, but promises well for flower. *Cooksoni* is an extremely free spotted form of *crispum*. *Mulus*, which is now getting very plentiful, is represented by several specimens. *Gloriosum* is in innumerable variety, including such distinct forms as *Andersonianum*, *baphicanthum*, *Ruckerianum*, *hebraicum*, *deltoglossum*, *odoratum*, *Sanderianum*, and *constrictum*. F. GOLDING.

Masdevallia Ehippium.—This interesting species is not often seen in cultivation. In the *Botanical Magazine*, where it is figured under this name, it is stated that it was first discovered at Loxa by the late Dr. Krause. Mr. Gustavus Wallis, who discovered it in New Granada, says he found it growing on the frosty heights of the Sonson district. It succeeds, it is said, quite as well in a loose compost as on the bark of trees, and even in a common heavy soil; in its native home it grows in highly elevated regions, as cold as any in which *Masdevallias* can exist. This species has been cultivated under the names of *M. Colibri* and *M. Trochilus*. It is useful to know that it can be cultivated in the coolest house. *M. Chimera*, on the other hand, is a native of deep valleys in the same country. This species and its allied forms succeed best in a warm temperature. We grow them in the Mexican house during the six coldest months in the year.—J. D.

Lælia harpophylla.—This is at once a most distinct and peculiar plant, the colours of its flowers being both rare and showy. Its habit suggests the idea that it may be a natural hybrid. If, however, such is the case, it has been produced in quantity and not in single plants only, which appears to be the case with *Odontoglossum mulus*. It belongs to the *L. cinnabarina* section, but differs from that species in having quite slender, stem-like pseudo-bulbs, which vary in height from 6 inches to 12 inches, and bear single strap shaped, pointed, coriaceous dark green leaves. The scape springs from the top of the pseudo-bulb at the base of the leaf, and bears six or seven rich, bright orange-vermillion flowers, the sepals and petals of which are lanceolate and acute, and nearly equal in size. The middle lobe of the lip is long and narrow, recurved at the point and white, both edges being beautifully frilled. A fine form of this brilliantly-coloured species, measuring upwards of 3 in. across, comes to us from Mr. Laing, of Forest Hill, in whose nursery this plant is just now flowering profusely.—G.

Orchids at Oakwood.—A remarkably well-grown and select collection of Orchids may be seen at Oakwood, Troy, N.Y. Mr. Smith, the owner, is a great lover of these, and attends personally to their wants. He strongly advocates outdoor treatment in summer for a great many species, including all the so-called cool Orchids. After many years of experience, he has been enabled to weed out all that are not amenable to this treatment, reserving only *Phalenopsis*, a few *Cattleyas* and *Dendrobies*. He has constructed a large platform (the supports of which are placed in pans of lime as a preventive against slugs) under some shady trees, which have been thinned so as to allow abundance of light. The plants (of which there are several hundreds) are brought here early in June, and remain until the latter part of September. There is no protection afforded them from extremes of weather, but every dry day they are holed overhead twice. That they enjoy this treatment is evident by their healthy appearance for more robust and vigorous plants I have never seen. Among those particularly noteworthy are *Cologyna cristata* and *C. ocellata*, of which there is

an immense number. A fine specimen of *C. Massangeana* is growing very freely, and is constantly in flower. *Cymbidium eburneum*, Mastersi, and Lowi are in quantity, and represent the most robust plants I have yet seen, not an imperfect leaf being on them, and they flower as freely as Geraniums. One fine specimen of *C. Lowi* at the time of my visit had 16 spikes and 320 flowers. A large plant of *Odontoglossum citrosimum* was particularly striking. I saw this plant last year with seventeen large branching spikes. All the *Odontoglossums* are in fine health and developing large sturdy spikes. A batch of *Cypripedium insigne* was flowering for the second time since last winter. I noted a fine variety of *Laelia anceps Hilli* with flowers as well formed as Dawsoni, and larger than usual. Among the varieties of *C. Trianae* were two fine forms of *C. Trianae alba*. Altogether the collection is very noteworthy, particularly to Orchid growers, as demonstrating the value of outdoor treatment during our hot summer months, especially to those whose houses are not fitted for summer work, or have not the time to give them the attention they need.—F. GOLDRING.

Coelogyne cristata.—Mr. Douglas's remarks respecting the cultivation of this *Coelogyne* have prompted me to say a few words respecting it. Previous to coming here I was second gardener at Mr. Peacock's, Sudbury House, Hammersmith. The *Coelogyne*s there were removed to a cool house in which *Masdevallias* were grown, *etc.*, after some remarks had appeared in one of the papers on cool house culture, but they only made small bulbs and flowered but poorly. There were upwards of fifty plants, and I can safely say that I have this season had more flowers on four in 22-inch pans than we had annually there on the number just stated. Our plants here, after growth had commenced last season, were potted and placed in the warmest house, and there they remained until they had finished their growth. Last season many of the spikes had only five flowers on them, but this season many have carried six and seven, and in one pan there have been thirty spikes.—F. A. PAGE, *Mount View, Sheffield.*

ROSE GARDEN.

T. W. GIRDLESTONE.

ROSE-PRUNING.

WITH the advent of March, and lambs, and Daffodils, and east winds, and other genial indications of that period which pastoral poets, with the license too readily granted them by an indulgent public, have been apt to describe as "balmy spring" (?), the rosarian mind adverts to Rose-pruning. At the same time it should not be considered necessary because that which is generally considered the pruning month has come that pruning should be forthwith proceeded with, regardless of any other considerations, and as long as frosty nights continue, especially while followed by bright sunny days, the postponement of pruning until there is a prospect of more genial weather will probably involve no real loss of time. Nothing is more aggravating than when plants which have been pruned, say in the middle of March, have their 2 inches or 3 inches of young growth cut off by a spring frost late in April, or even, as in 1886, on the 1st of May, and plants which meet with such a fate are really in a worse position, and will probably be later in flowering than if they had not been pruned at all until the middle of April. In a large collection, of course, pruning will be done at various times, but in small gardens where every plant is of importance, it is better that pruning should be done late rather than too early. The objection generally urged against late pruning is that the plants bleed so much more than when pruned before any material growth has been made at the ends of the shoots, but it has not yet been conclusively demonstrated that this bleeding is particularly deleterious to the Rose trees. The first impression would naturally be that so large a loss of sap must be injurious, but when it is considered how greatly the area to be supplied has been reduced by the removal of branches in pruning, it will be seen that it may not be impossible

that the supply for what is left of the plant is amply sufficient in spite of the apparent waste.

A few years ago an attempt was made to obtain more or less exact evidence on this point, namely, whether or not the bleeding consequent upon pruning after growth had actively commenced was injurious to Rose trees. The season was a mild and early one, and by the third week in March most of the Hybrid Perpetuals had the ends of their shoots covered with young leaves; a certain number of rows was selected, each containing from twenty to thirty strong established dwarf plants of one variety. A stake was inserted in the middle of each row, and all the plants were then pruned pretty hard, those to the north of the stake being allowed to bleed unchecked, while those to the south of it were prevented from so doing by the immediate application of painter's knotting as a styptic. Here, then, were considerable numbers of plants of the same age and in the same situation all similarly pruned at the same time by the same hand, and whereof half the plants of each variety was prevented, and the other half not prevented from bleeding. The latter certainly did bleed copiously, in many cases palpably moistening the soil at the base of the plant, but for the former the painter's knotting proved a very effectual styptic. The plants were carefully watched throughout the ensuing season, but neither in the starting of the eyes, nor in the quantity or quality of the flowers, nor yet in the subsequent growth of the plants, was any appreciable difference discernible between those that had been stypticed and those that had not; beyond that, in a few cases, the styptic appeared to have killed back the shoot a little way beyond the eye to which it had been pruned. It was concluded therefore that it was not worth while for the prevention of evil results which were so little observable to expend the considerable labour involved in the tedious operation of stopping every shoot as pruned, nor to risk the real danger of having the plants badly injured by spring frosts from being pruned before any growth commenced for the avoidance of imaginary injury from bleeding, and consequently no attempt has since been made to check the copious bleeding, in spite of which satisfactory results have been obtained in regard to both plants and flowers.

Pruning is to a great extent a matter of convenience. There is no doubt that fine flowers may be grown from any of the numerous eyes of a long shoot, say, of a Hybrid Perpetual, provided the young growth can be preserved from spring frosts; but the topmost eyes being the most precocious, are consequently most exposed to danger from this source, and as it would be very awkward to have to manage a number of plants with a bunch of Roses at the end of each long shoot (for it is not as if the buds broke evenly along the whole length of the stem—there generally start but four or five eyes at most), it is found more convenient to cut back these long shoots to a greater or less extent, in order to compel the breaking of those eyes that are best situated for the subsequent formation of the plant and to delay their growth until the chief danger from late frosts is over. In addition, the young flower-bearing growths are thus produced upon shoots sufficiently shortened and stout enough not to be liable to be much blown about by the wind, an important consideration where many Roses are grown together, and where, as is often the case, strong south-westerly winds are frequent during the Rose season.

Among the most difficult Roses to prune are some of the older summer Roses of the Charles Lawson type, which are very precocious, and consequently liable to subsequent damage by late frosts; while, if to avoid this they are pruned hard, there results an immense growth and little or no flower. There are two courses of treatment open in these cases; one, to plant such varieties in sheltered situations where they may be thoroughly protected; the other, to plant them in thoroughly exposed positions where their first growth may be rather retarded than unduly encouraged.

With the Hybrid Perpetuals that are at all worthy of the name, and with the Tea-scented varieties there is no such difficulty, because however hard they may be pruned, they are sure to bloom; the weaker-growing sorts settle the question for themselves as to how far they are to be cut down; and of the stronger varieties generally from two-thirds to three-quarters of the length of the vigorous shoots may advantageously be removed. Of all Roses, the Teas are the easiest to prune; if they have not been damaged by the winter, but little pruning is required beyond the removal of weak and twiggy growth, and where they have stood in the open through a severe winter, the frost will have reduced the work of the pruning knife to the excision of the dead shoots just below the lowest point of injury. Many growers have had great success with Teas, cutting the plants right down to the ground whether the shoots have been frost-killed or not, and though this treatment sounds at variance with the above statement that where uninjured by frost the Teas need not be much pruned, the hard pruning may be justified by considerations of situation and convenience. The fact is, that Teas will flower freely, however pruned; and consequently, those who grow them in the open and require unblemished flowers, prune hard, whereby strong shoots spring from the base of the plant capable of carrying more or less erect the flowers, which otherwise from their somewhat pendulous habit on a branching plant, might hang down against the foliage and chafe, or even become splashed with mud from the soil during heavy rain. Where, however, Teas are grown as climbers, the main object is the furnishing of the wall or fence against which they are planted, and in such a position the tendency of the blooms to be pendulous is an additional attraction; consequently, as almost every shoot will flower if allowed to remain, it is only needful to remove the twiggy branches which might interfere with the proper development of the best-ripened shoots. It may appear from this that the Teas may be pruned almost anyhow, and this is really the fact; so that anyone who is likely to be puzzled about how to prune Roses, had better devote himself assiduously to the culture of the Tea-scented varieties.

Persian Yellow and Harrison's Yellow.—

In reference to the remarks of "Hortus" on the Austrian Briers, Harrison's and Persian Yellow, I have been measuring a number of shoots of both varieties, and I find that the average height of all my plants of the former is a good 2 feet in excess of that of the latter, some of the shoots of Harrison's Yellow being over 8 feet long. I have frequently observed this difference among both maiden and cut-back plants, and, judging from its constant maintenance among plants obtained from time to time from various sources, it would seem to be pretty general. At the same time the plants of the Persian have been generally better furnished with flowers than those of the American variety, and it was for this reason, as well as on account of its more bushy habit of growth, that the Persian Yellow was recommended for the special purpose in view, and not with any idea of disparaging the attractiveness of the individual flowers of Harrison's Yellow.—T. W. G.

Hybrid Teas.—I was in hopes that the writer of the interesting article on Hybrid Teas (p. 225) would have given us the benefit of his experience as to the growing properties of this section of Roses. With me with but few exceptions they refuse to grow. I commenced with a dozen of what are called pedigree Roses when they were first distributed, but at the end of two years they were all dead except two. These were Beauty of Stapleford and the Hon. George Bancroft. Since then I have added others, amongst which Lady Mary Fitzwilliam is the only one that makes satisfactory growth. It would be useful to many if we could get information as to their behaviour in different soils and situations.—J. C. C.

Bottoming lakes.—Will some reader of THE GARDEN kindly furnish me with instructions as to the best way of forming a bottom for an artificial piece of water? The soil is

sunny, and it is therefore rather a difficult matter. Is there any better or less expensive way than making a concrete bottom, say 6 inches thick, with stones and cement?—W. H. T.

FLOWER GARDEN.

PRUNING HARDY CLIMBERS.

WHEN hardy climbers are neglected they soon become unsightly, this being especially the case with those planted against the walls of dwelling houses and other somewhat similar positions. Not only is it necessary to give good attention to climbers growing in such conspicuous sites, neatness being usually in keeping with the surroundings, but, unless periodical pruning and training are resorted to, the chances are that the climbers will be extremely disappointing as regards their habit of flowering. When all are allowed to grow at random, or merely receive a touch over with the shears, and only re-nailed or otherwise secured whenever they break away from the walls or pillars, thickets of rubbishy growth soon result, which sooner or later have of necessity to be cut clean away. Mixtures of certain climbers if judiciously carried out may be effective enough for a time, but, as a rule, the more vigorous soon overgrow their less robust neighbours, and in very many instances, when the kinds are somewhat evenly matched as regards vigour, what was at first a pleasing combination soon degenerates into hopeless confusion. I hold that it is the wisest course to keep all separated, and in most cases I find a free use of the knife at the present time to be most beneficial. As all do not require similar treatment, I propose to take a few of the best-known in detail.

CLEMATISES.—These, being particularly liable to run wild, must be attended to, even if planted in the wild garden. We usually divide them into sections, viz., early and late flowering. The former, which includes *C. cerulea*, *azorea grandiflora*, *Lady Londesborough*, *Miss Bateman*, *Albert Victor*, and *montana*, produces bloom principally or solely from the young ripened growths, and this should be freely thinned out and all dead wood cut away. This section is best adapted for training up pillars or stakes, as well as for rambling over common shrubs. It is the later flowering sorts we prefer for training against walls, in masses over windows, on the fronts of balconies, and over prominent archways. They are also admirably adapted for massing on lawns, where they may be roughly trained up stakes or over fanciful trellises, should these be preferred. It is this section that suffers soonest from neglect, as where unpruned the principal part of the flowering growth soon collects in a mass on the portion of the old wood farthest from the roots. It must be understood that the flowers are produced on the current year's growth, and in order to have this as strong and near the ground as possible, all the last season's wood should now be cut back to near where it last started. Strong, thinly trained growths, which require support as they advance, develop the finest flowers, and give a longer succession of bloom than do neglected plants. I should add that this later flowering section includes the popular *C. Jackmanni*, as well as *lanuginosa*, *Lady C. Nevill*, *Mrs. G. Jackman*, *Gipsy Queen*, *velutina purpurea*, *Tunbridgenis*, *Lady Bovill*, *rubella*, *Robert Hanbury*, and *Star of India*. All Clematises are generally supplied from the nurseries in pots, and now is a good time to plant in good loamy soil.

ROSES.—Although very generally planted, climbing Roses are not often seen in good condition, especially when they have to struggle against other climbers. Pruning is frequently neglected, and this, coupled with starvation treatment at the roots, soon renders them comparatively useless. The first to fail, or to become unsightly, are the Hybrid Perpetuals, and I am of opinion that these are unsuitable for wall culture. Teas and Noisettes are much the best, these being of lighter and freer branching growth, as well as the most continuous flowering. *Gloire de Dijon* and *Madame Berard*, which much resembles it,

Climbing Devoniensis, *Safrano*, *Adam*, *Souvenir d'un Ami*, *Catherine Mormet*, *alba rosea*, *Niphotos*, *Celine Forestier*, *Triomphe de Rennes* (extra strong), *Brennus*, and *Maréchal Niel* are all good wall Roses, and to these may be added the white and yellow Banksians and *Cheshunt Hybrid*. The latter is classed as a Hybrid Perpetual, but, as its name implies, it is an hybrid, and with us succeeds admirably against a terrace wall. As the *Maréchal Niel* flowers at every joint on well-ripened strong shoots, these should as much as possible be laid in to their full length, and if cut back directly after flowering plenty of similarly profitable growths may be secured for next season. Freely cutting away much of the weakly growth also induces the formation of the desirable stronger shoots. The Banksians flower principally on the smaller shoots or spray, and these must, therefore, be reserved, and the coarser or long straggling growths be either laid in to their full length where space remains, or else be cut away. Well ripened growths about the size of the stem of a clay pipe will frequently produce a truss of bloom at every joint, and all such should therefore be nailed or tied in, unless the situation admits of their being allowed to hang down naturally. The yellow variety with us proves to be the hardiest and freest to flower, but the white Banksian is the choicest, being sweet scented. It is also advisable to lay in well ripened lengths of *Gloire de Dijon*, but the weakly growths should be freely shortened. All the other sorts named are improved by judicious thinning out and shortening back, especially if it is thought desirable to have plenty of bloom where it can easily be reached. Roses in the open frequently receive liberal supplies of solid manure, but these growing at the foot of sunny walls stand in much greater need, and very rarely get it. An exhausted soil and little or no moisture will not long keep Roses or any other climber in good health, and ought not to be depended upon by those who wish to succeed. Solid manure being considered unsightly in such positions should be placed on the previously bared roots and then be covered with the old surface soil. In some instances a mixture of loam and rotten manure would be sufficient. Either dressing, being further supplemented with liberal soakings of water, will serve to keep the Roses in good health, and the stronger Teas are grown the finer and more plentiful will be the blooms. These also may be planted during this or the following month.

JASMINE NUDIFLORUM.—This is a general favourite, and is particularly gay at this season. Directly after flowering it may be freely shortened back. All spray and medium-sized shoots thus treated will flower at every joint the following winter or spring. Where space has yet to be filled, the leading branches may be laid in thickly to their full length. This plant is of free growth and soon neatly clothes a wall, pillar, or rockwork, against which it may be planted. The common white *Jessamine*, a very sweet-scented and charming summer flowering variety, we cut back to the main branches about this time, and the walls are soon re-clothed with abundance of flowering spray. It grows strongly when first planted, and after the walls are thinly covered with main branches, occasional re-nailing and close winter or spring pruning is all that is needed. The *Loniceras* or *Honeysuckles* we treat in much the same manner, and these always flower abundantly. The prettily variegated *Lonicera aurea reticulata*, if neglected for a time, soon loses much of its beauty. It requires to be freely cut back, and the young growths following will be much more ornamental than thickets of old wood. If cut down to the ground, it will break away strongly again and be much improved by the process.

MAGNOLIAS.—Neither the evergreen nor deciduous varieties need much pruning. All straggling shoots, if not required to furnish wall space, may be cut away, and the leading shoots be laid in till such time as the limit is reached. Winds are very destructive to the evergreen *Magnolia grandiflora*, and extra strong fastenings are required for

it; the bloom being formed at the tips of the short lateral branches, these must not be cut back in any way. All the varieties grow strongly, and are much more hardy than at one time thought to be. Our trees, rooting in a clayey loam, are very vigorous and free growing, but in order to give them a good start, it is advisable to add plenty of peat, or, failing this, leaf soil to the compost. These *Magnolias* are supplied in pots, and may be planted during the spring months.

WISTARIA SINENSIS.—According to my experience, this grand climber is not much in favour just now, very few young plants being observable. The finest specimens I have seen are in Kent, and the *Wistaria* would appear to be most popular in that county. One plant is capable of covering the front of a house of almost any size, and that, too, in a very few years. A peaty soil suits it, and may be necessary at the outset, but the roots soon spread far and wide into almost any kind of soil, including a heavy clayey loam. It may be trained somewhat similar to a Grape Vine, the main branches being laid in in a horizontal direction, and about 12 inches apart. The flower racemes will be already showing, principally on the short spurs, and all that is necessary is to cut hard back all straggling lateral growths and make good all fastenings requiring it. *Bignonia capreolata*, another extra strong grower, may be pruned similarly to the *Wistaria*.

CHIMONANTHUS FRAGRANS.—There are few plants so sweetly scented as this, and but for this fragrance it would be but little grown, the flower being small and dull in colour. It requires to be planted against a sunny wall and given plenty of head room, otherwise the result will be an abundance of rank growth and but little bloom. All the spray on our plant is well covered with bloom at the present time, and there is some bloom at the base of the stronger shoots. After the flowering period is passed, all strong shoots not required for furnishing the wall ought to be cut back freely, and during the summer any extra strong shoots are cut out, the aim being to secure as much well ripened spray as possible. A rather poor soil ought to be given this rank-growing deciduous shrub, or it will be a long time before it flowers freely.

PYRUS JAPONICA.—Both the red and white varieties of this well-known early spring-flowering plant are very attractive, and they are admirably adapted for covering house fronts and rockwork. The bloom is formed principally on short spurs, and all straggling growths should therefore be freely shortened back. Long ugly branches are most abundant on neglected plants, and their removal soon improves them in every way. *Crataegus Pyracantha* unpruned soon becomes equally unsightly; whereas if freely spurred back and young shoots laid in where possible, abundance of white trusses of bloom are produced, these in time being followed by attractive bunches of coral-red berries. Any that have been long neglected may with advantage be cut down to the ground, and it will then soon become as attractive as it most probably was before it had assumed its bushy habit.

VARIOUS.—Ivies ought never to be allowed to form much lateral growth. Better far to severely trim off both laterals and most of the old leaves; this may give the walls a rather unsightly appearance for a short time, but they will soon be re-clothed with fine healthy foliage, and thus be effective without forming a harbour for birds and vermin. Besides, unless Ivies are thus treated they are liable to break away from the walls wholesale, thus frequently necessitating a fresh start from the base. *Virginian Creepers* should also have all straggling growths cut back, and beyond this they are quite capable of taking care of themselves. Young plants of *Veitch's* variety are singularly beautiful, especially in the autumn, and strong pot plants put out at the present time, in fairly good soil, will soon cover a large area of wall-space, no training whatever being required. It is only in the more favourable southern counties where the common *Passion Flower* survives a severe

winter. This should have all loose growth cut hard back to the main branches, the bloom being produced on the young growths following this pruning. Forsythia viridissima is somewhat similar to Jasminum nudiflorum, but is of stiffer or more erect growth, and is later in flowering. Whatever pruning is necessary in order to preserve neatness should be done immediately after the flowering period. With us it grows strongly in a heavy loam, but was given plenty of leaf-soil at the commencement. Where shrubby Hibiscuses are grown against a wall, these should have all lateral growths cut back to near the main branches. Escallonia macrantha should also be kept within bounds, but the young shoots must not be generally shortened. Ceanothus azureus, a strong-growing plant suitable for clothing walls, we prune in severely, abundance of bloom being formed on the strong-branching shoots thus produced.

W. I. M.

TUBEROUS BEGONIAS FOR BEDDING.

THOSE who have a stock of these Begonias intended for the decoration of the flower garden during the coming summer and early autumn months should now set about their preparation for that purpose. Most people keep the tubers during the winter in boxes in sand. When removed therefrom they should be started in shallow boxes sufficiently deep to allow a small layer of soil to be placed over the bottom and another layer over the tubers. If the latter are one-year-old seedlings, boxes about 3 inches deep will answer well for them, but if the plants are older they will require deeper boxes. Boxes are preferable to pots, as they allow more space for the roots, which when they reach the sides of the pots turn round and become matted, a condition in which they do not take freely to the new soil when placed in the beds. The soil used should consist, say, of two parts loam, one part rotted leaves, a sprinkling of finely ground bones, and a dash of silver or coarse river sand. Place the tubers about 2 inches apart and cover them lightly with the soil. If the latter is moist when used no water will be needed for several days; water indeed would have under such circumstances a tendency to rot the tubers. Ainery or Peach house just started is a good place in which to start them into growth, but, failing these, an ordinary greenhouse answers fairly well. After a few days the soil may be gently sprinkled to prevent it from becoming dust-dry. As soon as the roots run into the soil and growths begin to push from the crowns of the tubers, remove the boxes to cooler quarters and give abundance of air to prevent the plants from being drawn up weakly. Get them into cold frames as soon as the weather will permit, and keep them covered at nights to prevent frost from reaching them, as it would quickly destroy the growth when young and succulent. When it is seen that the roots are becoming matted, transfer the plants to other boxes in which they will have more space both for root and branch, using the same kind of soil as before, but with the addition of a little more bone-dust. When re-established in the new soil water freely. Give air, too, freely, drawing off the lights whenever the weather is favourable. Plants prepared in this manner are sure to succeed provided the after-treatment is right. Very different are plants grown into a large size in heat and hardened off all at once. These when planted out decline and die. Such a manner of preparing them for outdoor work as that last named is still very common, but Begonias never thrive under such treatment.

A. B.

Seedling Polyantheses.—I have recently seen special proof of the value of sowing Polyanthus seed as soon as ripe, so as to have strong plants to go out early in the spring in preference to planting in the autumn. A quantity of seedlings raised last summer were not, because of the dryness of the soil, necessarily planted out until the autumn. Naturally, no great amount of growth could be made, and the roots

did not strike deeply. As a result, very many of the smaller plants were found to have been much lifted and required replanting. The soil also had become hard. In contrast to the above, a large quantity of seedlings, raised from last year's seed sown in July, were dibbled into frames early in the winter, and so housed. These have since been dibbled out into clean, light, well-prepared soil, and are already rooting well. These plants will suffer in no way and will strike root deeply, because spring is the proper rooting season for Polyantheses and Primroses. Plants sown in the same way a year since are now wonderfully robust, and the Primroses are already blooming profusely; whilst the Polyantheses promise a grand show of bloom later on. The plants so treated receive no check, and within twenty months of the time of sowing are very strong and carrying remarkably fine heads of bloom. Still more, I find that such plants will endure longer than if summer-planted, and thus compelled to endure the checks incidental to drought, followed perhaps by a severe winter, ere they have become fully established.—A. D.

EDRAIANTHUS DALMATICUS.

AMONG true alpine plants this must take rank in the first class. Its clustered flowers are of a strong purple colour, and the narrow leaves beset with tiny bristles are of a rich deep green. The stems are prostrate, radiating from the centre, giving the plant a close, neat habit. It

An Alpine flower (Edraianthus dalmaticus). Engraved for THE GARDEN from a photograph.

is best grown from seed sown on the spot, as it transplants badly, but the seed sometimes takes more than a year to germinate; but when well established in a congenial place it will sow itself.

Lobelia cardinalis.—Now is a good time to increase the stock of this plant, the value of which in the flower garden early in autumn, where a mass of rich colour is required, can scarcely be exaggerated. Seedlings of the Victoria type are easily raised and grow quickly into good sized plants, but for evenness of growth and colour they are not to be depended upon. If recourse has to be had to raising seedlings in order to secure a stock of plants to start with, the best habited and deepest coloured should be selected after the first year's bloom is over. If wintered in cold frames in boxes, or packed in soil, kept nearly dry during winter, they will now be starting into growth; therefore pull them into pieces, and each crown to which roots are attached will develop into a sturdy plant; in fact, it is better to use small rather than large plants, as the former make a more uniform bed. After dividing the roots place them again in boxes filled with rich sandy soil, or in a cold frame about 3 inches apart; water carefully until they have fairly taken possession of the new soil when more will be required, and also abundance of air to keep the spikes sturdy. They may be planted in their summer quarters early in May; the best position for them is in a bed by themselves where

they present a mass of rich colour. If the soil be fairly rich and water be applied to the roots should the weather be dry the flower-spikes will in most cases grow from 2 feet to 3 feet high, and if carpeted with Antennaria tomentosa the effect will be all that can be desired.—E. M.

Hollyhocks.—Sown a month since in a cool house, Hollyhock seed is now coming through freely, and I shall have plenty of strong plants to put out in a few weeks. It is well to be able to recommend sowing of Hollyhock seed in a cool temperature so early as the month of February. Very many may be induced to do the same thing, but are, as a rule, deterred when told that such seeds need bottom-heat to induce full germination. Of course this recommendation applies chiefly to seed sown the preceding year—rather too late, perhaps, in the autumn, but it would be even preferable, if possible, to sow seed in the month of August, and then keep the seedling plants dibbled up in a frame all the winter. Such plants would bloom and produce fine spikes during July and August; whilst spring-sown plants raised under glass and put out early should bloom during September and October. The quicker the plants make growth, the less liable are they to injury from the fungus which still haunts them. Hollyhocks thrive best in deeply worked soil, because they root deep, and need ample moisture. Plants left to grow in poor, shallow soils will produce but poor spikes or flowers, and if attacked by the fungus, soon wither up. As the best of quality, with great variety in colour in the flowers, can now be had in seedlings, it is obvious that for a trifle in money and trouble, a fine show of this old favourite hardy flower may be readily had.—A. D.

Lilies and their culture.—In the interesting notes on this subject (p. 230) allusion is made to the enormous quantities of *Lilium auratum* that are imported every year from Japan, and yet, says the writer, they are not to be found in our gardens in any quantity except in pots. And the question is asked, Why is this? From my own observations I am fully satisfied that it is owing in most cases to the Eucharis mite, as it is called, followed by fungi. This bulb mite is imported in the bulbs, a fact the truth of which anyone may verify by examining the bulbs on their arrival with a microscope. Those accustomed to look for this mite will have but little difficulty in finding it and eggs in abundance, and if the same bulbs are examined again after twelve months' culture, the cause of their break up and decay will no longer be a mystery. The question, however, naturally arises, How is it that *auratum* succumbs more quickly to the attack of this mite than other Lilies from the same country?—a question more easily asked than answered. *L. auratum* is grown successfully in Japan, though undoubtedly the mite exists there as the newly imported bulbs show. How, therefore, is that? Probably the vigour with which it grows in its native country enables it to keep ahead of the mite up to a certain age, and also obviates the attacks of fungi. Even in Japan after the bulbs have become old they may be liable to succumb to the mite. One thing is certain, viz., that the largest bulbs are those which break up and decay first; the smaller ones frequently go on for a second year.—T. KEETLEY, *Darby Abbey*.

Double Primroses.—These are now just bursting into bloom and a few pots dotted here and there amongst other things have a pretty and novel appearance. I should very much like to get the names of all the varieties that are at once fairly vigorous in habit and free-flowering, for the three sorts already tried, viz., the double sulphur, white and crimson, all do remarkably well and the collection might be extended with advantage. Two points to be guarded against in their cultivation are over-potting and coddling. With these borne in mind there is very little difficulty in working up some good plants, and the result is certainly very gratifying, for to the lover of old-fashioned plants there is nothing much prettier at this season than a few pots of double Primroses in different shades of colour, and with three or four dozen expanded blooms to each plant they make quite a nice display. To secure some good plants for an-

other season the old stock should be shaken out as soon as the flowers are over, divided, and the pieces potted rather firmly in small 3-inch pots. I find they do well in a compost taken from a heap of road-scrappings that have been once or twice turned. A mixture of light loam with the scrapings from the roads is a very suitable compost for them to grow in. When these pots are well filled with roots they should be shifted into 4½-inch pots, using the same compost. The best place for them all through summer and early autumn is a frame with a north-west aspect; the pots should be placed well up to the glass on a cool bottom and plenty of air should be admitted. On the approach of hard frost they may be shifted to a shelf in ainery or Peach house, where they may remain until required for the greenhouse.—E. M.

SHADED AND UNSHADED ALPINE AURICULAS.

THE season of the flowering of the Auricula is at hand, but keen frosts at night and hot, sunny days cause such extremes of temperature, that it is very trying to the plants that are in cool houses, and they make headway very slowly. Happy are they who can give their plants a little fire-heat by night, as most of our leading Auriculas want it now-a-days. It is not much warmth that is required, only just enough to keep the frost from laying hold upon the soil. So retarding are our springs now that it is almost impossible, without the aid of artificial heat, to have the plants in flower by the Auricula show at South Kensington the third week in April. Those who grow and flower only in a cold house or a cold frame are, of course, placed at a great disadvantage on a show day.

The later developments in the form of alpine Auriculas always hit the popular taste, and it is not to be wondered at, for they are very striking, especially those which have a golden centre. The contrast between the rich gold and the marginal colour, which is of various shades, is decidedly striking. In the north, among the older Auricula growers, the alpine Auricula, in order to be admitted to competition, must have a shaded margin, whether the centre be white, cream, sulphur, yellow, or gold. This is in contrast to the self-show Auricula, which, with its mealed centre or paste, must have an unshaded edge. Such a flower as Phoenix, for instance, one of Mr. Turner's most brilliant unshaded or self alpines, would not be admitted for competition at the National Auricula Society's show at Manchester. It is not so in the case of the exhibition in London, for there shaded and unshaded flowers are permitted to compete together, but a self Auricula, however good in tube and paste, if it had a shaded instead of a self-coloured margin, however beautiful it might be, is relegated to that singular and somewhat eccentric group termed "fancies." There is some inconsistency in this, and it is rather hard on those small growers who may have raised three or four fancy varieties of great merit, but who cannot exhibit them because in the class for fancies twelve dissimilar varieties must be produced.

The weakest class in the section of alpine Auriculas is the white-centred flowers. I do not know of a white centred alpine Auricula that has an unshaded margin. With a white centre is mostly associated shades of lilac, mauve, purple, and blue, and a perfect flower is among the fairest of the alpine Auriculas. We have very few perfect white-centred flowers, because the centre will be white or creamy white when the pip first expands, but it will either become a pale colour without a particle of the warmth of life and beauty in it, or else change to sulphur or some such shade, so that the flowers vary in the centre and have a confused appearance on the truss. But new additions are constantly being made to this attractive class, and slowly but surely permanent improvements are being effected.

The best of the white-centred alpines are Agnes, Duchess of Connaught, George Lightbody, one of the best; Lillian, Mrs. Dodwell, Mrs. Phipps, Princess Beatrice, Philip Frost, Queen Victoria, very pretty; Slough Rival, Selina, and Tennial, a lovely alpine when obtained in good condition. All the white-centred alpines are best when shown before the pips are fully matured, and ere they begin to show signs of

weakness in the centre. Conspicua, an old variety with large, bold flowers, is, when produced in refined character, a beautiful alpine, and is often seen in good character at Manchester. Some eight or ten years ago Mr. R. Gorton, of Manchester, raised a charming white-centred variety named Mauve Beauty, so named because of the delicate mauve shading in the margin; but the flowers were thin in texture and of delicate habit, and it was only occasionally it could be caught in the best character. I have raised seedlings from it, but up to the present have not reached to anything ranging much beyond the parental type.

The best dozen forms with golden centres and shaded margins will be found in Amelia Hartwidge, Brilliant, Diadem, a flower that is almost perfect in the margin when caught in its best form, but the centre, which is always weak in its gold, changes to a dull and dead-looking cream; Evening Star, King of the Belgians, one of the best shaded alpines with a golden centre Mr. Turner has raised, the rich, lustrous gold scarcely becomes dimmed with age; Lustre, Mrs. Ball, probably a seedling from Diadem, and having something of its weakness of centre—still, a beautiful alpine and worthy a place in any collection; Mariner, Mrs. Llewellyn, Sydney, Sailor Prince, Sensation, and Unique, the latter a beautiful flower, and a telling one in a collection, having large, bold, and finely-rounded pips.

Then of unshaded alpines, all with golden centres, there are Bright Star, Colonel Scott, John Ball, King of Crimson, Mercury, Mrs. Thomson, Phoenix, Spangle, Troubadour, Thomas Moore, Vesuvius, and Victorious. These include fine and striking varieties that are well worthy of cultivation, and among the freest growing of the alpine varieties.

Do not let anyone suppose that the varieties named in the foregoing lists are not hardy. They are perfectly hardy, but at the same time of such fulness of beauty that if planted in the open ground their qualities would be sadly disfigured by the storms and frosts of early spring, and yet I have seen alpine Auriculas planted out in the open on a raised border very beautiful indeed in spring when fine weather admitted of their charms being displayed. But a house or frame of Auriculas—the former is to be preferred because the grower can attend to the plants better in bad weather—is an object of great interest from the time the plants begin to be active in February until the time when they go out of bloom. And in such a house with the Auriculas can be grown many other species of spring flowering plants which can be tended in such a building, and their wants ministered to when it would be practically impossible in bad weather to open an ordinary garden frame and give the occupants the attention they need.

R. D.

Notes from Shirehampton.—The successful growing of *Lilium auratum* is so important a question, that I am anxious to know if anyone has tried growing it out of doors on the surface of the soil. Mr. Perry, gardener at Pen Pole House, grow some magnificent plants of it last year in pots in which the bulbs were half out of the soil. On the day I saw them every bulb had several fine strong shoots on it, and in some cases small bulbs around were throwing up leaves; they were in a cold frame. I should very much like to see this experiment tried in the open with a protection of ashes. *Camellia G. H. Hovey* sent here last year from America is in fine bloom—a dark red, also a large single pink-red with very flat centre of stamens, mostly pink. *Crocus imperati albus* is coming into bloom. Could you say if *Schubertia grandiflora* would bloom in a cool greenhouse? I see it is called a stove climber in a former number of THE GARDEN. We have had 18 in. of snow here. The Hepaticas, some 500 plants, were in fine bloom on Sunday last and I shall be glad to see them again. These were all raised from seed ten years ago by Mr. Frank Miles. *Iris stylosa alba* bloomed here in the open last month; the two blue varieties I have in abundance, but the heavy snow and slugs did them much injury.—C. O. MILES, *Sunnyhill, Shirehampton.*

Chionodoxa Luciliae.—We send a few spikes of *Chionodoxa Luciliae* from out of doors. These are from established plants. Considering the ground is covered with snow, we

think they are very good and the effect against the surrounding snow is most beautiful.—COLLINS BROS. & GABRIEL.

A beautiful gathering of this lovely spring flower. The blooms were quite fresh and not at all hurt by the recent severe weather.—Ee.

STOVE AND GREENHOUSE.

T. BAINES.

LAGERSTREEMIA INDICA.

AMONGST the different species of *Lagerstrœmia*, this is the only one that has come into general cultivation. It is an Evergreen, and blooms in summer, the flowers being produced in terminal panicles; they are different from those of any other plant with which I am acquainted; the petals, six in number, are twisted in a peculiar manner. There are two forms of *L. indica*; one bears flesh-coloured flowers, while those of the other are light rose when they first open, and afterwards they assume a light purple tint.

Cuttings treated in the usual way strike freely. They may be put in at any time when obtainable in right condition—that is, whilst the wood is young and soft; as early in spring as shoots can be had in this state is the best time at which to propagate, as then there is time for the plants to attain some size before the growing season is over. As soon as roots are emitted, dispense with the propagating glass, and after they have got sufficient hold, move them singly into small pots. Good fibrous peat that is calculated to last well, with some sand added, answers for this plant. For a short time after potting keep it in a growing temperature, shade when the weather is bright, but keep the little plants well up to the glass, and directly they have begun to move freely, pinch out the points of the shoots. It is necessary to attend to this in good time, as this *Lagerstrœmia* is somewhat inclined to spire up for a time without branching out enough to furnish the bottom sufficiently. Syringe freely overhead in the afternoon at the time of shutting up the house, and encourage growth by keeping the atmosphere sufficiently moist. In the course of the summer it will be necessary to give larger pots. The size of these must be regulated by the progress that has been made. If the plants have grown away freely, 7-inch or 8-inch pots will not be too large. Some rotten manure may now be added to the soil; pot moderately firm, keeping the atmosphere a little confined until the roots have begun to lay hold of the soil, when more air must be given. No fire-heat will be requisite from this time, but continue to make the best use of the sun's warmth by closing the lights in good time in the afternoon. Most likely it will be necessary to again stop the shoots, or at least the strongest portion of them, for on getting the heads well proportioned now depends the appearance of the specimens in after time. As autumn comes on discontinue shading and syringing, giving more air so as gradually to induce a state of rest; a temperature of about 45° will be enough in winter.

In March, cut the shoots in moderately; it is necessary to do this each spring, as the plant is a free grower, naturally attaining a height of something like 10 feet, which size, if the specimens are as they should be, proportionate in the spread of their branches, is much larger than is desirable for an ordinary greenhouse or conservatory. It is not needful that the plants should be allowed to attain inconvenient dimensions, as their character can be seen sufficiently when their size is restricted by cutting the shoots well in annually. After the branches have been thus shortened, it will be an advantage if a little more warmth can be given, as in a genial temperature the new growth will move more freely. When the plants have broken fairly, give pots 3 inches or 4 inches

larger, using soil of a like character to that advised for the last potting; afterwards, treat so as to encourage growth, affording plenty of light, and giving more air as the season advances. This summer, if all goes well, the plants will make a fine display; when in bloom they should have a thin shade, which will help to prolong the duration of the flowers. This *Lagerstrœmia* is very effective in a conservatory when in flower, differing, as it does, in appearance from everything else associated with it. It is a telling plant on the exhibition stage; why it is not more frequently used in this way seems strange, as it comes into flower in summer after most of the spring bloomers are over, which makes it more valuable.

Not the least of the desirable properties which the plant possesses is, that with anything like fair treatment it will go on for a number of years maintaining a healthy condition and flowering freely and regularly. As the specimens get older they naturally require larger pots. At the time of repotting a portion of the old soil should be got away, being careful not to carry this so far as to interfere much with the roots. Manure water applied during the season of active growth is an assistance. By giving it regularly at this time smaller pots will suffice.

To anyone who grows a dozen large specimen Fuchsias, and who has no more room to spare in his houses, I would say discard two or three of the Fuchsias and substitute two or three specimens of this *Lagerstrœmia*. Though they will not keep on giving a succession of bloom to the extent that the Fuchsias will, still the mass of flowers which they produce and the whole appearance of the plants are such as to make the change an advantage.

Azalea Mrs Carmichael.—This is one of the many varieties raised by intercrossing the hardy Japanese *Azalea amœna* with the large-flowered greenhouse section, and to a certain extent it partakes of the characters of both parents. It is of a close, free-branching habit, with moderate-sized flowers of a rich lilac-purple colour. From its affinity to *A. amœna* it is hardier than the members of that section known as Indian Azaleas, and on that account may be wintered in situations where the more tender kinds might be injured. For cut purposes it is well adapted, as it can be employed in the minor arrangements, where the large blooms of the other kinds would be inadmissible, and it bears cutting back remarkably well.—T.

Guelder Rose forced.—This may be successfully bloomed under glass, and very showy it is when treated in this way. Good-sized bushes, lifted from the open ground and potted carefully, will bloom well, but the best time of the year to lift them for this purpose is in the autumn, just as the leaves are about to fall. Standards are sometimes grown, and they may be employed with advantage for arranging with other subjects. It is not a plant that will stand hard forcing, but, brought on in a genial temperature, good blooms may be had by the end of March. Apart from its merits as a highly ornamental flowering shrub, this *Viburnum* will do well in almost any soil and situation, and can be readily increased by detaching rooted suckers, which after a year or two will form flowering plants.—H. P.

Rhododendron Daviesi.—This is a very showy greenhouse *Rhododendron*, and interesting as being the result of a cross between the rarely seen *R. retusum* and *R. javanicum*. There was a variety put into commerce some years ago claiming the same parentage under the name of Prince of Wales, but, judging by our plants, *R. Daviesi* is superior to it in brightness of colouring, and more particularly in the freedom with which it flowers. The variety under notice is very free-growing, but liable to run up naked during its earlier stages, to prevent which it should, when young, be pinched back pretty freely. The leaves are of a dark green tint, and the colour of the flower is a bright orange-red. The individual blooms are

not large, but, being borne in good-sized clusters, form a very attractive feature when fully expanded. Like all hybrids that claim parentage from *R. javanicum*, this succeeds best in a temperature rather above that of an ordinary greenhouse. It is now, and has been for some weeks, in full flower.—H. P.

Centropogon Lucyanus.—This is a quick-growing stove plant of easy culture, whose great recommendation is the fact that it will flower continuously throughout the winter months. The blooms are claw-like in shape, and of a bright crimson-scarlet colour. They are borne in considerable numbers, and yield a goodly display during the dull days of winter. Cuttings of it strike root easily enough, and to ensure a good crop of bloom they should be grown on liberally throughout the summer months, and by autumn will be full of flower-buds. Being a liberal feeder, a dose of liquid manure occasionally will be of service.—T.

CROSSING AMARYLLIDS.

MR. H. NEHLING asks whether or not *Amaryllis* and *Crinum* cross with each other. This I have tried, but never got any pods of seeds to form. Different species of *Crinum* cross with each other, as do different species of *Amaryllis* and *Hippeastrum*, but the two genera seem to be totally distinct from each other. Dean Herbert cultivated numerous species and varieties of both, and raised hybrids from both of them, but he does not give any instance of a cross having been obtained. There is no other book so useful in its way, nor more carefully written than that of Herbert. He enumerates about 225 species of *Amaryllis*, *Hippeastrum*, and *Crinum* alone. The hybrid Mrs. Garfield, figured in THE GARDEN, is not included amongst spring flowering varieties. It is an autumn-flowering kind, and is a cross between two distinct species, one parent being *A. reticulata*, with the whitish band in the centre of the leaf. No coloured plate of the best garden varieties of the spring-flowering *Amaryllis* has as yet appeared in THE GARDEN. A monograph of the *Amaryllis* would doubtless be popular with growers, but if illustrated with coloured plates the expense would be too great. Recent improvements in the genus have been so great, that even the varieties named by Mr. Nehling have been surpassed. *Madonna* is superior to *Enechantress*, which is lacking in form. *Empress of India* has been greatly improved by seedlings raised from it. It ought to be generally known that seedling *Hippeastrums* are as easily raised as those of *Pelargoniums* or *Cinerarias*, and it does not take long to get them up to the flowering stage. It is difficult to obtain seeds of the choicest kinds. They will neither cross with other varieties, nor can they be fertilised with their own pollen, varieties raised by crossing distinct species being the most difficult to manage. Of these I might mention *H. Chelsoni*, a fine variety raised by crossing *H. pardinum* with another species, and *John Heal*, a hybrid doubtless from *H. Leopoldi*, which it resembles, but is greatly superior to it. *Empress of India* is one of the best of seed and pollen-bearers. I saved sufficient seeds from one plant of this variety in one season to produce 700 plants, and the bulb was none the worse for it; it even flowered stronger the next and following seasons. J. DOUGLAS.

Violet failures.—Why should one man succeed and another fail in getting plenty of Violets in winter, both having the same convenience, the same sorts, and residing within a score of miles of each other? This is a question to which a satisfactory answer would be instructive. Not a few growers of Violets incur displeasure because they cannot manage them so well as someone else in the neighbourhood. I am only what I may call fairly successful with Violets; we have had them all winter, but not in such abundance as some growers would lead us to believe they have had them. We have been able to pick several bunches two and three times a week, but I should imagine from what I have read that this is an insignificant quantity, although continuous since last October.

I am therefore anxious to learn what the conditions are which secure such success. Here in Somerset, such varieties as *Marie Louise*, *Comte de Brazza*, and *Neapolitan* can only be kept in flower in substantial brick pits under efficient external coverings during frosty weather. It is not unusual for us to lose a few plants during winter, and after damp, foggy weather a good many leaves damp off, but I have never heard of any great amount of mortality amongst Violets. I have known them, however, to run to leaf and to produce but few flowers. It is desirable in writing about Violets to state whether they are growing under glass or in the open.—J. C. C.

Double flowering Rhododendrons.—A few of these are now in flower in Messrs. Veitch's nursery at Chelsea. A double white variety with flowers like a *Tuberosa* is very noteworthy, as well as a double yellow. The interesting part of these crosses, all of which have been effected by Mr. Heal, who has done so much for the *Amaryllis*, is the fact that out of the same pod of seed, plants have been raised which, on flowering, produced white, yellow, salmon, rose, and other coloured flowers.

Waterer's Cherry forced.—*Cerasus Watereri* is not what one would call an uncommon shrub, yet there may be many readers ignorant of the fact that it is one of the loveliest shrubs imaginable when forced into bloom about this season. Its flowers are produced so thickly on the long spreading shoots, that they make these look like wreaths of delicate pink rosettes, for the flowers are double and as large as a crown piece. There is no shrub that can be forced that has such a lovely delicate colour, which may be said to be a compromise between *Peach blossom* and *white Cherry blossom*. It is not too late to get plants of it now, which are kept in pots at nurseries for the convenience of forcing. They must be gradually inured to the heat, and in a few weeks every strong shoot will be covered with bloom. The beauty of this *Cherry* out of doors is fully recognised in some places, but for every *Waterer's Cherry* one sees there are a score of *Almonds* and *Peaches* in shrubberies and on lawns.

Begonia Princess Beatrice.—This *Begonia* as a bedding variety is not only the best of its class for that purpose, but has the double merit of being a winter flowering kind. A small bed, consisting of about a dozen plants, bloomed profusely during last summer until the middle of October. They were then taken up, carefully potted, and placed in a Muscatinery, where in the *Grapes* were hanging, and which was kept a little warmer than an ordinaryinery. Thus treated, they flagged but little, sufficient water being given to prevent them from becoming quite dry. By Christmas new growth was made, and early in January the plants commenced to flower, which they have done abundantly ever since, and from their appearance at present they seem likely to go on blossoming for some time longer. As the flowers are quite white, having lost that delicate blush shade which they have outside in the summer, they are very useful. Lately they have had a temperature of 50° by night and a rise of 10° by day.—E. MOLINEUX.

Cyclamens at Twickenham.—It was a specially interesting sight which I met with in Mr. Richard Clarke's Twickenham garden the other day. Here, where *Cyclamens* are grown in vast quantities and of the finest quality, I found a truly grand lot of crimson in such quantity that it was quite a surprise, for in days past deep colour, although general, has not been found in appreciable quantity and allied to robustness. Mr. Clarke seems to have developed rich colour specially, and how telling a body of well-bloomed plants at this time of the year is when the flowers are of a deep rich crimson, the Twickenham plants show. Presently we shall find seed of this rich strain plentiful, and then we may hope to see plants plentiful also. Mr. Clarke's very fine *giganteum compactum* strains have been so often referred to, that nothing new can be said about them. The entire strain, including all forms and colours, is a very fine one, and every year, as out of so many plants the range of selecting the best for seed is very great, through constant selection the strains

are being improved. The Cyclamen is now so good, that progress in improvement must be but slow. It was exceedingly interesting to note in the larger houses thousands of fine plants ready for market, and many exceptionally fine; whilst in low houses were vast quantities of seedling plants yet in bulk in pots fast becoming ready for single shifting; the seedlings of to-day become the flowering crop literally of to-morrow.—A. D.

SEASONABLE WORK IN PLANT HOUSES.

RHOPALAS AND ARALIAS.—These plants are useful for associating with large-flowering specimens of any kind in greenhouses and conservatories. Not the least of their merits is that the texture of their leaves is such as to offer little inducement to some of the most troublesome insects to attack them, the juices of the Rhopalas especially appear to be too acrid to suit the tastes of these pests. Their leaves are of an enduring nature, but in time the lower part of the stems get naked, in which case they have an unsightly appearance that can only be rectified by heading them down. This is best done at this time of the year, as they at once break and begin the formation of new heads. If the stools can be accommodated for a time in a house or pit where a moderate amount of heat is kept up, this will accelerate the growth. To give the future heads of the plants the requisite appearance, the young growth must spring from not more than some 6 inches or 8 inches above the collar. In heading in any plant the roots suffer a check proportionate to the extent to which the leaves, branches, and stem are removed; consequently, instead of heading down to the bottom at first, if 2 feet or 3 feet of the old stem are left until the young growth has begun to move freely, the progress made during the season will be greater. To force the stools when so treated to break as low down as required, it is necessary to cut out all eyes from the upper part of the old stem thus left for a time. These and similar habited plants look best when confined to a single stem; consequently the shoots that appear should at once be reduced to one, retaining that which is the strongest; after it has attained a height of 12 inches or 15 inches the old stem may be cut down to where the young shoot springs from. This way of treating the plants in question and others of a like character will effect a gain that overbalances the little extra attention which it entails. The larger the plants are the more heading down affects them when the whole of the head and stem is removed at once; in the case of such they often come away both slowly and weakly.

CLIANTHUS DAMPIERI.—This is one of the most telling plants in cultivation, but, nevertheless, it is seldom met with. This no doubt arises from the fact of many who attempt its cultivation not succeeding with it. It is easily raised from seed, which, treated in the ordinary way, usually germinates readily, and generally afterwards makes fair progress until the time for shifting the seedlings into larger pots arrives, when it not unfrequently happens that the plants will not move further. So far as my experience goes with this, the finest of all the Clianthus, the cause of its refusing to move is through the objection it has to its roots being disturbed. In place of sowing a number of the seeds together in a pot or pan in the ordinary way, they should be put singly into 3-inch or 4-inch pots, and before the plants get too much cramped they ought to be moved to others two or three sizes larger, placing the ball intact in the new pot, not even removing the drainage material, and following a similar course when the shift is given into the pots the plants are intended to flower in. I have known this Clianthus do well when the seed was sown in a bed, allowing the plants to remain and flower where sown; but this method would not answer in the plant houses usually met with in private gardens, where, if a bed exists that plants can be grown in, it is generally much too far from the glass for this or anything that requires from the first to have plenty of light. The same objection, only in a less

degree, exists against turning plants out in beds that have been raised in pots. Seeds of this Clianthus may now be sown in moderate warmth, keeping the plants on in such until the weather is hot. Plants raised from seed last year should now be moved into the pots in which they are to bloom. After the weather gets warm the syringe ought to be used freely to keep down red spider, which is sometimes troublesome, and if left to go on unchecked soon injures the leaves.

GREENHOUSE CLIMBERS.—It often happens that climbers of an over-strong, coarse habit of growth are planted in conservatories and greenhouses with the result that unless their tops are allowed to extend so that they smother or injure everything that is grown under them, it becomes necessary to keep them cut in to an extent that gives little chance of their flowering much, and in the case of such things as *Cobaea scandens*, some of the *Kennedias*, *Bignonias*, and others of a like description, the character of their flowers is such that not much can be said in their favour, especially when there are so many fine kinds to choose from. When a large, roomy conservatory is first built it is often desirable to plant something in the way of climbers that will take off the naked appearance of the roof in the least possible time; but when for the sake of immediate effect such a course is taken, other climbers of a better character that are less rampant in their growth should be introduced at the same time to take the place of the inferior sorts, gradually reducing the heads of the latter as the better kinds require more room. For small, or comparatively small houses, such sorts as the following are much more suitable than larger growers, *Rhynchospermum jasminoides*, *Sollya Drummondii*, *S. heterophylla*, *Solanum jasminoides*, *Passiflora Imperatrice Eugénie*, *P. Constance Elliotti*, *Lapageria alba*, *L. rosea*, *Acacia verticillata*, *Clianthus magnificus*, *Hibbertia volubilis*, *Jasminum grandiflorum*, *Habrothamnus Newelli*, *H. aurantiacus* (*Cestrum aurantiacum*), and *Asparagus plumosus*. Several of these will cover a considerable space if their roots are not somewhat confined, but with judicious treatment in this matter and a moderate use of the knife, they can easily be kept within due bounds without their ability to flower well being interfered with. For a medium-sized structure may be mentioned *Acacia pubescens*, *A. longiflora magnifica*, *Clematis indivisa*, *Habrothamnus Newelli*, *Lapageria alba*, *L. rosea*, *Mandevilla suaveolens*, *Tacsonia Van Volxemi* or *T. exoniensis*, *Tecoma jasminoides*, *Bignonia capensis*, *Mutisia decurrens*, *Passiflora Newmanni*, *P. Constance Elliotti*, and *Asparagus plumosus*. Several of these are included amongst the kinds recommended for a small house, but under liberal treatment they attain size enough for larger structures, and, moreover, their merits are such, that they deserve a place wherever climbing plants are wanted. In large conservatories, such sorts as the following are suitable: *Bignonia Chamberlaini*, *B. Tweediana*, *Clematis indivisa*, *Lapageria rosea*, *L. alba*, *Kennedyia macrophylla*, *K. coccinea*, *Mandevilla suaveolens*, *Tacsonia Van Volxemi*, *T. manicata*, *T. mollissima*, and *Habrothamnus Newelli*. The latter is a finer kind than the better known *H. elegans*, being much brighter in colour. The climbers here named are not given as an exhaustive list of all that are worth growing, but, collectively and individually, they are much superior to many one meets with, some of which have little to recommend them, except that they serve to take off the bareness of the roof or wall. In preparing beds or borders wherein to plant climbers, it is necessary to keep in view the more or less vigorous habit of the plants to be used, restricting the root-room somewhat where the intention is not to encourage more growth than will suffice to keep the plants in a healthy condition; and in all cases it is well to partition off the border, so that the roots of each will be confined to the space that they are meant to occupy. If this is not done, the strong growers naturally monopolise the whole of the material, so that the weaker ones are starved. Wherever alterations of the kind here intimated are to be carried out,

the work should be done at once, so that a full season's growth may be secured.

MAGNOLIA CAMPBELLI AND M. FUSCATA.—Where there happens to be a high back wall in a conservatory or greenhouse, these two species may be used to clothe it with good effect. They bear fine distinct-looking flowers, white in the first-named kind, and brown in the latter; and the presence of the plants does something to lessen the monotony too often met with in plant houses of an all but endless repetition of the same things. These *Magnolias* are both natives of China, and do not require anything more than a greenhouse temperature. *M. Campbelli* is deciduous, whilst *M. fuscata* is evergreen. All they require is a border of moderate extent, sufficiently drained to keep the soil in a healthy condition, and their principal shoots secured to the wall, so as to cover the space to be occupied, leaving the lateral growths as much freedom as can be done without their encroaching upon the other occupants of the house. T. B.

GARDEN FLORA.

PLATE 589.

DAY LILIES.

(WITH A COLOURED PLATE OF *HEMEROCALLIS DUMORTIERI**)

THE *Hemerocallis*, or Day Lily, as it is called from the fugacious character of its flowers, in some of the species lasting generally only one day, is nearly allied to the *Funkias*, a well-known class of plants largely used for naturalising in woods, &c. The Day Lilies, though numbering not more than five distinct species, are varied enough, both in their habit of growth and flower colouring, to be useful alike in the mixed border, the rockery, and the wild garden. In a situation such as the last in all its natural wildness few sights equal a strong, well-flowered clump of *Hemerocallis fulva*, as we have seen it in all its native luxuriance judiciously mixed with a group of male Fern in close vicinity to a small brook. The leaves of this Lily were overhanging the banks of the stream, intermingled with the Fern fronds, while the flower-heads, tall and straight, were towering well upwards. If the ground is well broken up and some good lasting manure supplied at planting time, they may be left undisturbed for years. The forms of *H. disticha*, both single and double, are also useful for this purpose, either in isolated clumps or intermixed with other robust or bold-foliated plants; indeed, there seems no reason why all the members of this genus could not be treated in this natural way, the trouble entailed being small, and that chiefly at planting time only. For cutting purposes, *H. flava*, minor, and *Dumortieri* are especially useful, the flowers lasting a few days and the buds opening well in water. The fragrance of these flowers is most delightful, and on this account alone they should find a place in every garden. They are readily increased by division of the roots in autumn; indeed, they grow with such rapidity, that in the course of a few years they may be increased to almost any extent.

The following are the species as they are now recognised with the principal varieties:—

H. DUMORTIERI (*Dumortieri's Day Lily*).—This rare and valuable garden species, of which a good figure is given in the accompanying coloured plate, is the first to flower of all the Day Lilies yet introduced to cultivation, and when it becomes better known is likely to prove a great acquisition, even in company with the already much admired *H. flava*. Coming as it does from Japan and Western Siberia, it proves perfectly hardy in the open air in this country, besides having a great advantage over most

* Drawn for THE GARDEN by H. G. Moon in Mr. Herbst's nursery at Richmond, and printed by G. Severeys.

of the other showery Liliaceous genera, inasmuch as fair success can be attained even in ordinary garden soil without any special preparation. It does not require protection of any kind during the winter season, and we have never known it to fail to produce an abundant display of its charming and fragrant flowers, which are not unlike many of the other Lilies in these respects. The individual blooms are unfortunately short-lived, but this is fully compensated for, as the reserves are so numerous as to keep up the succession for a considerable time after they begin. Like most other allied plants, the Day Lilies seem to dwindle both in the vigour of the plants and size of the flowers if allowed to remain too long in one place. If the plants are examined, the centres will be found to be firmly matted together, the stronger shoots appearing on the outside. If the whole plant is divided and spread out it will amply repay the trouble by increased vigour and display of bloom. It is closely allied to *H. minor*, also known as *H. graminea*, but it is a much stronger plant, however, with leaves twice as broad, the flower-stems short, and the divisions of the perianth divided almost or entirely to their base. The leaves are about five or six to a growth, about 18 inches long and half an inch broad, narrowed to a point, bright green above and pale, but not glaucous on the under surface; flower-stem 1 foot to 2 feet in height, bearing a corymb of few or many large orange-yellow flowers; introduced about 1870. *H. rutilans* and Sieboldi of gardens belong to it.

H. FLAVA (the yellow Day Lily).—Few plants that we are acquainted with, and that can be so successfully grown with so little trouble in the ordinary mixed border or flower-bed, give such a valuable return as this one. Not only are the flowers large and delicate in tint, but they are produced in such quantities, emitting such an agreeable fragrance, as to earn the title of *yellow Tuberosa*. It appears from the older writers that this plant was considered only as a variety of *H. fulva*; and Parkinson observes that "it agrees with *fulva* so nearly, as that it might seem to be the same; but the leaves are not fully so large nor the flower so great or spread open; the colour is a fair yellow wholly; it is very sweet, and it abideth blown many days before it fades." The length of time the individual flowers remain before fading considerably enhances its value as a border plant; indeed, we consider it so choice that we would strongly advise its being planted out in large conservatories, and even as a pot plant its delightful perfume would amply recompense the grower. In the open air, however, it is perfectly hardy, and though not so robust in habit as the following species, it increases with average rapidity, and where the soil is good might even be naturalised in the wild garden. On the rockery it has a natural appearance, the beautiful light green curving leaves hanging gracefully over the boulders, surmounted by bunches of large yellow heads of flower in June and July. It is a native of Siberia, Hungary, Istria, &c., and was cultivated by Gerard. *H. Thunbergi* and *japonica* are forms of this species.

H. FULVA (the copper-coloured Day Lily) is a more robust and much larger plant in all its parts than *H. flava*, and consequently more suitable for extensive planting in semi-wild or neglected portions of the garden or woodland. It seems to be variable under cultivation, and the numerous forms now grown, many without names, are all worthy of attention for the above purpose. Though variable, none of the forms with which I am acquainted would suggest any relation to *H. flava*, as the following is intended to imply: Professor Martyn, editor of Miller's Dictionary, relates the following rather curious experience of a lady near Aylesbury—"In the year 1788 she removed several plants from Hampstead to a new garden she was then making in Buckinghamshire. The soil was a stiff clay manured with pond mud, sand, and manure in some parts; in others it consisted of the ruins of buildings and limestone, mixed with a soil produced from a variety of animal and vegetable substances. The plants were first placed in the clayey soil, among them being a plant of *H. fulva*. The succeeding year she divided this plant, and put part of it in a shallow bed formed of the limestone compost. It grew very freely, so that she

was able to take off another part of the plant, and the same summer set it in the same bed. When the last plant flowered she was agreeably surprised with the sight of an *Hemerocallis flava*, which she is positive she was not possessed of till it was thus produced by accident. The year after she had plants varying in size and colour, large, and of a deep tawny hue, small and absolutely yellow, and also of a pale tawny and of a size between *fulva* and *flava*." This, if it be true, would seem to favour the idea of their being varieties; but it is just a little suspicious that nothing of the kind has been noticed in our own day, the two plants being perfectly distinct even when grown side by side, as we have seen them for a great number of years. *H. disticha* is a well-known garden variety of this species, notable for the fan-like form of its growths. The flower-stem is forked near the summit, and carries two or three heads of flowers, six to eight blooms on each, of a brown-orange colour. There is also a double-flowered variety of this. *H. Kwanso* is a variety with variegated or striated leaves. It is a handsome plant for edgings or for the rockery. Of this there is also a double-flowered form. *H. f. var. angustifolia*, narrow-leaved; *longituba*, *crocea*, &c., natives of China, flowering in July and August, belong to this section.

H. MIDDENDORFIANA is a comparatively new species from Amurland, and has not yet found its way into general cultivation. In general appearance it nearly resembles *H. Dumortieri*; the leaves are, however broader, the flowers about the same size, closer, and paler in colour, and with a distinct cylindrical tube half an inch or so long. It is of easy cultivation, and the gracefully curving bright green leaves and pretty delicate flowers give it a unique place even among its fellows.

H. MINOR, also known in many gardens under the highly characteristic name of *H. graminea*, from its Grass-like foliage, was formerly classed by the older botanists as a variety of *H. flava*, though now considered distinct enough to warrant a separate place amongst the others of this genus. It is the smallest, though by no means the least showy, and, like *flava*, sweetly scented, the individual flowers lasting two or three days before decaying. They are large, yellow, and produced in much the same way as the others. It makes a handsome subject for rockery decoration, and even when flowers are absent the pretty Grass-like leaves recurving from about the middle give it a distinctness quite its own. It was known to Gerard and Parkinson, and said to be one of the many plants introduced to gardens by Dr. Sibthorp. It flowers during June and July, and is a native of Siberia, &c. It is also known under the names *graminifolia* and *pumila*. D. K.

FRUIT GARDEN.

W. COLEMAN.

SHADING FRUIT HOUSES.

THE rapid progress made by the present generation of growers of exotic fruits in a great measure is due to improved ventilation, full command of top and bottom heat, and a profusion of sunlight. The transition from the old to the modern systems of building and glazing, when immense squares of inferior sheet glass took the place of small panes, whose every lap let in a stream of fresh air, was not only extremely trying, but it brought into general operation the baneful practice of systematic shading. At that time gardeners could not well avoid the use of clumsy materials for breaking the fierce heat of the sun, as almost every square was thickly studded with inequalities, which formed as many lenses capable of burning the stoutest foliage, and not infrequently the stems and branches of fruit trees. Down to this period but little progress was made, as the loss of the fine percolations of air over every part of the roof, and the absolute necessity for shading, rendered sound, healthy culture difficult, high-coloured and richly-flavoured fruit being exceptional qualities. Intelligent fruit growers then, as now, knew that the

important changes which take place in the secretions of fruit are due to heat, light, and the free admission of fresh air, but until the tariff was entirely removed, the element which costs us nothing could not be allowed full play upon our hothouses. This burning or scorching period, whilst covering the sheet-glass manufacturers with ignominy, was not, however, an unmixed evil, as it was the lesson thus taught which brought about our present perfect system—I may say systems—of ventilation. Good sheet glass, free from inequalities, fit for picture-glazing, can now be obtained at ridiculously low prices, and this, it is hardly necessary to say, has rendered one of the gardener's greatest nuisances—daily shading—a bugbear of the past. Slight shade at certain times and under extraordinary conditions is, of course, necessary, and always will be, but, given a forcing house well glazed with the best British sheet, and ventilated upon the most approved principles, there must indeed be something radically wrong in the mode of culture where systematic shading is still resorted to.

At one time within my own memory a blink of sunshine caused a rush to the Pines, the Cucumbers, and even the heat-loving Melons, and so deeply were the results of five minutes' neglect impressed upon young gardeners' minds, that it is by no means surprising a remnant of the system is occasionally met with. Hartley's patent rough plate-glass, which is said to destroy transparency without diminishing translucency, was ushered in as a remedy for every ill, and notwithstanding the fact that it has made considerable headway amongst plant-growers, it has never found favour with growers of fruits that are natives of countries whose temperature is much higher than that of our own. Before the thousand-and-one light gossamer shading materials, running up from Haythorn's netting to scrim canvas, were invented, common whitening and lime, reduced to the consistency of paint by mixing with hot water, linseed-oil, and skim-milk, were used for shading the roofs of houses and the man who could manufacture a storm-resisting paint was hailed as a benefactor. Plant and fruit growers still living can tell us how the *Stephanotis* and other plants refused to flower under their baneful influence; how thousands of Peaches became whitewashed, not by the shade, perhaps, but by the lime mingling with the tankfuls of soft water from which the trees were syringed. I do not for a moment condemn the judicious use of light shading, neither do I think plant or fruit growers can entirely dispense with it; but to young men whose aim is a profusion of blossom or full crops of highly-coloured fruit, I would say think well before you resort to systematic shading. Keep your glass clean; keep the interior of the house as clean and sweet as a living room; ventilate freely by day and give a chink of air at night; and, above all things, allow vitiated air to escape by opening the top lights early on bright mornings. With two instances of the result of systematic shading, one upon plants the other upon fruit, I will close this paper.

When a young beginner I had charge of the finest *Stephanotis* I have from that day to this seen. It covered the back wall of a hip-roofed Pine stove, and the foliage was magnificent, but constant shading and incessant drenching kept it in constant growth. Shoots that would have formed a girdle round the garden were cut out annually, but the flowers were conspicuous by their absence. Under this mode of treatment is it matter for surprise that people in these days even jump at the conclusion that there exists a non-flowering variety of *Stephanotis*? The other lesson was learned in a Muscat house. Imperfectly ventilated and with a trellis too near the

glass, a set of well-planted Vines became badly scorched every summer. Annoyed by their unsightly appearance, the head gardener decided upon the use of canvas, which was tacked on in the spring and remained until the following autumn. This extended from the eaves slightly above the line to which the young canes were shortened back at the winter pruning. The buds, notwithstanding the scorching of the leaves, had ripened well and produced good bunches of Grapes, which, owing to want of light, never coloured properly. The wood of the same year made in the full blaze of the sun ripened in a satisfactory way, and for a time we lived in a fool's paradise, but, as many of your readers will premise, our joy was of short duration. The following season the young leaders were shortened back to within 3 feet of the upper margin of the shading of the preceding year, and the buds on these short lengths of wood produced good shows abundantly. Below the line, *i.e.*, the shaded portion, the breaks from the spurs and the lower parts of the young rods were weak, and not a single show was found upon one of them; indeed, so marked was the failure that one could tell to an inch how far the shade from this light material had extended. This, it is hardly necessary to say, was the first and best lesson I ever learned in the art of Muscat growing. To some I may appear in the light of a Job's comforter, but common-sense facts are stubborn things, and I still maintain that more may be learned from the record of one thoroughly investigated failure than half a dozen successes.

GRAFTING.

We are just now on the eve of the grafting season, and those contemplating practice will do well to be prepared with scions. Too many who wish to graft trees otherwise useless or not of sufficient merit to retain have found a season lost solely because they omitted to provide themselves with the needful grafts at the proper moment. To work with prospect of success tree growth should be a little in advance of the scions, and if these have been taken from off the parent trees and laid into the soil as if ordinary cuttings, they will remain dormant even after all tree growth has pushed freely. No doubt trade growers provide themselves with an ample stock of grafts seasonably, but grafting is much less resorted to in the case of young stocks than formerly, and budding is preferable wherever possible. Buds must be full of excitement at the time of insertion, and union with stock and bud soon results. Were that not the case, the bud would soon perish. On the other hand, a graft has so much of body and of hard wood in it, that it will endure for some two or three weeks in an active state, even though union with the stock be not effected. When the stock is in fit condition for grafting the scion is the same, and if the work is properly performed, without doubt the uniting process follows rapidly. After all it is just possible that the condition of the stock has most to do with the rapidity or otherwise of the process of union, for grafts are not easily killed until the season has considerably advanced. Whilst seasons and situations must govern the time for grafting appreciably, yet the middle of April is, on the whole, about the most favourable time. In the case of stout stocks it does not at all follow that the heads which are to be removed need remain on the trees till so late a period. If cut some 6 inches or so above the point at which the grafting is ultimately to be done, even during the winter, the stem will not appreciably suffer, and if freshly cut clean off lower down just when the grafting is desirable, the stem will probably be found amply supplied with sap. Of course very much depends upon the extent and condition of the roots, but as grafts cannot for several weeks absorb all the sap created, it is evident that too powerful a flow early is not desirable. Later, when the union is perfect and

growth has resulted, the sap force can hardly be too strong, as a vigorous growth from the scions the first year means the foundation of a fine tree-head later. There are literally tens of thousands of trees from five to fifty years old in the country which would be all the better for, and indeed would soon well repay, beheading and grafting. We have an immense number of Apples trees, for instance, but how many of them either fruit sparingly or produce fruit that is almost worthless? How many, too, have become literally cope heads, so thick that pruning or thinning is a work of despair, and even if done would hardly be remunerative. In all such cases it is wiser to take the heads off to clean stems, and re-graft with some other productive and meritorious kinds. The beheading does not check the root action of the tree; whilst the re-heading by grafting literally gives renewed life and vigour to trees previously thought only fit to grub up. The robust growth on the tops allied to healthy and vigorous leafage reacts upon the roots—inspires them, as it were, with renewed activity; and conjoined, a fine, productive tree-head soon results. When so served, orchard or garden trees have a start which no newly-planted young trees can hope to overtake. A stout stem, say 6 inches through, will easily take four strong grafts as big as a man's finger; and each one, throwing the first year three stout shoots, forms a big head at once, which in three years becomes a large tree. Then fruitfulness follows quickly also, for the root and head force is soon equalised. Of course, much then depends upon the sorts worked, as some are so much the more precocious than others, and some so much the more prolific, especially early kinds. We must not, however, be too anxious to give up everything good in fruits for the sake of securing precocious or free-fruiters. We want some which will give us late keepers, high flavour, fine form, or other qualities having special market value. There is so much room for development, in Apple culture especially, that too much stress can hardly be laid upon the importance of re-grafting old and apparently worthless trees. A very odd-looking object certainly is a newly-grafted tree which has some seven or eight branches all worked. After all, it is very doubtful whether that is the most desirable plan to adopt. As a rule, I think a clean stem some 4 feet or 5 feet from the ground to be preferable, in the case of standard trees, to many branches worked higher up. In the former case some four or five stout grafts only can be employed, but the sap force is concentrated, and the growth all the more robust; the resulting head later becomes the most handsome, whilst one the product of many branches always presents an ungainly appearance. The work of grafting is simple enough, and when done not too far from the ground, is very easily performed. A clean part of the stem is selected, and a clean cut with a saw made, so as to obviate the tearing of the bark. A sharp knife is drawn from the top of the stem 4 inches or 5 inches in length, and clean through the bark, in as many places as the grafts are to be inserted. A specially prepared piece of wood, pointed and flattened like one side of a clothes-peg, is prepared, and driven in behind the slits in the bark to open it. The grafts, stout and of clean, vigorous wood, bevelled on one side to fit the opening made, are driven well in, and then are secured by a bandage of stout bast, then clayed over, and finished off neatly. Carefully done, the result may be looked for with entire confidence. A. D.

Protecting fruit blossoms.—Unlike Mr. Hobday's trees (p. 233), our Apricots and Peaches are fully three weeks or a month earlier than last year. Our first Apricot bloom opened on February 28, and that of our first Peach about the 8th inst. On the 11th we were visited by a severe snowstorm, followed by sharp frosts, which have continued more or less now for more than a week. Notwithstanding the severe weather, however, our Apricots are merely protected by fishing-nets, but these, when folded two or three times, afford a considerable amount of protection both from frost and cold winds, and up to the present time the blooms do not appear to have suffered

much. For Peaches we have canvas, rolled up in the morning on bright days and let down in the evening; but where fishing-nets are used they are not removed at all until the fruit is set and all danger from frost is over. Before the severe weather set in Pears with us were very forward, some blooms being nearly expanded; these we protect by means of fishing-nets; likewise Cherries, and where small standards or bush trees have a good show of bloom on them, they should be protected by placing three or four stakes around them and throwing a piece of canvas over them at night. If this were done many disappointments would be avoided.—OLIVOR.

HARDY FRUIT CULTURE.

It is pretty generally admitted that the less pruning Peach trees want in spring the better; it cannot, however, be dispensed with altogether. The thinning out of exhausted wood and the shortening back of strong leading branches are a necessary part of the spring management of Peach trees; cutting out wood not wanted should, however, have been done before this, and taking off the tops of the leading shoots had better be deferred until the trees are in bloom, or at least until the buds have swollen up sufficiently to enable the cultivator to readily distinguish fruit buds from wood buds at the point to which it is desirable to cut back. This is of more importance than the inexperienced would imagine, because Peach trees in vigorous health form so many buds, that before they begin to swell in spring it is difficult to decide whether they are fruit buds or wood buds. If there should be only flower buds at the point to which any shoot is to be cut back and no wood buds below it, which is not at all unusual, especially in the case of large-flowered Peaches, that shoot will be useless, because there being no wood bud to form growth, it will ultimately die. In all doubtful cases as to whether there are wood buds or not, it is better to defer pruning until the flowers are open, and then, if there are no wood buds, the shoot can be left the whole length, as there are invariably wood buds at the end, or it can be cut out altogether. No one need apprehend any danger to the crop or the tree from pruning when the trees are in flower. Of this I am certain from my own practice, both in the case of trees on open walls and those under glass.

Thinning the bloom on Peach trees is not so often practised as it might be. It is more necessary perhaps to do so in the case of trees under glass than in the open, but in all cases where there are double and treble buds one will suffice to furnish a crop, provided those buds which are not wanted are removed as soon as they can be handled, because it must be evident the remaining half must be better nourished, and consequently in a better condition to resist unfavourable climatic conditions than would be the case if all the flowers were left to open and fall from the tree in a natural way. In the treatment of Peach trees on open walls most people are advocating more root moisture than has hitherto been allowed, and also biennial lifting or root-pruning. These measures are not being taken any too soon, for but in very few instances have the trees received the amount of attention which they require. In many cases the roots have been permitted to find their way down into ungenial soil, while others in well-drained borders have suffered from want of water, and not unfrequently have the branches been so much crowded that it has been impossible for the wood to get ripened even in the most favourable seasons. In the case of outdoor Peaches, deep and rich borders must give place to borders composed wholly of good loam and not more than 2 feet deep. Manure of any kind, except as a surface dressing, should be altogether dispensed with. The question of drainage, too, must be considered, and our views on the necessity of draining all borders alike regardless of the character of the soil must be modified. It is possible to drain too much. My own experience leads me to believe that draining fruit-tree borders is only necessary in a very limited number of cases. The roots

should be kept near the surface, where they can have the benefit of the sun's warmth. Lime in some form or other should, it is thought, be present. But I, however, happen to know of a garden in which chalk has been used for surface-dressing Peach borders annually for several years past. In this case the chalk has to be conveyed seventy miles by rail and three miles by road, but the Peaches are no better in this case than in others in which no chalk or anything approaching the character of lime has been used. I am, therefore, of opinion that lime is not a necessity for the successful cultivation of the Peach. I have met with quite as many failures in the chalky soils of Surrey and Sussex as I have in soils of a wholly different character.

For Plums and Pears high walls and wide borders are considered to be needful, but these the character of the soil should decide. If the soil should be of a kindly, friable nature, such as an experienced fruit grower would consider suitable for these fruits, and of a depth of, say, 3 feet, then I say high walls and wide borders are desirable, but where conditions are unsuitable I am equally confident that the walls should not exceed 10 feet in height and the width of the border should be 8 feet. This will place the trees under what I may call a moderate system of restriction, and I am satisfied that is the only safe rule to follow when the roots have not a wide run in a favourable soil. While the roots can find an agreeable medium the trees generally remain fruitful, but there are miles of low walls in the country furnished with trees to the top which are every year bare of fruit because the roots have been allowed to remain down in an ungenial soil. The result would have been no better had the walls been twice the height, but if the roots had been restricted in proportion to the space covered by the branches by being occasionally lifted out of the bad soil, results would have been more satisfactory. High walls in conjunction with wide and deep borders are desirable, because when it can be prevented, both Pear and Plum trees are the better for not being severely pruned, but when circumstances make it a necessity satisfactory crops over a long period must not be expected, unless the roots are prevented from getting down into an unkindly subsoil.

Disbudding fruit trees is an operation that will soon claim attention, but in a general way it is commenced too soon. In a laudable desire to relieve the tree of an unnecessary amount of growth we are apt to lose sight of the fact that the said growth affords a certain amount of protection to the young fruit. I have many times observed that more fruit is lost after the crop is set than before, a circumstance which I think shows that the young fruit is more tender than the flowers, and as the leaves are developed soon after the flowers fade it is plain that they are intended to act as protective agents; therefore to remove them too soon is to deprive the fruit of some of the protection which Nature has provided for them. When, then, is the proper time to disbud? So far as my experience goes, I should unhesitatingly answer that the first week in June was soon enough to disbud any tree on open walls, but Peaches and Nectarines should take precedence after that date, and then should follow Apricots and Plums, and if the results are compared with seasons when the work has been done earlier, I am sure it will be found that it is better to disbud late than early. J. C. C.

Unheated vineries.—In southern parts of the kingdom the practice of growing Grapes in unheated houses is rapidly spreading. The demand for Grapes is greatest in autumn when seaside towns are full of visitors, and the supply from unheated houses can be sold before the damp, dark days of early winter render fire-heat necessary to keep the crop from getting mouldy. The main point is to secure a good sunny aspect, and a light, well drained soil favours early ripening. In some parts of Sussex the soil is naturally so well suited for Vines that cuttings of them are put in without any more ground prepara-

tion than would be given to a plantation of bush fruits. After they have got strong a slight wood-work structure just enough to carry the glass is run up over them, and really good crops are thus secured in a short time. Expensive borders and lofty vineries have been thrown quite into the background. Span-roofed houses with a row of Vines on either side are in favour with many, but I think the lean-to form is decidedly the best, as it retains heat longer than any other form. The chief cultural point is to keep the Vines as cool as possible in early spring, so as not to excite them to grow while the nights are very cold. Plenty of air is given both night and day up till the time when they can be no longer retarded; then, in order to economise sun-heat as much as possible, they are shut up early. It is surprising how much sun-heat plants will bear if their foliage is dry, but in the morning when it is wet with dew, scalding readily takes place. We therefore ventilate early and shut up early. Very little syringing is done in these cold houses, damping the floors being enough to create an amount of moisture capable of maintaining healthy growth. The roots are allowed plenty of space inside or out in which to ramble, and plenty of good surface mulching is given them, and also liquid manure when the crop is swelling. The Black Hamburg is the greatest favourite, and Foster's Seedling makes a good white companion for it, but of late the demand for white Grapes has been but limited. By being close to the market, fruiterers or growers in this district manage still to compete with imported fruit even at 1s. per lb. These cool-grown Grapes in no way interfere with either very early or late keeping crops grown in properly heated structures. Good early Hamburgs directly the latest Alicantes and Gros Colmars are finished always realise good prices in limited quantities, but the bulk of the Grape crop is cleared off at very low prices, and must therefore be produced by utilising the sun's rays to the utmost, thus saving fuel for crops that realise a higher figure. —J. C. C.

The Plum crop.—Notwithstanding the heavy crop of Plums which we had last year, the promise at the present time of another full crop this season is very bright, the trees being wonderfully full of fruit buds, from which the winter covering of brown scales has already fallen, and a sprinkling of white spots is showing on even the smallest twigs. Even on a north wall the Victoria variety never fails with us, and the same may be said of the purple and yellow Magnum Bonums. But the most satisfactory trees are some upright cordons which are growing on a west aspect and which are about 10 feet in height; these were lifted and replanted late in the autumn of 1885, an operation which had become necessary, as they were too vigorous to bear fruit. We had therefore no crop from them last year, but now every branch is bristling with fruit buds from top to bottom. Lifting the roots had the desired effect in a larger measure than I had anticipated, for instead of the trees making long, stout leading shoots they made great numbers of small ones which are now full of fruit buds. —J. C. C.

SHORT NOTES.—FRUIT.

American Apples.—The business of exporting Apples, says the *Anti-American Times*, is increasing. Two years ago 220,000 barrels were shipped from New York; in 1885, 302,000 barrels; and last year, 349,000 barrels.

English grown Newtown Pippins.—Mr. Goodacre recently sent me some extra fine fruits of the Newtown Pippin grown on a south wall at Elvaston Castle, Derby, which, though lacking the rich yellowish green colour of imported fruits, were quite equal to them in crispness of flesh and flavour. This Apple is proverbially bad in this country; indeed, I have never before seen presentable home-grown specimens of it, but if it does so well on a wall in Derbyshire, it is certainly ought to do equally well in the orchards of Kent. —W. H.

Inarching by means of pot Vines.—J. D. (p. 19) gives a correct description of this kind of inarching. Last year I inarched some dozen Vines on this plan, having the previous year succeeded in establishing some very fine fruiting rods. The pieces left in the pots make excellent plants either for fruiting in pots or for planting out. I propose this summer to pot inarch some dozen Muscats. The results of this kind of inarching are very fine fruiting rods the same season; in some cases I have the next year cut 40 lbs. of Grapes from them. —STEPHEN CASTLE.

Pear Beurte Roland.—From the *Bulletin d'Agriculture* we extract the following: This variety, raised by the late M. Roland, schoolmaster, Grosse, Hamault, first fruited in 1851. It is of medium growth, and very suitable

for cordons and bushes. The fruit is of medium size, obovate, the stalk short, deeply inserted; the eye very small, closed, skin somewhat rough, pale yellow, covered with patches of brown russet; the flesh is firm and melting. It ripens in March, and is a very heavy cropper.

SEASONABLE WORK AMONG FRUITS.

Down to the present time our hardy fruit prospects are unusually promising, and, provided the passing away of the snow, of which we recently had 6 in., ushers us into genial spring weather, trees of all kinds will produce a glorious blossom. What the outcome will be it is impossible to divine, as trees protected by walls cannot be considered safe until after the 20th of May, and if the old adage that every frost in March is followed by three in May comes true the coming flowery month will be the most remarkable on record. Fortunately, we have neither the time nor the inclination to meet trouble midway, and as fruit trees generally are well ripened and the flower-buds are bold and plump, but decidedly late, our present business is to leave no stone unturned, but to strive manfully in devising means for their protection. The first enemy we have had to circumvent is the beautiful, but daring bullfinch. At one time he commenced a terrible onslaught upon Plums, Pears, and Gooseberries, and, contrary to our usual custom, we syringed twice instead of once with a wash of soot, lime, and soapsuds. Still he persevered, and a wash of alum, some time ago recommended by a correspondent, was tried, only with partial success, and, last of all, a quantity of old nets cast loosely over the trees most terribly touched his dignity. At once he took his departure, and to show how dwellers in wooded districts suffer, I am truly sorry to have to record the fact that the tenant of a small Cherry orchard has shot more than one hundred. Our Gooseberries, after all, are well furnished with buds, and soon they will be out of danger.

APRICOTS,

still looking well, are making slow progress, and the effect of 19° of frost, followed by 6 inches of snow upon the sap vessels, remains to be discussed another day. Being more precocious than Peaches, although barely in flower, we begin to feel anxious about them long before the latter claim our concern, and when all has been done for them they are 75 per cent. less profitable than Peaches. Non-protectionists so far have the whip hand, as they have saved a certain amount of trouble, whilst the stoutest woollen materials would hardly save the conservator's expanded flowers from the frosts which have prevailed since the 1st of March. A very small remnant of late flowers, however, sometimes forms a crop of fruit, and it is not yet too late to premise the conservator will win. In a very practical paper Mr. Hobday recommends evergreen branches for protecting fruit trees, and I can endorse all he has said, but unfortunately this method in some districts is not quite satisfactory. Here, for instance, the south-west winds sweep up a valley from the Channel, and no matter how carefully the boughs are tied and tucked in much damage has been done by chafing. The plan I now adopt is equally homely. I do not believe in coddling and canvas, and answers in my case much better. For each wall I have sets of smooth Larch poles, with a short piece a foot in length nailed to the top nearly at right angles to prevent them from resting against the coping. The poles are inserted a few inches in the border, 3 feet from the foot of the wall and 9 feet apart. A broad board weighted down to the stone coping and with a nail through it into the top of each pole completes the framework. From the edge of this projecting board two or three thicknesses of fishing net are dropped, and tied to the poles about 2 feet from the ground. A man and boy can cover 50 yards in a day; the nets and poles admit of our walking along the enclosed space, which is more or less dry; the boards prevent cutting draughts, and the weather must be unusually severe if we miss having a good set of fruit. I have often thought that west walls are the best, and south walls the least favourable to the culture of Apricots, and this Blackthorn

winter, with a continuous run of frosts ranging from 10° to 19°, strengthens the opinion that more fruit would be obtained in the long run. At this time the sap in trees on south walls is very active, and all the early flowers are killed, while trees on a west aspect are ten days later and comparatively quiet.

PEACHES.

We are now, this 19th of March, protecting our wall Peach trees with broad copings and fishing nets. They give wonderful promise, no bud dropping, thanks to ripe wood and two liberal supplies of water through the hose. These trees facing full south will now have to fight their own battle with the elements, as more cannot be done for them. Newly purchased and transplanted trees on a west wall have been well mulched and watered, but the knife remains in the sheath, and training will be deferred until they show unmistakable signs of making growth. It is to be regretted that our leading nurserymen do not keep a good supply of all the best sorts of Peaches and Nectarines on 2-foot stems, *in situ*, worked on the Mussel or the Brompton at that height from the ground. Half standards can be made out of dwarf maidens, but then the union is near the ground and the stem formed of Peach wood is tender and more liable than the Plum to be paralysed by severe spring frosts. I have paid particular attention to this matter for a great number of years, and can safely say short standards are hardier, more fruitful, and last longer than dwarfs. The most striking proof of this I have experienced over and over again in the two fine late varieties, Walburton Late Admirable and Barington, which give great satisfaction when worked upon 2 feet to 3 feet stems.

STRAWBERRIES.

Where the formation of new plantations is contemplated the ground should now be ready, but the transfer from nursery beds need not be made until the middle of the coming month. The dry season has been highly favourable for trenching and getting the land into fine tilth, a very important matter where it has to remain undisturbed for a period extending over three years. As spring plants cannot be expected to give fruit of any value, we always pinch out the flower-scapes and crop this well-prepared piece of ground with successive sowings of Cos Lettuce. The seeds are sown in shallow drills, the young plants are thinned to 16 inches apart, and no matter how dry the season we are never without large crisp Lettuces.

If the old beds have not been trimmed, thoroughly cleansed, and dressed off, this work may be taken in hand as soon as the weather breaks. When all troublesome weeds have been taken out with a small hand-fork one or two dressings with old soot will induce slugs to change their quarters and prove an excellent stimulant. When new soot is used, heavy dressings over the crowns of the plants should always be avoided. Some few cling to the barbarous practice of forking between the rows of these and Raspberries, but this destroys all the most useful roots, when the bulk and quality of the crop are greatly diminished. When the top-dressing is levelled down a good soaking of water will be of great service on warm, light soils, as we have had but little rain of late, and, judging from the way in which open quarters turned up when winter dug, these moisture-loving plants will need sufficient to penetrate the subsoil. Many people water these and fruit trees later on, but often miss their mark, giving the roots a full supply to start with.

Planting.—If this was not brought to a close in the autumn, fair success often attends planting early in April. With large trees there is of course considerable risk, but, provided they are puddled in, well secured, and mulched, young trees hardly feel the moving. I do not recommend spring planting, but there are few places in which this work is not thrown back, as was the case last autumn, and when this unavoidably happens the first appearance of returning life is the safest period to fix upon. If not already brought to a

close, every tree in garden and orchard that has not been well mulched should at once receive attention. Good manure in a half decayed state is generally considered the best mulch for fruit trees, but on cold heavy soils naturally rich enough to force good growth, it is questionable if better results may not follow the use of other materials. Here I give preference to finely broken lime rubble as a first dressing for stone fruits, and burnt refuse for Apples, Pears, and bush fruits. Where all the prunings and trimmings and a fair proportion of heavy soil are systematically reduced by fire, the ash or potash makes fruitful spurs and wood where strong manure forces rank growth which does not always ripen.

THE ORCHARD.

Work in this department can always be found. In this part of the country it is a standing dish to which all fruit growers can turn and return with advantage to the trees and benefit to their pockets. During the first spell of severe weather we laid to with spade and grub axe in a large orchard composed of vintage and choice old culinary fruits, and after heading back a few of the most promising for grafting retired, as we thought, for the season. A change to deep snow and sharp morning frosts, however, again finds us letting in more light and air, as it is folly to think of obtaining good table fruit from trees that are suffocated by wildings. The great fault in many orchards is crowded planting and allowing the trees to grow into entangled masses of spray and useless timber. Many of these trees are past their best, but half a loaf being better than none, thinning, trimming, and top-dressing will often renew the lease until such time as new plantations can be grown into bearing. Grafting and renovation are matters to which occupiers must pay personal attention, but new plantations should be made by the landlord. Men whose interest only extends from year to year cannot be expected to find capital for this work, as they may be called upon to give up before the trees produce a blossom. Once properly planted, yearly tenants who cannot make corn pay will find Apple culture fairly remunerative; but why not grant sound intelligent men in fruit districts long leases? Fruit growers at the hurriedly got up show recently held at Chester have proved that fruit rooms the first week in March were much better stocked than the most sanguine pomologists anticipated. Further, faulty as many of our fruit rooms are, the autumn and early winter sorts so well represented conveyed convincing evidence that sound keepers can be kept long beyond their allocated season. So far our progress is satisfactory, but to make Apple growing pay we must have quantity as well as quality; we must place ourselves in a position to turn out thousands and tens of thousands of barrels of fruit throughout the spring months weekly. Growers have shown that they have the ability; the ways and means now rest with landowners and legislators, who must bestir themselves if they wish to keep at home a portion of the money which we now pay to foreign fruit growers.

Planting.—Although autumn is the best time to plant, healthy young trees, especially if they have been formed or grown for a year in the home nursery, may be planted throughout March. The main precaution, as I have just pointed out, is puddling in, good mulching, and firm staking in a way that will prevent rocking, chafing, or straggling by the gradual settling of the soil. Hitherto easy-going people who could afford to plant for the rising generation put off from year to year where all details did not dovetail to a nicety, but speed is now the order of the day, and our fruit culture having fallen so sadly into arrear, my advice is to push on the work where the trees and soil are in suitable condition. Grafting, owing to the lateness of the season, will also be late, as the condition of the stock, not any particular period or date, must guide the operator. Young stocks generally are worked in March and April; old trees often up to the end of May. Of two periods, provided heading back and the selection of scions preceded the rising of the sap, it is better to be a

few days late than too early. Yearling shoots are used for small stocks, and clean, stout, two-years' wood is preferred for large orchard standards. To the uninitiated, grafting, like many other operations, may appear very difficult, but such is not really the case, as any man who is handy with his tools can soon learn the art; when to operate is gained by watchfulness and past results. What to graft is another matter, which must be governed by the varieties doing well in the district, by the situation, and, as a matter of course, the purpose for which the fruit is intended. On reference to Mr. Bunyard's excellent little book, "Fruit-growing for Profit," which, by the way, every grower should purchase, we find our Kentish leaders dividing Apples into four sections, *viz.*, early dessert Apples, to sell direct from the trees; culinary or "smashing" Apples, to sell direct from the trees; dessert Apples, for storing; and culinary sorts, for storing. These lists are very comprehensive, and might be quoted here in detail, but the price of the book is only 1s. 6d., and being so full of thoroughly practical information, not only upon Apples, but upon every kind of hardy fruit, the most experienced man will not regret perusing it for himself. For private use, selections may, of course, be made from each section, but the early and late sorts should be extensively planted for market.

W. COLEMAN.

FERNS.

W. H. GOWER.

TRICHOMANES AT KEW.

This genus consists of a large number of elegant plants, having for the most part extremely delicate, pellucid fronds; hence Filmy Ferns, a name by which they are popularly known. The collection of these plants just now at Kew is both extensive and excellent as regards health, and but for the fact that they are encased with dull green glass, they would afford a rich treat to all lovers of Ferns who visit that establishment. *T. alatum*, from Trinidad and Jamaica, is one of the best of them. It is a free-growing and elegant plant, with ovate-lanceolate, pale green translucent

Trichomanes arifoliatum.

fronds from 6 inches to 12 inches long; the pinnae are united to the main stem by a narrow wing, and the segments are deeply pinnatifid, the cup-shaped involucre being immersed. *T. crispum* is a distinct and handsome form with fronds from 6 inches to 9 inches or more in length, bright sea-green in colour, and the stems are clothed with tawny hairs; the fronds are once divided, the segments being oblong-obtuse, often so closely set as to overlap each other; the involucre is situated in

the points, immersed, but the hair-like veins which bear the sori are exerted, giving the edges of the fronds a fringed appearance. It comes from Jamaica and various other parts in the West Indies and Tropical America. *T. Leprieuri*, better known as *T. anceps*, is very plentiful in Trinidad, and is also found in Dominica and Brazil, and is one of the largest and finest species, growing from 1 foot to 2 feet in height; in the typical form the fronds are triangular in outline, the first divisions being pinnate, but afterwards they are several times pinnatifid; the spore cases, which are situated on the margins, are bell-shaped and pendulous; the colour is a very dark metallic green. Another very handsome form of this plant, also from Trinidad, has broadly ovate, acuminate fronds of the same intense blackish green colour, with all the divisions very much larger and broader than in the type; we have also seen a form from Dominica in which the fronds are oblong in shape, and the segments are still broader than in the previous variety. The caudex is erect and stout; naturally it appears to grow in loamy clay, but under cultivation it does not thrive in this material. It requires a somewhat higher temperature than that in which most of the other kinds succeed. *T. pinnatum*, sometimes called *floribundum*, on ac-

oftener plain, each bearing a terminal immersed involucre. In direct contrast to this curious little plant comes *T. trichoideum*, which may be utilised in similar positions. It grows freely and forms dense clumps of delicate fronds, which are usually from 2 inches to 6 inches high, but some specimens from New Grenada show that they attain there a height of from 9 inches to 12 inches; the fronds are bright light green and three or four times divided, all the divisions being minute and thread-like, through which the little erect black cups show themselves prominently. This is one of the most delicate and charming of the whole family, and widely distributed throughout the West Indian Islands. In *T. Luschatianum* we have a bold, robust plant of scandent habit, which forms a beautiful object if allowed to grow upon the stem of a Tree Fern. It may be described as a climbing *T. radicans*, with sessile fronds some 12 inches or 18 inches long, and with broad, deeply-divided segments of a rich deep green; it comes from Brazil. *T. auriculatum* is a native of Java. It is of scandent habit, and produces large, rich, bright green fronds, the ultimate segments of which are broad and deeply lobed, bearing on the edges the small exerted involucre. *T. exsectum* is a native of Juan Fernandez and Chiloe. It has a slender creeping stem, and bears

we found good specimens of nearly all the species in cultivation growing in an unheated brick frame in the back yard attached to his dwelling-house, the necessary protection in cold weather being afforded by a covering of tiffany. More recently we observed in Sir Trevor Lawrence's garden at Boxhill good clumps of *Trichomanes radicans* (the Killarney Fern) growing in nooks in the Odontoglossum house without any covering; whilst their adaptability for room decoration was strikingly exemplified by the late Mr. Cooper Fester at his London residence. The kinds with creeping rhizomes delight to ramble over tree stumps or rockwork. Under cultivation the latter is preferable, as it does not decay, and, moreover, retains a cool, moist, equable temperature, whilst those having a tufted growth and erect stems should be planted in crevices of rocks or stones, from which there is a free outlet for water; the interstices should be filled in with nodules of peat and Sphagnum Moss. In a wild state many of these plants appear to thrive in stiff yellow loamy clay, but we have never been able to maintain them long in a healthy condition in such soil. In arranging a case for Filmy Ferns we prefer moderate-sized blocks of sandstone to any other material. These should be set in an irregular manner, straight lines above all things being avoided. When the plants have been placed in the positions desired, the whole should be settled down by means of a sprinkling of water from a fine-rosed watering-can; such sprinklings should be repeated from time to time as may be necessary in order to maintain that genial moisture-laden atmosphere which is so essential to the well being of these plants. The situation should be such as to prevent the sun shining upon them at any time during the day. If such a spot is not procurable, then some light shading material must be provided for them while the sun is upon them, but by all means avoid the use of green glass.

Trichomanes reniforme.

count of the dense fringe which its exerted involucre form round the edges of the pinna, is also a Trinidad plant, which, like the preceding, does not thrive in a cool temperature. It is tufted in habit, and produces pinnate fronds a foot or more in length; these are of two kinds, the infertile fronds being broad and imbricated and much toothed on the edges; these are of a bright, lively shade of green, the apex of the frond being proliferous. The fertile fronds are not so, and the pinnae are much narrower, densely fringed on the edges with a single row of little, erect-stalked, cup-shaped involucre, and the veins are exerted. *T. olivaceum*, a native of Venezuela, is generally considered a form of the variable and widely distributed *T. pyxidiferum*; it is a free-growing plant with a creeping rhizome, which soon covers a block of sandstone or stump of a Tree Fern with its elegant deep green fronds; these are some 6 inches or 9 inches high, and two or three times divided into narrow segments, which render the partially exerted vase-like involucre to be very conspicuous. *T. Petersi* should be fastened to the face of a block of stone, over which it will soon ramble and clothe with verdure. It is a native of Alabama, and its fronds are less than an inch in height; these are entire, oblong-lanceolate in shape; sometimes it is serrate on the edges, but

fronds from 6 inches to 12 inches high, all the segments of which are very finely divided. *T. reniforme*, from New Zealand, is a similar departure in form in this genus to that of *Adiantum reniforme* amongst Maiden-hairs. It has a thin, wiry, creeping stem, and produces large kidney-shaped fronds which measure nearly 3 inches across; these, which are borne upon footstalks from 4 inches to 8 inches high, are thick and leathery in texture; when fertile (which under cultivation occurs but rarely) the involucre form a dense and conspicuous edge round the margins. When the fronds are not fertile they are more undulated than in the case of those grown in its native habitat. Of *T. venosum*, another New Zealand kind, we noticed nice specimens, also good examples of *T. radicans* (the Killarney Fern), *T. membranaceum*, a kind with a sea-weed look, and *T. maximum*, besides numerous other kinds.

THE TEMPERATURE of the house in which the Filmy Ferns at Kew are grown is kept at about 55° during the day, and is allowed to fall some 5° lower at night. There can be no doubt that the majority of *Trichomanes* thrive best in a low temperature and moist atmosphere—a fact clearly demonstrated a few years ago in an amateur's collection of these plants in Bermondsey, where

KITCHEN GARDEN.

W. WILDSMITH.

SALAD VEGETABLES.

GARDENERS one and all will, I think, agree that in order to produce a regular unbroken supply of salads more skill and forethought are required than are needful in any other branch of kitchen gardening. To obtain good and constant supplies of Lettuces, Radish and Mustard and Cress, seven months out of the twelve is an easy matter under ordinary open-air modes of culture; but in order to continue the same over the other five months—from November to the end of March—there must be frame space, and if the variety required be large, that space must be considerable. Presuming, therefore, that there is no lack of frames, and that only the following most generally required kinds of salad plants are needed, namely, Cucumbers, Lettuces, Endive, Radishes, young Onions, Chicory, Dandelion, Mustard and Cress, by strict attention to sowing at stated or regular intervals, a full supply at all times may be reckoned upon almost as a certainty. During winter Cucumbers are fitful, and sometimes refuse to succeed, no matter how well they may be cared for, but these constitute the only element of uncertainty, and when they do fail, it is, as a rule, near the end of the year, so that by making a prospective sowing about the middle of November in expectation of such an event the break in the supply need not be a long one, for seldom, indeed, do young plants fail to thrive when planted early in the new year if afforded a bottom-heat of 75° and a top-heat of from 65° to 70°. For late autumn and winter fruiting the seeds should be sown by the middle of August, and the young plants planted out in the beds of the Cucumber house by the middle of September. Should they show a disposition to bear before they have extended over two-thirds

of the trellis, the fruit should be picked off in order to get strength into the plants, and this operation will probably prevent premature exhaustion—fruiting to death of plants—before the most trying time has been reached—the dark, short days of November and December. These plants should continue fruiting till well into spring, a second lot of young plants being grown on in the meantime in another division, or part of the one division, to succeed these, whilst throughout the summer and autumn the supply may be obtained from frames, and the Cucumber house may be utilised for the growth of Melons; Telegraph is the variety to be preferred to all others. Everybody knows when to sow Lettuces for summer and autumn use; therefore winter supplies are all that need be alluded to. The first sowing should be made in the second week in August; this will ensure good Lettuces being cut from the open border till quite the end of November, and the next sowing made in the third week of August will produce plants for lifting, with balls of earth attached to them, for planting at the base of south walls and in frames. It is well to make a third sowing in September, and plant the produce out under handlights or in cold frames to succeed the plants lifted, and put in frames after they have completed their growth. For all these sowings there is no better variety than the Black-seeded Bath Cos. The colour—brown—may be objectionable to some, in which case Hicks' Hardy White Cos should be substituted. Endive is not a popular summer salading in this country, but it is invaluable all through the autumn and winter, and when well blanched there is no other ingredient of the salad bowl that equals it in appearance. The first sowing of this should be made in June, another in July, and a third early in August. These three sowings will generally be found sufficient. Part of the produce of the first sowing will probably be obtainable from the open borders, but a much better plan and one that ensures perfect blanching is to tie up, not over tightly, the whole of the plants, and plant them quite closely together under the shelter of walls, and where, if needs be, mats might be quickly thrown over them for protection from frost. The later sowings should all be lifted and be put in frames about the middle of November, and be tied up for blanching as required, or, better still, be lifted from the frames and put into the Mushroom house or any other dark frost-proof place, at intervals and in quantities as may be required. Moss curled and Broad-leaved Batavian are the most generally approved varieties. Supplies of Radishes can only be had good during winter by sowing in frames placed over slight hotbeds composed of leaves and stable litter. Open garden supplies, as a rule, are obtainable till well into October, so that the first sowing in frames should be made a month previous, and successional sowings at intervals of three weeks up to the end of the year, when the supply may be continued by sowing a few between the rows of Potatoes that are being forced in frames. The French Breakfast and Wood's Early Frame are the best varieties for forcing, and also for the earliest open-air supplies. Young Onions for the most part are preferred to Chives, and as a very small quantity is required for each salad, by sowing a small box in heat, say, half-a-dozen times between September and February, a never-failing winter supply may be kept up, and from that time—February—frequent sowings on a warm border are the best way in which to obtain supplies throughout summer and autumn. Any variety can be made to do duty in salads. Chicory and Dandelion are both highly prized for winter salads, and as they are of the easiest

possible culture, there is really no difficulty in having good supplies of them. Sow the first week in April in drills a foot apart, and thin out the plants to 9 inches asunder in the row. They will be ready to lift by the end of October, when they should be stacked in sand and stored in a cool place. Pot the roots, or plant them out in the Mushroom house in such quantity as may be required, and at varying intervals. To have the leaves well blanched, perfect darkness is essential. No note need be made about getting constant supplies of Mustard and Cress other than that during winter in but moderate heat it is necessary to sow once a fortnight. Celery, Tomatoes, and Beet, though used as salads as well as vegetables, are more frequently used separately; therefore, they hardly come under review in a general salad list.

Market Carrots.—Owing doubtless to the somewhat clayey nature of the soil in West Middlesex, Carrots as a market crop are not largely grown, although it is certain that very good samples may occasionally be produced, especially of the Intermediate forms. It is possible a further explanation for the non-production of Carrots here may be found in the apparent ease and cheapness with which they can be grown in Surrey, and especially in localities where soil is favourable and much cheaper rented than in Middlesex, and on this account Carrots can be offered at much lower prices than they can be grown here. The other day I purchased a real old-fashioned bunch of a dozen handsome clean Long Surrey Carrots in a local shop for the trifling sum of 3d. Of course the getting up, washing, sticking, and tying, besides loading and sending perhaps from thirty to forty miles to market, meant much labour, in addition to which there were market dues and the local shopkeeper's profits, who resides some sixteen miles from the London market. What the grower really received in the first place per bunch it would be interesting to know, but hardly more than 1d. per bunch. Very probably these same carrots would in a London shop, where rates, rents, and taxes are so heavy, have been priced at 6d. a bunch. As far as I am concerned, however, there is no room for complaint, and it is not a matter of surprise if the Middlesex men decline to compete with the Surrey Carrot growers.—A. D.

Globe Artichokes.—Our plants covered with short litter are, I find, all right, but where unprotected the probabilities are that many will die, and those not killed outright will be late in starting. Even where well protected this year they will be late in consequence of the protracted winter. Where there are plenty of sound roots of a moderate size, the result of frequent transplantation, a few may now be lifted, divided, potted, and brought on in gentle heat. If hardened off and planted out in May, they will bear earlier than those left out altogether, but the roots should not be cut up too much. It is best to leave a good piece of the old root-stock attached to the offsets, as under such circumstances less check is sustained. If there is reason to believe that the old plants are seriously injured by the frost, it may be advisable to sow seeds in order to raise a new stock, though seedlings, as a rule, unless the seeds were carefully saved from a good variety, are often of inferior character. Whenever I have raised plants from purchased seed, some portion has always been inferior, producing small, light, prickly heads of no value. Seeds saved, however, from selected heads of the purple-tinted variety have generally come pretty true. If the seeds are sown now in heat they soon germinate, and when potted off into single pots they rapidly acquire strength, and by the middle of May, or perhaps earlier, they will be strong plants in 5-inch or 6-inch pots ready to plant out. They should be grown on in a warm house or pit till within a few days of the time when they are to be planted out.—E. H.

SHORT NOTE.—KITCHEN.

Transplanting boxes.—Mr. Harwood, of Colchester, sends us a specimen of what is called a transplanting box, which has a removable bottom. We object to mechanism of all kinds in the garden. Any man who knows how to move

a plant can do so very readily without any mechanism, and all such things as transplanting boxes with removable bottoms, and flower-pots with wire "lifts," are unnecessary.

PROTECTING BROCCOLI IN WINTER.

Most growers will admit that there is much uncertainty attending the cultivation of Broccoli. Taking into consideration the fact that this crop generally occupies the best position in the garden, as well as some of the best soil, during six or nine months in the year, it is disappointing to find at the end of that time that one's labours have resulted in a very inadequate return. Yet for many years such has been the case, and this season forms no exception to the rule, for most of the crops of Broccoli that have come under my notice, and which were once so promising, are now blackened and for the most part destroyed through the severity of the weather, all kinds having suffered about alike. One would have thought that, owing to Broccoli being such an indispensable vegetable, gardeners would have been able to lay their hands on some more hardy and trustworthy sorts than at present exist, but such is not the case. True, there are plenty of varieties, far too many, for half-a-dozen would be amply sufficient, provided they possessed that one desirable property, hardiness, but that is still a desideratum. My experience is that Broccoli intended to stand the winter is often overgrown; kinds of medium size and sturdy growth pass the winter much better than such as are more succulent. A too rich soil for Broccoli is often disadvantageous, as it renders the plants soft and pithy, and thereby more liable to injury than they otherwise would be. Hard ground moderately enriched and plants set at a greater distance apart than is usually the case are the best preventives of injury from frost, and yet after all these conditions, if carried out, will only partially save a crop. We must therefore resort to other means of doing so, such as providing some suitable protection. The following facts in connection with this part of the subject may be worth recording: A plantation of several sorts of Broccoli had to be taken up early in November to make room for some greenhouses; I therefore had a trench dug 5 feet wide and a good spade's depth, throwing the earth half on one side and half on the other to form banks; the plants were lifted carefully with all the earth attached to the roots they would carry and were laid in this trench, in which the roots were covered with the loose earth left at the bottom; they were placed at convenient distances apart, and made firm in the soil by treading. Thus circumstanced, they were allowed to remain until frost set in, when the occurrence of the banks on each side enabled me to lay some supports across, on which I laid rough litter sufficient to protect the Broccoli to some extent from frost, though not enough to keep it entirely from them, for they were sometimes frozen. By taking the litter off at short intervals and admitting light and air I saved the principal part of my crop from destruction, while if the plants had stood where first planted I fear I should have lost them all. This circumstance leads me to think that until we get a good hardy Broccoli it would pay where it can be done to devise some means of protecting the sorts we now grow of this useful vegetable. THOMAS RECORD.

Kitchen garden edgings.—Variegated Ivy makes a good permanent edging in connection with stones which it covers. I have seen the stone edging lifted without disturbing the Ivy much, and the walks relaid with asphalt minus the stone edging; therefore the asphalt came close up to the Ivy, which was clipped in so as to form a straight edge. After laying down the asphalt, some white and red gravel was sprinkled over it to make it firm. This made neat and firm walks and looked well in connection with the Ivy edging. Some might perhaps object to Ivy on the ground that it harbours slugs and the labour needed to clip it, but it did not appear to harbour more slugs than Box, and as regards clipping it is much easier

done than that required by many edgings. I have seen walks edged with a turf about a foot in width, and when kept clean and neat, right well it looks. But for well-kept gravel walks Box is my favourite.

—OLIFOR.

Potato planting.—Because soils were working so admirably, Potatoes were being planted very early, growers naturally taking advantage of the fine, dry weather. Tubers, of course, find the ground cold, and not conducive to early growth; hence it is just possible that they may prove even more restful planted than if kept in store. Judging by the excellent crops often found from self-planted Potatoes, it is naturally concluded that early planting conduces to the same result. It is doubtful, however, whether more self-planted tubers are not destroyed during the winter than live to grow, and equally with very early planted tubers it is possible that between cold soil, vermin, and danger from early frosts after growth is made that more come to grief than if planting was done a month later. Under ordinary conditions a good average planting time for early kinds is about the end of March. Of course in the open ground, as in warm borders, planting may be done much earlier. No real test seems to have been made as to the relative values of plantings in March and in April, but as in the latter case, assuming the soil to be of equal character, growth is the more rapid, it is very possible that the April plantings would be the most productive. Still, no one can blame growers for promoting planting so early when weather is so unusually favourable and soil in such admirable condition. Over large breadths the dibber still remains the favourite implement for planting, and when employed by an expert it is hard to beat it. I use it myself largely with the best results, and the method has the merit also of being an expeditious one. Of course, it is not a desirable method on wet soils, but those are just the soils in which Potatoes should not be grown; indeed, it is fair to say that if the soil be too wet for dibbling over, it is unfit for Potatoes altogether. —A. D.

KITCHEN GARDEN NOTES.

WINTER'S WORK.—The sudden and unexpected advent of another winter—deep snow and as much as 16° of frost—has quite put a stop to planting, sowing, and cultivating; we can therefore furnish no notes of present doings, but will take a general survey of our winter's work, and how much more interesting would our gardening journals be if all who are capable (and there are few who are not) would but record their doings in certain departments at stated periods of the year. It ought to be our duty so to do, and thus conjointly would hints and ideas be gathered from the several records that would assuredly prove of great value to all, not to mention the satisfaction that one feels in having honestly striven to impart the best information in one's power for the use of the fraternity in general. Such, therefore, is the object of this note. Our special winter's work may be said to have begun with November, when most of the crops were exhausted or ready for harvesting; then is the most suitable time to make notes as to the following season's cropping in order that the various plots of ground may have the preparation, as regards manuring or non-manuring, digging, or trenching that is likely to best suit each particular crop. This, I need scarcely say, necessitates having a plan of the kitchen garden as a kind of working index to the diary of daily work, and having such a plan, the old one of the previous year is now brought into requisition in order that, in deciding the cropping of the following (*i. e.*, the present) year, the various plots may be occupied with crops of the most opposite description possible from those of the previous year. Strict rotation is not possible within the limited extent of our ground, and therefore we have quite given up attempting to follow that plan. We are satisfied if we can but arrange to grow Carrots, Beet, or Parsnips on ground that was last cropped with Celery, and so on throughout the entire garden. Well, all this we arranged in November, and with but slight modifications; contingent on unforeseen requirements it is a plan to which we shall doubt-

less be able to adhere. It just now occurs to me though that this exceptionally severe and long winter is likely to upset our arrangements considerably, as Broccoli is being slaughtered wholesale by this last frost. Kale and Brussels Sprouts, too, have suffered, and we must plant additional lots of Cauliflowers and Coleworts to make good such losses. The ground for these catch crops will probably be taken from that set apart for Potatoes, and the Broccoli and Kale ground be prepared for late crops of Potatoes instead of for Celery, as was intended, and Celery will then have to wait for the ground occupied by the earliest Cabbage. Apart from these unavoidable contingencies that in ordinary seasons are scarcely worth mentioning, this plan, or what I call a garden guide sheet, is of the utmost value, as it ensures the methodical, and therefore the most profitable, way of extracting from the soil the fullest amount of produce that can be got from it, because what one kind of crop does not utilise another will, or, in other words, what may be unsuitable for Peas will be relished by Potatoes.

The cropping decided, next comes the preparation of the ground, and here I may say that depth of tillage, for all and every variety of crop, I look upon as essentially necessary; therefore trenching is always preferred to mere digging, and practised when time allows. None of our ground ever goes more than two seasons without being trenched at least 3 feet deep; consequently we do not require to manure so heavily as must be done on shallow soils in order to keep the crops growing, and, what is more, tuberous-rooted crops always turn out of such ground straight and clean, which, if full of manure, would not be the case. As a matter of course, ground that is set apart for Peas, Brussels Sprouts, Runner Beans, Asparagus, Sea-kale, and autumn Cauliflowers is trenched deeply and highly manured. Then, as to manure, as we are not overdone with this commodity, we have to take into account our stock of all kinds, and use what we think most suitable for any given crop. For Turnips, Radishes, Spinach, and Lettuces we for the most part manufacture our own, by burning up all the refuse leaves, scraps of sticks, wood, and prunings that we can get together, the ashes from such a smother being equal to the best of manures for the afore-said crops. Soot and lime, a thin layer put immediately under the top spit and stable-yard manure at the bottom of the trench, are the best fertilisers for Onions, Shallots, and Garlic. Stable manure in its entirety is that which we prefer for all deep-rooting crops, such as Peas, Broccoli, Brussels Sprouts, and Kales. For Potatoes we are careful never to apply fresh manure of any kind; vegetable or leaf-soil, guano, bone-dust, Beeson's and several other kinds of artificial manures are preferable, as the tubers not only turn out cleaner, but in seasons when murrain has been prevalent I have noted immunity to some extent from that affection in the case of crops thus manured compared with those grown with fresh stable manure. We were in the midst of this work at Christmas when the great storm set in, and all hands had to be told off to cover up, with Bracken and long litter, Celery, Parsnips, Beet, Cauliflower plants, and herbs, and to lift sufficient supplies of Parsnips, Horseradish, Jerusalem Artichokes, and Celery to serve till the storm ended. Our next operations were cutting and pointing Pea sticks and Bean rods, and examining root and Potato stores to remove decay. This work ended—the snow had fortunately come before there had been any severe frost—by shovelling the snow and throwing it over the newly-trenched ground as each trench was completed, we were able to continue at that work till the storm was over, or rather till the snow had gone, for the frost still continued and prevented our completing the work; but the hard state of the walks and land was favourable for soil and manure-wheeling, and therefore mulching with long manure Raspberries, Strawberries, and narrow fruit-tree borders, as well as wheeling soil to places where it was needed for fruit-tree renovation and replanting, were done. Then came the end of the frost, followed by the finest February

weather on record, and trenching was all completed, seeds that it was desirable to sow were got in, and a commencement made at repairing Box edgings, turning and resurfacing with a bit of fresh gravel the walks, at which stage further progress is stayed by this new return of wintery weather. W. W.

TREES AND SHRUBS.

W. GOLDRING.

HELIANthemUMS AND CISTUSES.

I QUITE agree with all "W. G." says respecting the beauty of *Helianthemum (Cistus) algarvensis*, and also with his remarks as to the positions in which plants of this kind should be grown. The best example of *H. algarvensis* which I remember to have seen was in the midland counties, near Derby; it was growing at the base of a wall with a southern aspect; it was about 6 feet high and about 1 foot across. There are one or two other species equally beautiful with which I have met during my rambles in South Europe. *Helianthemum alyssoides* and *scabrosum* are two very similar plants, so much so, that even M. Gillet, in "Flore Française," omits to mention the latter. *H. alyssoides* is a twiggy, much-branched shrub, the branches of which are set at nearly right angles with the stem; the leaves are grey-green, small, and nearly round; the blossoms are as round as a wheel, and brilliant yellow in colour without spots. *H. scabrosum* has larger leaves, the branches are more upright, and the flowers, while similar in colour, are a little larger than those of *H. alyssoides*; in fact, the whole plant is more robust. The two are found growing side by side scattered in patches over a considerable area of country, generally on the outskirts of Pine forests. Bushes of them upwards of a yard high and as much through are when in flower a perfect blaze of colour. Large masses of them in full beauty are sights not easily to be forgotten. Although these two species come from so far south they have proved to be quite hardy, even at York; exposed on rockwork in Messrs. Backhouse's nurseries there, they have withstood without injury from 20° to 30° of frost. *H. umbellatum* is another interesting plant. In its wild station tufts of it may be seen fully a yard in diameter and about 12 inches high. It has small, narrow, Rosemary-like leaves, green above and somewhat silvery beneath. The flowers, which are borne in loose umbels, are pure white, and vary in size from a shilling to a florin. This plant is found abundantly in Central France and on the Eastern Pyrenees in exposed positions. *Cistus lavandulifolius* is another beautiful, upright, much-branched little seaside shrub, with narrow silvery leaves and soft, delicate, pale yellow flowers. This and *H. umbellatum* appear to enjoy a little peat and sand in the soil, which should also be well drained. *H. gattatum* is an annual species, the stems of which are erect, slightly branched, and from 6 inches to 12 inches high. The flowers, which are borne several together, are terminal, and as large as those of *H. (Cistus) formosum*, bright yellow, and with a handsome purple blotch at base of each petal. I have brought this home on several occasions, but have failed to cultivate it after the first year. It would be interesting to know if anyone has succeeded with it. R. POTTER.

The Constantinople Nut.—I have read with interest the account of *Corylus Colurna* (the Constantinople Nut), especially as I had in my kitchen garden here a very fine specimen of it, which I cut down in 1877, and then made the following memorandum concerning it: "Nov. 27, 1877. Just cut down a *Corylus Colurna*, a real curiosity; it was in the kitchen garden and took up so much room, that I was obliged at last to take it down, especially as the nuts were useless; they were so hard, that it was next to impossible to break them. This was really a tree, not a shrub in growth. The stem measured 6 feet in circumference at 2 feet from the ground, and 5 feet at 8 feet from the ground; it was straight up to that

height, when it branched. The ground shaded by the branches was 39 feet across." This tree I should think had been planted fifty five or sixty years before it was cut down. The figure of the nut (p 260) with its fringed beard is excellent.—W. WICKHAM, *Binned-H'gh, Alton, Hants.*

The Golden Cassinia.—I was in a nursery the other day where no tree or shrub is grown unless it be thoroughly hardy, and there I saw a quantity of this Australian shrub growing. It may therefore be regarded as hardy beyond a doubt, and no one need hesitate to plant such a pretty little Evergreen, which is so different from any other shrub hardy in this country. It is a low-growing and very branching bush, covered with tiny leaves, which are powdered on their under-surfaces with gold, as are the Gold Ferns, so that the bush has quite a golden hue at all seasons. The flowers are very small, but produced in long clusters terminating the shoots. It grows well in all kinds of soil, but thrives best in a light, sandy loam, in a dryish, warm spot. It has not been much planted, but, like other Australian shrubs, such as *Olearia Haasti*, which has also proved perfectly hardy here, it will become popular. *Cassinia fulvida*, the name of this golden shrub, is better known under its synonym, *Diplopappus chrysophyllus*.

Cupressus Lawsoniana intertexta.—Of the numerous varieties of Lawson's Cypress, that called *intertexta* is, in the opinion of many, one of the most beautiful and most elegant. It seems, however, to be too informal for some nurserymen, who dislike a tree, especially a Conifer, if it is less symmetrical than a sugar-loaf, or has any tendency to depart from the conventional Cypress growth. But such is the growth of *intertexta*; it takes a form different from any of its relatives; it spreads at the base and throws out its branches more horizontally than others, and these hang in a loose and most graceful way. The growth is never so dense as in an ordinary Lawson Cypress, and the whole plant is of a lighter shade of green on account of the branchlets being more glaucous. It is a pity that it is not a stock plant in tree nurseries, for one would like to plant it, as it is capable of producing a better effect in a group or isolated than most others. Messrs. Veitch catalogue it as synonymous with *juniperina*, but what Juniper it resembles in growth is not clear. The price that is asked for it is not in the least too high in comparison with that of other and, in our opinion, less valuable varieties.

A good climbing shrub.—*Ercilla spicata* is a name one may find in some nursery catalogues of shrubs, but the plant itself is but imperfectly known, though it is not without value as a climber; indeed, there is not a shrub that clings more tenaciously to a wall than this Peruvian plant. It has an abundance of thong-like branches, and when these are placed against a wall or tree trunk they send out myriads of stem-roots like the Ivy, and by these the plant fastens itself so strongly, that when it has made a huge overhanging head, the heaviest snowstorm will not dislodge it. A climber such as this is often needed in certain circumstances, such as a wind-exposed part of a house. It does not possess remarkable beauty of foliage or flowers, the former being small and pale green, while the latter are small and inconspicuous. The leaves are leathery in texture, and though normally evergreen, the plant loses its leaves in our winters as a rule. Besides its use as a wall covering, it is a capital plant for planting at the foot of a short tree trunk, pillar, or similar support. Its branches quickly reach the top of its support, and then spread out into a large umbrageous head as Ivy does, when it assumes its tree-like growth, but while the *Ercilla* is very rapid the other is comparatively slow. It is a native of Chili, whence it was introduced to Europe about fifty years ago, and has always proved itself perfectly hardy, even when planted against isolated stumps or pillars. It is known also under the name of *Bridgesia spicata*, and is catalogued as such by some nurserymen.

Bambusa Metake.—This Bamboo, when planted in masses of three or four together close to the edge of ornamental water, has a fine effect reflected on the water; indeed, such a position seems to suit it best, as it enjoys an abundance of water, especially during

the summer months, and a light rich soil that is free from chalk. The latter gives the foliage a sickly light green colour. This Bamboo is easily increased by dividing the roots, but it is not safe to plant it in positions exposed to much east wind. We lately planted a good specimen of it on the Grass, thinking it would look well in such a position, but the late severe frosts, combined with cold cutting east winds, have, if not killed it, quite spoiled the leaves by converting them to an ashy grey. When new growth takes place this defect will be somewhat remedied, but the plant will be disfigured for a long time. Do not, therefore, plant this charming Bamboo in exposed places if shelter elsewhere can be given to it.—SOUTH HANTS.

THE DOUGLAS SPRUCE.

(*ABIES DOUGLASSI*.)

OF late years there has probably been more written about the Douglas Spruce than about any other Conifer, both as regards its qualities as

of Larch, Scotch, and even Spruce, neglecting such trees as the Corsican Pine and the Douglas Spruce. The comparative scarcity and high prices of these two trees in the nursery have, of course, influenced planters; yet by this time, seeing that the tree has been introduced sixty years, plantations of it ought not to be a rare sight. Another point, no doubt, that has influenced planters is that the tree, though thoroughly hardy, will not succeed in exposed places where the sturdy Scotch, the Corsican, and other Pines are thoroughly at home. The Douglas must have shelter and a good soil, but there are thousands of acres in sheltered valleys in this country still under wood that would exactly suit the Douglas. Its growth is rapid when once it has become established, and surpasses even the Spruce in that respect, particularly in sheltered places along the southern coast line, where its annual growth varies from 2 feet to 3 feet. Some

The Douglas Spruce (*Abies Douglasi*); coning branch, flower, full-sized cone, cone-scale, seed and leaves.

a timber tree and its value for ornamental planting. Writers are all agreed that this tree has great merit for forest planting, and some even look upon it as the best substitute for the Larch should that tree continue to degenerate, as many assert it does. When such authorities on tree-planting as Sir Herbert Maxwell speak in unqualified praise of the Douglas Spruce as a timber tree for this country, no one need hesitate to make plantations of it. The home-grown timber has proved in all respects excellent, scarcely inferior to the imported logs of it, and by actual experiment it has been ascertained that it is stronger and tougher even than the Pitch Pine. But no one has had much experience of English Douglas Spruce timber grown in plantations, as there are very few places where it has been extensively planted, and this fact shows how hard it seems to deviate from the beaten track among planters. They still plant their acres

of the greatest annual growths I have seen are made in an avenue a mile in length at Bayham, in Kent. Throughout the course of the avenue the ground undulates a good deal, and the road and the trees follow the surface of hill and dale. On the high spots the trees are continually lashed by the wind, and therefore are miserable specimens—stunted and thin; but where the ground dips so that the avenue trees are sheltered from the wind, they shoot up long annual growths, and, moreover, are densely whorled with branches.

The trees in this avenue afford a good illustration as to the influence of shelter and exposure on the Douglas Fir, and one would hardly credit the fact that all the trees were of the same size and age at the time of planting, so great is the difference between those on the high ground and those in the low spots. The good soil which gathers in the low places may, of course, contri-

bute to the growth of the trees, but without the shelter they could not have made such rapid progress. Shelter, therefore, is essential for the Douglas Spruce, whether it be planted in masses or as isolated specimens, and coupled with this it should have a deep loamy soil to grow in in a moist, but by no means waterlogged, spot. The finest trees of *Abies Douglasi* I have seen in this country have mostly been in sheltered spots, protected from prevailing winds either by plantations, high ground, or buildings, and invariably on good, deep, moist soils. On thin, poor soils, and especially if exposed, it is almost always a failure. It succeeds on sandy soils, and particularly if it be peaty, and I have seen excellent specimens on the chalk; but, as a rule, it is not a good tree for such soils.

It is a beautiful tree in all phases of its existence, from the seedling stage to towering trees a hundred feet or more in height, and there are few more beautiful sights in a nursery than a mass numbering thousands of young plants just when they are bursting into new growth, and there is certainly no ornamental tree that presents such a noble and yet elegant aspect as a Douglas Fir when of such a size as that at Dropmore. This Dropmore tree is probably the finest in Europe, being now some 120 feet high, with a spread of branches of over 70 feet, and a girth of trunk at a yard from the ground of over 10 feet. It is truly a grand specimen, having a towering hole as straight as a mast, and regular whorls of feathery foliage from the top to the very base, where they sweep the turf. It was planted in 1828, and is therefore one of the oldest trees in this country, as it was only two years before that date discovered by the traveller David Douglas, who was at that time collecting for the Horticultural Society of London. It was from this source that Lord Grenville, the owner of Dropmore, obtained his seeds. From that time to this the tree has been largely planted throughout the length and breadth of these islands as an ornamental tree, and it is not too much to predict that it will be one of the trees of the future, and will be almost as important in an English park or garden landscape as the Lebanon Cedar. As to its value as a timber tree, that subject may be left for discussion in *Woods and Forests*, but few will question its importance from an ornamental point of view.

Up to the present there have been very few varieties crop up, notwithstanding the millions of seedlings that have been raised. There is a pendulous variety which is an even more graceful tree than the type, and a variety named *Standishi* having longer and greener leaves, and is similar to the variety *taxifolia*, which name is often applied to *A. Douglasi* itself, especially in old collections, on account of the tree having once borne the name *Pinus taxifolia*. A variety named *Stairi*, which has a sickly look, being neither golden nor silvery, is scarcely worth mentioning. Of the typical Douglas Fir there are evidently two distinct forms in nurseries—one having pale green foliage, while the other is very glaucous. The latter is said to be the genuine form, producing the best timber, and altogether a finer tree.

It need scarcely be mentioned that the Douglas Fir is a native of North America, where it forms boundless forests in the regions of the great far west, and extending as far south as Mexico. It was first discovered about the year 1797 by Menzies, but it was not till thirty years after that Douglas introduced it to Europe. According to the latest revision of the *Coniferae* this tree is strictly not a true *Abies*, but forms a genus by itself named *Pseudo-tsuga*, but it will

probably be a long time before this name is generally adopted. W. G.

SOCIETIES.

ROYAL HORTICULTURAL.

MARCH 22.

THE meeting of the fruit and floral committees was on this occasion held in the conservatory, and was very interesting, owing to the fine collections of plants and cut flowers sent by nurserymen, especially worthy of note being the groups of Hyacinths from Messrs. James Veitch and Sons and Messrs. Cutbush and Son, and the beautiful pot Roses of Messrs. Paul and Son, as well as the showy collection of Cyclamens from the St. George's Nursery Co.

First-class certificates were awarded to the following plants, viz., *Rhododendron balsaminiflorum carneum*, a double-flowered variety, the flowers of a beautiful saffron-yellow, shaded rose and as large almost as those of a *Gardenia*; shown by Messrs. Veitch. *Boronia heterophylla*.—A great acquisition to this beautiful class of plants, more especially as the colour, which is of a beautiful rose-crimson, is so effective; the flowers are very large, and borne in great profusion all along the stem, even in very small plants; in addition it is also sweet-scented; exhibited by Messrs. Veitch. *Zygopetalum Veitchi*.—This, the result of a cross between *Zygopetalum crinitum* and *Colax jugosus*, was carrying two flowers; the lip is beautifully spotted with rich violet on a whitish ground, the petals brownish, dashed with yellow; shown by Messrs. Veitch. *Hyacinth La Belle*.—A variety bearing a large spike of single flowers, which are of a beautiful pinkish colour; also exhibited by the Messrs. Veitch. *Odontoglossum triumphans* (Rosefield variety).—This plant was carrying two large spikes of fine large flowers; the petals and sepals of a dark chocolate colour, banded and tipped with yellow; the lip, whitish, with violet markings, and margined with yellow, very pretty; shown by Mr. De B. Crawshay.

In addition to the above certificated plants, Messrs. Veitch sent five new *Amaryllids*, viz., *The Bride*, white, striped with red; *Paulina*, the petals of a beautiful orange scarlet, having along the centre of each a distinct band of greenish white; *Hon. and Rev. J. T. Boscawen*, large and of fine form, scarlet, with distinct white band along the middle of each petal; *Hilarions*, a beautiful self-coloured scarlet; *Her Majesty*, white, blotched with red.

Messrs. Veitch also staged a very fine group of Hyacinths, the colours well arranged and displayed to advantage. Noticeable among the varieties were *Lord Derby*, porcelain-blue; *King of the Blues*, dark blue; *Lady Derby*, pure white, with fine large pips; *La Grandesse*, very fine white; *The Sultan*, dark blue, and many others. A silver-gilt Banksian medal was deservedly awarded.

Messrs. W. Cutbush and Son, The Nurseries, Highgate, staged a somewhat similar group to the above, the flower-spikes and individual flowers being large and good. Worthy of note were *Madame Van der Hoop*, large single white; *Linneus*, single red; *Pondin*, similar to *Lord Derby*. A silver Banksian medal was awarded.

Messrs. Paul and Son, The Old Nurseries, Chess-hunt, staged a beautiful group of pot Roses. These were remarkably fine for the season. Conspicuous among them were *Lady Mary Fitzwilliam*, of a light pink colour, large and full; *Innocente Pirola* as a half standard, bearing very large creamy white flowers; *Dr. Andry*, beautiful scarlet; *Francesca Kruger*, saffron-yellow; *Jean Ducher*, very distinct and pretty; *Rubens*, large and fine; *Heinrich Schulteis*, large, bright pink. In good condition also were the *Polyantha* varieties *Mignonette*, pink, and *Paquerette*, white; the curious *Rosa viridiflora* and *Rosa rugosa alba*. A silver Banksian medal was awarded.

Messrs. Paul and Son also exhibited the two *Saxifrages* *Frederici Augusti* and *Sancta*, the former of which has longer flower-spikes and paler yellow flowers. The same firm also sent a beautiful white Lilac,

named *Marie Lemoine*; the flowers and trusses were large and freely produced.

Mr. Drost, Kew Nursery, Richmond, contributed a very fine lot of *Spiraeas* and *Lily of the Valley*. These arranged on the ground in a circular form were very much admired. A bronze Banksian medal was awarded. Mr. Drost also exhibited a new Tulip and some cut sprays of English-grown Lilac, which were remarkably good.

Mr. George Maw sent a dwarfed Japanese *Pinus*, said to be thirty years old.

Mr. De B. Crawshay, Rosefield, Sevenoaks, sent five varieties of *Odontoglossum*, including the one alluded to above. Mr. Todman, Rose Park Nurseries, Upper Tooting, exhibited nine varieties of *Azaleas* of the hybrid Chinese type. Mr. Palmer, gardener to Mr. J. H. Powell, sent cut blooms of *Odontoglossum excellens* and *Pescatorei*. Mr. Gilbert, Bourne, Lincolnshire, exhibited a bright yellow Primrose. Mr. G. F. Wilson, Heatherbank, Weybridge, sent the *Trencham* variety of *Coleogyne cristata*. It was growing in a small pot, and bearing a fine spike of flowers. Mr. Wilson also contributed some fine hybrid Christmas Roses. Mr. Charles Turner, Royal Nurseries, Slough, sent a beautiful lot of the new *Violet Wellsiana*. These were covered with bloom. The flowers are of large size and of an intense blue. Mr. H. A. Mangles exhibited a plant of the handsome *Sikkim Rhododendron Falconeri*, carrying a truss of large, creamy white flowers. Mr. F. A. Philbrick, Bickley, exhibited *Cypripedium Bartetti*, a cross between *barlatum* and *Chantini*. The flower is of a dark copper colour, petals and sepals of the same shade, the dorsal sepal large, margined with white and splashed with violet, the centre striped with dark brown streaks. Mr. Philbrick also showed an *Angraecum citratum* bearing two large spikes, each about 2 feet long, of its beautiful ivory white flowers.

Mr. T. S. Ware, Tottenham, staged a very representative collection of *Narcissi*, intermixed with *Anemone fulgens*, *Chionodoxa Lucilia*, Tulips, *Anemone coronaria*, very fine; *Doronicum Clusii*, bright yellow; *Megasea speciosa*, and a few Tree Peonies. A silver Banksian medal was awarded.

Messrs. Barr and Son exhibited a very fine collection of *Narcissi*, interspersed with the beautiful *Cocos Weddelliana*, rendering the group very effective. Included in this group were *Anemone fulgens*, *Anemone coronaria*, *Iris reticulata*, &c. A silver-gilt Banksian medal was awarded. Messrs. Barr and Son also staged a collection of hybrid Christmas Roses.

Messrs. Collins Brothers and Gabriel exhibited a collection of *Narcissi*, and a handsome gathering of *Chionodoxa Lucilia*, which was very effective. Prominent in this group were *Anemone fulgens* and *Allium album*. A silver Banksian medal was awarded.

The St. George's Nursery Company (Mr. H. B. Smith, manager) staged a fine group of Cyclamens, very noticeable being the white varieties, which were of large size. Other colours too were good. A silver Banksian medal was worthily awarded. Messrs. Green and Nephew exhibited their *Munstead* flower-glasses.

Fruit committee.—Mr. S. Ford, the Gardens, Leonardslee, Horsham, sent a collection of fourteen varieties of Apples, the best being *Norfolk Beauty*, *French Crab*, *Mère de Ménage*, *Golden Reinette*, *Duck's-bill*, *Yorkshire Greening*, *Adam's Parnain*, and *Miss Margaret*, a small, late, very highly coloured Apple, which the committee considered very promising. Mr. Ford also sent a dish of *Uvelale's* *St. Germain Pear*. A cultural commendation was awarded for the collection.

Mr. G. Allis, Old Warden Park Gardens, Biggleswade, sent sixteen dishes of Apples, noticeable as being in good condition were *Norfolk Beauty*, *Wellington*, *Striped Beauty*, *Blenheim Orange*, *New Hawthorn*, and *Northern Greening*. The whole collection had been well kept. He also staged three bunches of *Black Alicante Grapes*, for which a cultural commendation was awarded.

Mr. Roupell exhibited eight dishes of Apples, *New Northern Greening*, *Wellington*, *The London*,

or Five Crowned Pippin, Lane's Prince Albert, and Beauty of Kent being the best.

Mr. J. Barnett, Decker's Hill, Shifnal, sent a seedling Apple, of which the committee required a larger number to be shown.

The Gardeners' Orphanage.

A meeting of those interested in establishing the above was held in the conservatory on Tuesday, the 22nd inst., when the following resolutions were proposed and unanimously carried:—

1. That, in the opinion of this meeting, it is desirable to establish a fund to be called "The Gardeners' Orphan Fund."

2. That a provisional committee be appointed to prepare a scheme and lay it before a future meeting, and that the said committee consist of the following gentlemen: Dr. Masters, S. Hibberd, G. Deal, J. Wright, J. Roberts, C. Penny, B. S. Williams, W. Richards, J. Douglas, J. Fraser, C. H. Sharman, H. J. Veitch, J. Woodbridge, A. F. Barron, R. Dean, and John Matthews.

3. That W. Richards be appointed treasurer of the fund.

4. That the following gentlemen, viz., A. F. Barron, J. Wright, B. Wynne, be appointed honorary secretaries.

Narcissus committee.—The first meeting this season of the Narcissus committee was held at South Kensington on Tuesday last when the chief objects of interest submitted were very good specimens of flowers from roots collected at various times from their native habitats chiefly in Spain and Portugal, including many forms of pseudo-Narcissus, triandrus, Corbularia, and natural hybrids. Many of these had been sent home by Mr. George Maw, who also brought some of his own collecting and described the situations in which they were found growing. An interesting communication was made by Mr. Threlfall on the rudimentary forms of some organs found in certain varieties, by the presence or absence of which he hoped that it might be possible to distinguish in some cases one species from another, and which might prove of assistance in bearing on the question of doubtful hybrids; but as he was still at work on the subject he promised a further communication later on. Some fine flowers were sent from Ireland, but owing to the severe weather almost all the English ones had been opened under glass, and so could not be reported on. It was determined to hold a meeting on May 10 as well as the two in April (12 and 26) already advertised.—C. R. SCRASE-DICKINS, *Hon. Sec.*

ROYAL BOTANIC.

MARCH 23.

THE first spring show of the season held by the above society on Wednesday last was rendered very attractive by the magnificent display of spring-flowering plants, notably Hyacinths, Narcissi, Cyclamen and Camellias. It is very much to be regretted that there are no prizes provided for Orchids, which are now at their best. These might well be encouraged, seeing that there is such a wealth of bloom in most of the collections around London. Azaleas were very poorly represented.

Independent of the plants staged in competition for the prizes, miscellaneous groups helped to make the exhibition very attractive. In the competition for hardy herbaceous plants Mr. Douglas took first and only honours with a beautiful lot, comprising among others good plants of Solomon's Seal, Fritillaria Meleagris and its white variety, Megasea Strachey, and the lovely *Sisyrinchium grandiflorum*. In the hardy Primula class Mr. Douglas was also to the front with *P. rosea*, *nivea*, *obconica*, very fine, *intermedia*, &c. Messrs. Williams and Son staged a very handsome lot of Lily of the Valley. Messrs. Paul and Son won first honours with Roses in pots, and in the Amaryllis class Mr. Douglas showed some excellent varieties, including Dr. Masters, Calypso, John Heal, and one of his own raising, which was also certificated. The Cyclamens from Mr. J. Odell were beautiful plants, one mass of bloom, the white varieties especially good.

Messrs. Jas. Veitch and Sons, Chelsea, staged a fine group of Hyacinths, which were worthy of the large bronze medal awarded them. They also exhibited several new Amaryllids, and the new and beautiful *Boronia heterophylla*, as also other new plants.

Messrs. W. Cutbush and Sons, Highgate, in addition to the group of Hyacinths which they staged at Kensington last Tuesday, on this occasion added an effective display of Tulips. A small silver medal was awarded.

Messrs. Wm. Paul and Son, Waltham Cross, staged twelve very large plants of Camellias, as also some smaller ones, very noteworthy being one named Cup of Beauty, a white variety very much suffused with pink; Mr. D. Offey, white; C. M. Hovey, bright scarlet; Belle Jeannette, red with white markings. In addition to the above they also staged twelve boxes of cut blooms and well-flowered plants of Clematis *indivisa lobata*. A silver medal was awarded for the collection.

Messrs. Paul and Son exhibited a group of Tea and other Roses, including Mignonette and Paquerette of the Polyantha class; the curious *viridiflora*, and a white Lilac named Marie Lemoine, as also a small group of rock plants. A large bronze medal was awarded.

Mr. W. Rumsey was awarded a large bronze medal for a group of Roses, very fresh and pretty.

Mr. B. S. Williams, Upper Holloway, sent a very fine lot of Hyacinths, Tulips, Narcissus *Tazetta*, Cyclamen, and varieties of *Imantophyllum* minutum, forming a very attractive bank. The *Imantophyllum*s were carrying large heads of intense orange-scarlet blooms and were very effective. A large silver medal was awarded.

Messrs. Williams and Sons, Fortis Green, Finchley, in addition to the plants they had put up for competition, exhibited a group of Hyacinths. They were well grown, the foliage and flower-spikes stout and dwarf. A large bronze medal was awarded. Messrs. Williams also staged a group of spring-flowering plants, consisting of Narcissi, early flowering Pelargoniums, *Cytisus*, Azaleas, Lily of the Valley, &c., all well grown. A silver medal was awarded.

Mr. H. R. Wright, Turner Road, Lee, exhibited a fine group of Hyacinths. A large bronze medal was awarded.

Mr. James, Woodside, Farnham Royal, sent a large group of his now well-known Cinerarias, perfect in form, and having very showy colours. A large bronze medal was awarded.

The St. George's Nursery Co. (H. B. Smith, manager) received a bronze medal for a collection of Cyclamen, the flowers varying from pure white to dark purple.

Mr. J. Odell, Gould's Green, Hillingdon, exhibited a group of Cyclamens, the dark colours in this collection being exceptionally good. A large bronze medal was awarded.

Mr. Henry Little, The Barons, sent a very attractive group of varieties of *Lycaste Skinneri*, ranging very much in their shades of colour and markings, one named *gloriosum* being very noteworthy. In this group were also some cut spikes of *Odontoglossum* and *Cattleyas*, very fine. A bronze medal was awarded.

Mr. F. C. Jacob, Stamford Hill, sent a collection of *Odontoglossum*s, consisting principally of *O. crispum*. These were intermixed with *Adiantum*s, giving them a pleasing appearance. A bronze medal was awarded.

Mr. Charles Turner, Royal Nurseries, Slough, contributed a small group of Violet *Wellsiana*. Messrs. Barr and Son, Covent Garden, were awarded a large bronze medal for a group of Narcissi and other spring-flowering plants. Messrs. Collins Brothers and Gabriel put up a group of Narcissi, and were awarded a bronze medal. Mr. Drost, Kew Nursery, Richmond, staged a very attractive group of *Spiraeas* and Lilies of the Valley, with cut spikes of Lilac (English grown). Mr. T. S. Ware contributed a good display of Narcissi, &c., and Mr. J. Wiggins, gardener to Mr. W. Clay, Grove Road, Kingston, sent a group of Cyclamens.

Mr. W. Gordon, Duke Street, St. James's, sent a bouquet composed of *Cattleya Trianae* and Lily of the Valley; and MM. Francoise et Cie, 104, Regent Street, sent a basket of Roses and white Lilac, and

also a harp composed of Forget-me-not, Lily of the Valley, and white Lilac.

Messrs. Cheal and Sons, Crawley, Sussex, sent forty dishes of Apples. These had been well kept, and were very good examples.

Botanical certificates were awarded to the following, viz.: *Boronia heterophylla*, exhibited by Messrs. Veitch; *Selaginella gracilis*, a slender, arched form after the manner of *Wallichii*, also exhibited by Messrs. Veitch.

First-class certificates were awarded to Amaryllis *Her Majesty*, a white flower of good form; *Titania*, red, with white centre; and Hon. and Rev. J. T. Boscawen, white, splashed and dotted with scarlet. These were all shown by Messrs. Veitch. *Rhododendron balsaminiflorum carneum*, a double-flowered variety with flowers of a beautiful saffron-yellow, shaded rose. Exhibited by Messrs. Veitch. *Cineraria Blue Bonnet*, large flower, blue edges, with white centre; *Meteor*, a dark blue self; *Illuminator*, dark purple; *Stella*, dark maroon. All these shown by Mr. James. *Amaryllis Oriflamme*, flowers large, of fine form, rich scarlet, with distinct band reaching half way along each petal. From Mr. Jas. Douglas. *Cyclamen Royal Jubilee*, a very dwarf and compact variety, the flowers large, intense crimson; certainly the darkest coloured variety yet raised. Exhibited by Mr. Odell. *Oncidium Brunleesianum*, a variety with small flowers; the petals and sepals pale yellow, with dark bands across them; the lip bright yellow, with dark brown blotch on middle lobe. Exhibited by Mr. R. B. Lemon.

A detailed prize list will be found in our advertising columns

LAW.

PURSER V. THE WORTHING DISTRICT LOCAL BOARD.

THIS was a matter relating to rating. Mr. Purser was a grower of fruit, vegetables, and flowers at Worthing, where he had one acre one rood of land, on which were sixteen glasshouses, which covered almost all the land. He called himself a market gardener and nurseryman, and he grew for the market Tomatoes, Cucumbers, and other vegetables, and also Grapes and flowers. The statute said that "market gardens and nursery grounds" should be rated at only one-fourth, and the question was whether the appellant's property came within this exception. It was argued that the property in question was a market garden. All the plants were grown from the ground, and sometimes the roots were in the open ground. It was a garden covered with glass. For the District Board, it was submitted that this was in no sense a market garden. What was carried on really was a new industry, and it was desirable to have the decision of their Lordships, because in some places such land was rated in full and in other places it was at one-fourth under the exception. So far from the place being an ordinary market garden, the things were grown there by means of heat, water, and soil all supplied artificially. Mr. Justice Day said that in his judgment this place was a market garden. He failed to see how a garden was the less a garden because it was protected by high walls or a glass roof. Judgment for the appellant, with costs.

Names of plants.—*A. C. (Dumfries)*—A handsome variety of *Odontoglossum triumphans*—*C. J. (Dover)*.—*Cypripedium insigne punctatum violaceum*; Fern: 1, *Urtica trapeziformis*.—*New Holland*.—1, *Eriostemon cuspidatum*; 2, *E. scabrum*; 3, *Acacia leprosa*.—*J. C. R.*—A fine variety of *Imantophyllum minutum*.—*Anatole (Newcomb)*.—1, *Odontoglossum Alexandre*, a poor starchy flower; 2, *O. Pescatorei*; 3, *O. pardinum*.—*W. S. B., Dundee*.—1, *Phlebodium aureum*; 2, *Doodia aspera*; 3, *Pellaea hastata*; 4, *Asplenium lucidum*.—*J. H. McK., Manchester*.—*Acacia pulchella*.—*W. Bartholomew*.—*Vaccinium serpens*.—*W. W., Epsom*.—1, *Sparmannia africana*.

WOODS & FORESTS.

"YORKSHIREMAN."

THINNING PLANTATIONS.

My attention has lately been drawn to Lindley's remarks on this subject, and which are apparently opposed to what some of your correspondents, including myself, have advocated. The passage had escaped me, and as it evidently lends support to those who advocate severe thinning, the branch growers, as I call them, and has no doubt influenced planters hitherto, it may be usefully quoted and examined here. I have much respect for Lindley's opinions as a rule, but in some practical matters he was mistaken, and that this was the case in his views on thinning plantations for timber, while his physiology was right enough, I think, can be easily shown. Lindley refers to an actual example of a Spruce Fir from a North Yorkshire estate "in which reliance had been placed upon crowding as a substitute for careful tending" (exactly what we advocate within safe limits), which showed that the annual deposit of tissue on the trunk—that is, the timber layers—decreased steadily and in proportion as the trees grew up and got more crowded, the first five years putting on 26 10ths of an inch, and in the last few years not above a quarter of that bulk. "In thirty-five years the tree only acquired a diameter of 10½ inches;" "whereas," he adds, "had the tree been properly treated, it ought, by the end of thirty-five years, to have been 18 inches in diameter;" that is to say, if it had had room to grow branches down to the bottom that would have been the result" ("Theory and Practice of Horticulture," pp. 410 and 411).

From these facts Lindley concludes that in thinning for timber it is better,

as a general rule, that no one tree should be permitted to touch another. Practically it is impossible to adjust the thinning of a plantation with such exactness, and in the annual removal of such trees as are touching others, spaces larger than are actually requisite, according to this rule, will be found. This, however, is an advantage, because it allows the wind to find its way easily among trees, &c.

Such is the advice of one of the best and soundest authorities on vegetable physiology, and it entirely supports the views of the severe thinners whom we have so often condemned. Yet Lindley's arguments, though sound physiologically, have not a leg to stand upon when it comes to the question of growing timber for its value—the final and all-important consideration. It is admitted that there is no surer way to grow to a single thick tree trunk in the least time than by giving it room to produce as many leaves and branches as possible, but—and there is everything in this but—that is not the way to grow the greatest quantity of the best timber to the acre. Where Lindley's big Spruce could be grown, probably half a dozen of smaller dimensions, but more bulky in the aggregate than the big one, clean, straight, and free from knots, could be grown that any timber merchant would jump at, while the rough big Spruce would hardly pay for its removal from the ground, and this applies to all trees less or more. Had Lindley only carried his arguments to the timber yard, I have no doubt he would have acknowledged his error.

THE RIGHT MEAN.—The practical question for foresters to settle is the right degree of thinning necessary to ensure the greatest quantity of saleable timber to the acre, and that is just the question that hardly any two foresters are agreed about, and which has never been solved because of the wretched mixed system of planting generally followed by which Firs and deciduous trees of all rates of growth and of different habits have been put in pell-mell together. Anyone, however, who can measure timber and has access to plantations may soon satisfy himself that trees thinned to the extent recommended by Lindley and his followers, or on his principle, produce the most timber individually, but the least quantity to the acre or to the square yard. We have measured old and favourite Larches that have always had room, and whose branches extend from 21 feet from

the base all round, where no other trees interfere, and we have measured others that have just half that room owing to their being crowded, the age and conditions of growth in each case being exactly the same otherwise, and find that while the confined tree has 50 feet of good timber in it, is branchless and clean for 40 feet up, the other has only 68 feet, and is very rough and knotty. A simple sum in arithmetic will show anyone the immense gain per acre the confined tree gives; and the same result holds good in all cases.

PROTECTION FOR THE TRUNKS OF TREES.—The trunk or stem of a tree may be likened to the backbone of an animal. It is the channel of communication between the root and the branches, and when any serious injury happens to it the whole tree is affected. In woods and plantations the importance of protecting the trunks of the trees is not often realised, and I fear that the decay noticeable in not a few Oak woods of mature age is due to causes affecting the trunks of the trees. When a tree is planted in an open space it clothes itself almost down to the ground with branches, especially the Fir, which branches shade the trunk in summer and protect it in winter. In a thick forest the trunk is not clothed in this way, but the branches of the trees form a canopy overhead and protect each other just as effectually, or even more so. In summer in such a wood the atmosphere is cool and moist below the branch line, evaporation being checked and the sun excluded, and in winter cold winds and frosts are excluded to such an extent, that when the ground in the open fields is hard frozen in the woods it is soft. But what happens in the case of a mature tree that has grown up under these conditions and then been thinned out in the usual way when a fall of timber is taken out? Simply this. The hitherto sheltered tree trunks are suddenly subjected to vicissitudes of cold, drought, and heat, such as they have never experienced before, and the effect or shock if we could realise it must be akin to that experienced by a human being who has suddenly been stripped of half or the whole of his clothing. I know certain extensive woods that the more they have been thinned the faster those left have decayed, and if it is not due to the exposure of the trunks, I am unable to assign a cause for their decline. In these woods, too, the number of ring-shaken trees is great, and every forester knows how seriously "shakes" reduce the value of timber, if they do not render it useless altogether except for firewood. The cause of "ring-shake" has never been satisfactorily explained, but the probability is that it is caused by frost or weather conditions of some kind. It cannot be supposed that a tree that has grown all its life in a crowd of others till it had made a trunk perhaps 40 feet in length destitute of branches could remain unaffected by exposure to the weather. But what has to be done when timber has to be removed from such woods? There is only one answer to the question, viz., do not thin out thick woods so severely as to admit the light and air to an injurious degree, but rather fell the timber in blocks and replant. Nurserymen say that it is not a good plan to plant trees from the nursery above 3 feet or 4 feet high, because they become hide-bound and do not grow so well as smaller trees do. Still, be this as it may, it is necessary under some circumstances to plant good-sized trees at the outset, and I have an impression that if they were always planted thick enough they would grow. It is their coming out of the crowded nursery lines to be planted may be on a wind-swept plain or hillside that stunts them for a time. When bark and stems are frozen in winter and parched in summer, and nothing else than a severe and lasting check can be expected, thick planting at the outset is the only safeguard.

— I am glad to see "Yorkshireman" (p. 267) referring to this matter. Few except theorists, I apprehend, go in for light and air. Everybody must know that there is always too much waste in the shape of knots and branches, however well a tree may be grown, and they must also know that everything which tends to

isolate growing trees also tends to an increase of branches. I do not, of course, wish to imply that it is impossible to crowd trees too much, but such a process of thinning as that sketched in THE GARDEN (p. 267) is most prejudicial if good timber is the aim of the grower. The "unbroken leaf canopy," which "Yorkshireman" quotes, is a reliable index to the forester, and anything short of a complete canopy is certain to lead to the development of lateral branches, and the timber value will be nil. This is not only true of the Pines, but also of our common English hard woods, notably so of the Beech: in fact, a thickly grown Beech wood will afford a better example of the way in which the best timber is produced than the Pine wood itself. I have had from time to time opportunities of visiting what are perhaps some of the finest Beech woods in the kingdom, and one is always struck with the circumstance that the tallest and cleanest boles are where the trees are growing thickly, or, to use Mr. Webster's words, where "the leaf canopy is unbroken." To see the effect of the light and air treatment, it is only necessary to repair to the margins of the wood or to isolated trees of the same kind. Hard pruners first of all thin to such an extent as to induce lateral growth, and then they are obliged to chop and hack away in order to destroy the growth which their bad judgment has encouraged. Such a plan militates against the production of good timber on a given area at the smallest cost. Left to grow on naturally, at least a third more trees would thrive on the same amount of land. These trees would be of infinitely better quality than those which have been deprived of their branches by artificial means, and finally all the cost of such pruning would be saved. In the face of such facts as these it is difficult to see what can be the motive of the advocates of pruning and thinning. One can only wish them the opportunity of disposing of their carefully manipulated produce side by side with the timber which, by a proper appreciation of natural conditions, has been allowed to thin and prune itself.—WILTS.

THE PYRENEAN PINE.

(PINUS PYRENAICA.)

IN my memory the above tree is always associated with an ungainly, tortuous-branched Pine—an error, no doubt, that got rather firmly implanted in my mind years ago by the daily sight of a clump of this very Pine, and that, perhaps, from accountable causes had anything but an ornamental appearance. The opposite of this is, however, the case, for the Pyrenean Pine is a highly ornamental tree, the beautiful light green leaves and conspicuous orange-tipped branches rendering it peculiarly distinct and interesting. Speaking truthfully, this is the case only in young and vigorous-growing specimens, for when old age is attained a much coarser habit of growth is partaken of, and the ungainly, tortuous-branched tree of my old remembrance is well represented. Rather more than half a century ago this Pine was introduced into England by Captain Cook, but that it has not taken extra well with tree planters is only too evident from its somewhat sparse distribution even at the present day, although this must not wholly be attributed to a general dislike to the tree by arboriculturists, but partly to the difficulty in procuring either seeds or seedlings and true to name. The stem of this Pine always puts me in mind of that of the Austrian or Corsican, while the branches, which are thick and strong, are regularly, although in most cases somewhat sparsely, arranged around the body of the tree. A bright green colour suffuses the leaves, more particularly in young specimens, these being variable in length as well as in arrangement, usually, however, 6 inches long and arranged in pairs. The cones are usually curved, about 3 inches long by fully an inch diameter at base, and arranged singly, but sometimes in twos. The bright orange-coloured bark of the shoots is very conspicuous and pretty, and renders recognition of this Pine easy indeed.

Rejoicing in no less than eleven different names, it is pretty evident that the Pyrenean Pine is confused with other nearly allied species, but by paying attention to the orange-tipped shoots recognition should be easy enough. We have seen specimens of this Pine that could hardly be distinguished from the *Laricio* save by the above-mentioned peculiarity, while others, again, resemble *austriaca* in a marked degree. It is readily enough raised from seeds by sowing these in boxes and placing them in a cool frame until they have attained a height of an inch or more, but this care is, perhaps, unnecessary, only that as seeds are difficult to procure one is reminded that a little extra attention is well bestowed if only for the sake of economy.

Good strong loam, rather dampish, suits well this Pyrenean Pine—at least, in such soil grows our finest specimen, and where it is partially sheltered by a clump of old and gnarled Oaks. We have seen it, however, thriving luxuriantly in peat soil on an Irish estate; indeed, about the largest and healthiest trees we have come across, as well as the largest in number, were growing in reclaimed peat bog, where flourished in all their grandeur as beautiful a collection of hybrid *Rhododendrons* as I have ever been privileged to behold.

A. D. WEBSTER.

CHOICE HOLLIES.

HAVING a fair collection of Hollies growing on the lime and old red sandstone, "W. G." (p. 267) is quite correct in surmising that the half dozen to which I draw attention do not exhaust my stock. Indeed, with the exception of *I. balearica*, which is capable of taking care of itself, I look upon the others as specialities which all lovers of this princely family should grow where climatic conditions suit them. Unfortunately, these do not pervade the whole of this island, but surely there are few places in which a sheltered nook or a few yards of wall cannot be found, and I question if *I. dipyrrena* and *I. latifolia* would not cause more inquiry than all the other Hollies put together. Before I proceed further I must pause to thank "W. G." for introducing *I. insignis* and *I. Fortunei latifolia* to my notice. I have not grown them, but upon the strength of his remarks shall certainly obtain plants in April. The first should be a worthy companion to *I. latifolia*, and a broad-leaved *I. crenata* will carry body which the normal form lacks. Slowness of growth is an advantage, as winter bedding gardeners are so frequently obliged to discard to the shrubbery *Retinosporas* and the hackneyed run of bedding Conifers generally. *I. Dahoon* does very well here, and a variety which I have been told is *I. opaca* is very handsome, but I am doubtful if it is true. It was planted before I came to Eastnor, and the late Mr. W. Osborne, the most careful namer of hardy trees I ever met with, was my authority. Hollies being so numerous and the type, *I. Aquifolium*, so good, varieties and species are not so extensively planted as they should be. Who would be without the handsome *I. Hodginsi*, *I. Shepherdii* or *nobilis*, the neat-growing *I. ovata*, or the bright spineless-leaved *I. laurifolia*? and would he extend his list to a score or more he might add *I. crassifolia*, *I. latispina*, *I. platyphylla*, *I. serratifolia*, *I. scotica*, *I. myrtifolia*, *I. Perado*, *I. balearica*, *I. altaclarensis*, and *I. flava*, a most beautiful shrub whose fruit the birds so kindly spare until they are hard pressed by hunger. Lovers of drooping Hollies may plant all the weepers, plain and variegated, worked, of course, on tall straight stems as lawn specimens. Of variegated forms the name is legion. The beautiful Golden Queen, of course, stands at the head of this list. Waterer's Golden is a best in itself and makes grand standards, pyramids, or round-headed bushes for those who can wait. The gold-margined, the silver-margined and the Milkmaids are gems of the first water, and may be duplicated to any extent. A gold-blotched variety recommended to me by the late Mr. J. Veitch is very handsome, but requires close attention when in free growth, otherwise it is apt to hark back to the bright, almost black, spineless

leaved *I. laurifolia*. Last, but not least deserving, the Hedgehogs, green, gold, and silver, should be well represented. They are quaint, and form handsome touch-me-not bushes, which must be seen and handled to be fully appreciated.

W. COLEMAN.

MAKING PARK ROADS.

ROADS and drives on private estates, and even on the highways, which are supposed to be managed by people who understand their business, afford plenty of examples of macadamising that would make the hair of the original inventor of the system stand on end were he alive. The real truth of the matter is that the majority of people who have to do with road-making only know the system by name, and have a vague idea that it simply means spreading plenty of stones on the ground and nothing more. Hence it is that so many roads are so uneven and always being repaired with no better result, and to the continual inconvenience of traffic and discomfort to pedestrians. Few people know how easily a good and properly macadamised road can be made, or understand how excellent and enduring such a road is. A man who thoroughly

UNDERSTANDS THE SYSTEM, and sees it carried out properly, will make a better road with a few inches of broken stones than others will make with three times the quantity of material, not to mention useless labour. Macadam cared very little what sort of a bottom he had to deal with if it were not an absolute morass, and he was not often deterred by that. "For a road," he says, "it is not necessary to lay a foundation of large stones, pavement, &c., as it is a matter of indifference whether the substratum be hard or soft, and, if any preference is due, it is to the latter." These statements look like heresy compared with much that we have read on road and walk-making, but the great road-maker was right, nevertheless. First of all, whatever the bottom was like, he took care to see that the ground had evenly settled before the stones were spread upon it, that there might be no subsidence in any part afterwards to cause inequalities, a matter which is often overlooked. When the roadway had to be cut and levelled, large stones dug out of the ground, or any inequalities to be made up, the ground was afterwards left to settle before proceeding further with the work. In putting on the stones quite as much care was exercised.

THE HARDEST STONE in the district was procured—granite, flint, or whinstone; next, it was broken to the regulation size—in pieces about an inch in diameter, though a rougher size will do; and, lastly, the stones were not laid on the road, but spread shovelful after shovelful to the depth of from 6 inches to 10 inches, which was considered sufficient for general highway traffic. The road was made slightly higher in the centre than at the sides to throw off the water, as the object was to form an impermeable crust that would keep the water from percolating to the bottom, thereby rendering it soft and causing it to work up, the necessary drainage being, of course, secured in the usual way. This is macadamising in the proper sense of the term, a system which has nearly superseded every other, but it is the attention to trifles in carrying it out that makes perfect work. For example, many people would attach little importance to the stones being broken or angular, and be quite as indifferent about the mode of spreading them on the road; yet these are two of the most important points. The use of water-worn stones of the same size will not make a solid crust, because they yield to pressure, their round surfaces offering little or no resistance; but it is different with broken stones, which when of uniform size, and clean, and properly spread on the ground, set fast on the same principle as that of an arch. I have seen roads made on an extensive scale on this system, and had to make such myself, and I have never seen anything to equal them.

WALKS, which are often cut out deep and filled in in the bottom with large stones, may be made on Macadam's principle with far less trouble and with much better results. Broken stones, to the depth of 2 inches or 3 inches, will be quite sufficient, and

they should, after being spread on, be beaten even on the surface with broad wooden rammers. This sets the crust effectually at the beginning. Afterwards a thin coating of clean gravel should be spread upon the surface to hide the stones, but no more. Such a walk is smooth and firm, and comfortable to the feet in all weathers; rain only washes it clean, and frost has not the least effect upon it if the bottom be drained. The material holds no moisture to freeze; it is the accumulation of soft gravel on the surface of walks that freezes and renders them so muddy and uncomfortable afterwards. With us the stones are broken by a machine to any size we want them.

J. S.

The Privets.—"Yorkshireman" (p. 267) does not say too much in favour of Privets for hedges and coverts. Both varieties named by him are used extensively here, but, like him, I find that the narrow-leaved variety makes the best covert, being more dense and spreading. As regards hedges, however, it is questionable which variety is best. The oval-leaved variety, though more erect than the common one, may, if regularly clipped, be kept dense and close right down to the ground, and here it is quite an Evergreen, or nearly so. At the present time it is quite green, whereas the leaves of the common sort are brown, and in many cases it is leafless. Both varieties thrive well on this cold east coast quite close to the sea.—OLITOR, *Northumberland*.

Furze for hedges.—In very cold localities, where other hedge plants will not thrive well, this makes a beautiful and useful fence—beautiful from its having such a profusion of bloom, and useful because it is cropped in winter by sheep, and the clippings eaten by cattle and horses. It is short-lived, however, and is subject to be killed down during severe winters. It is apt, also, to become bare and unsightly at the bottom. In forming a hedge of Furze, the plan pursued throughout most parts of England is as follows: A bank of earth is raised 5 feet wide at bottom, 3½ feet high, and 20 inches wide at top. In March a drill is drawn on the top along the middle of the bank, and the seeds sown therein and covered to the depth of 1 inch. In two years the plants will begin to grow luxuriantly, spreading downwards on each side over the bank, so as to almost cover the whole of its surface. This fence should be clipped once a year, between November and March, the particular time being regulated by the demand for the clippings as fodder.

Ilex crenata.—Mention is made in THE GARDEN (p. 246) of this pretty little Holly, and in the article in question *I. Fortunei* is given as synonymous with it. Now the plant in cultivation under the name of *I. Fortunei* differs in several respects from *I. crenata*, sufficiently so at all events to be worthy of recognition as a distinct variety. *I. crenata* itself is a low dense-growing bush with small, dark green, lanceolate leaves, about an inch in length, while *I. Fortunei* is more erect in growth, and the leaves are much rounder. The variegated form has the leaves more or less mottled with a beautiful golden colour, some being nearly all of that hue, while others are almost green; the variegated foliage, however, predominates to such an extent, that the whole plant wears quite a golden hue. All the above are very pretty dwarf shrubs, well suited for small gardens, as they are of very slow growth, and at all seasons bear a bright and cheerful appearance. For this reason they may be employed as pot plants for furnishing cold and draughty spots, where more delicate subjects would be injured, or for window boxes and balconies. *I. crenata* was introduced from Japan by Fortune many years ago, and is perfectly hardy in this country. There is one peculiarity connected with these little Hollies, and that is, they can be readily struck from cuttings, which is not the case with any of the other kinds. The most successful way of striking them is to take the current season's shoots about July, and, after removing the bottom leaves, dibble them into pots of sandy soil and keep in a close frame till rooted. They may also be grafted on the stronger growing kinds, but as they strike root so readily such a mode of increase is not needed.—T.

No. 802. SATURDAY, April 2, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

MARKET SALES OF GLASSHOUSE PRODUCE.

The following was sent us some time ago, in reply to a query published in *Gardening Illustrated*:—

If "Amateur" intends growing for Covent Garden or any other London market, he may be assured that, unless he can sell his own produce in the market, he will be completely at the mercy of the salesmen to whom he may consign his goods. They return what price they choose, and in a general way it is most difficult to ascertain if one is fairly dealt with. The editorial recommendation, to select a trustworthy house, is good, but, as the following instance will prove, it is not an easy matter to distinguish the true from the false. Having this winter a quantity of flowers that I knew would be in good demand about Christmas and the new year, I thought that, instead of following my usual custom, of sending the lot to "a reliable man," I would divide them. I selected two of the largest and oldest-established houses in the market. I sent about the same quantities, of exactly the same quality, on the same days, and the result was on the first consignments a difference of one-fourth between the prices of the two firms. The disparity in price continued in an increasing ratio until at the beginning of the year there was exactly one-half difference in the returns from the two firms. Nor was this all. The firm that gave me the low price charged 10 per cent. for selling as against 5 per cent. of the other. It is needless to say how I acted under such circumstances; but I certainly have good reason to say that if the price returned by one firm was a just one, I was fearfully cheated by the other. Had I only sent on one day, I should not have thought myself so badly done by, as one day's sale is really no criterion; but it was the same every time. I may say that, although I have been familiar with Covent Garden for a good many years, I never had a greater "eye-opener" than this. I have hitherto put my produce in the hands of some old-established man; but I will trust no one in future. I will act in the same way with my fruit as with my flowers, for I see that a reputation for respectability is not a guaranteed against unfair treatment. As many besides amateurs are probably interested in market-culture, I have thought that the above details might be useful. I would advise anyone having choice produce, whether of flowers, fruit, or vegetables, to do as I did with my flowers. They will then not be absolutely at the mercy of one individual, and will get the current market price, whatever that may be. Another important point is to insist on having an invoice of sale on every sending. This is your only means of proving, in case of error, that you have sent the goods. But for this I should have lost money again and again. Never trust a man who will not attend to this. There is one fact in connection with the selling of market produce that some may like to know. The large growers of plants and flowers have stands in the market, which they occupy throughout the year. Those who send produce only occasionally, or who grow in small quantities, would not find it worth their while to do this. It is, however, open to them to engage a place in the flower market for a few hours only. This is obtained on application to those in charge every market morning, the toll being levied in a very fair manner. The would-be seller exhibits his produce, and the toll is computed by the quantity thereof. For about a shilling one may procure the convenience of sell-

ing a small number of pot plants or flowers.—*J. C. B.*

This is a very important matter, and we called the attention of Messrs. J. W. Draper and Son, the well-known foreign fruit brokers and auctioneers of Covent Garden—the leading house in the market—to this, and other letters that we had received. We suggested to them whether, bearing in mind such facts as are here set forth, it would not be a good thing to open in the market public auction sales of the produce of our English gardens. They at once responded to our suggestion, and now inform us that, although they cannot undertake English outdoor produce, they are ready to conduct sales of hot-house produce, fruit, and cut flowers three days a week in Covent Garden—viz., on Mondays, Wednesdays, and Fridays at 10.30 a.m. The advantage of this, we may point out to some of our readers, is that, as the sales will be public, the prices will be put on record, the firms will simply charge a fair commission for work done, and the whole thing will be above board and direct. We look upon it as an excellent step towards placing on a better footing much of our market-garden cultivation. At the present time, arrangements in the market are such that market growers have to attend at very early hours in the morning, and the private growers, when they feel disposed to market their goods, have serious difficulties to contend with. We strongly urge our readers to support this experiment.

ROSE GARDEN.

T. W. GIRDLESTONE.

PRUNING ROSES.

PRUNING ROSES is also very useful as a means of controlling to some extent their time of blooming. By this it is not meant that to obtain early blooms Roses should be pruned very early in the season, for very often Roses so treated would have their young growths all cut off by a late spring frost, and their flowers would be no earlier than those of the latest pruned trees. But if it is desired to prolong the blooming season, a considerable extension of time may be obtained by pruning the shoots to different lengths, cutting back some but little, others more, others very hard. The less a Rose shoot is shortened the sooner will its flowers be developed, and they will be produced later just in proportion as the shoots are cut hard back.

It is not impossible that the alleged lateness of the Rose seasons now, compared to those of former years, may be to some extent owing to a general adoption of a closer system of pruning than that formerly in vogue; for it may be looked upon as a fairly-established fact that there will be a greater difference in the time of flowering of Rose trees of the same varieties similarly situated where the shoots of some are but little shortened and of others pruned very hard than where the shoots are all cut back to the same length, though some be pruned three or four weeks later than the others. The topmost eyes on a Rose shoot are always the most precocious, and if these are allowed to produce flowers, the blooming time, where the growth of the trees is not interfered with by spring frosts, will be very early. The eyes half-way down the shoot are less precocious, and when these are cut back to, the flowering is later—although occasionally that of the long-pruned shoots may be simultaneous after a severe late frost, which, of course, would injure most the forwardest growths and throw them back. The eyes at the base of a shoot, however, are the least

excitable and appear the most completely dormant of all, and when plants are cut back almost to the ground, it seems to take them longer to elaborate their new shoots and the flowering is retarded.

On the other hand, the pruning of one half of a considerable number of varieties three weeks before the other half makes little or no noticeable difference in the time of blooming, and numbers of instances have been recorded of the pruning of the two halves (at an interval of twenty-one or so days) of long rows, each planted with one variety, which nevertheless have been ultimately found to flower simultaneously throughout the whole length.

If it is proposed to prune Roses to different lengths with a view to prolonging the flowering season, either some shoots on each plant may be cut hard back and some left longer, or some plants may be altogether cut back and others have all their shoots left more or less long. The latter course is decidedly preferable as making the plants rather easier to manage and as producing a more striking effect in the garden, for in a group of a dozen plants, six in full bloom, while six are still green, make a more brilliant display than if each of the twelve plants carried one or two flowers. The difference in height of the plants, however pruned, will not be very conspicuous, for although the flowering growths produced high up on a shoot are short, yet the elevation from which they start maintains them at a fairly high level, and the shoots produced from the base of a plant, in spite of starting from so near the ground, nevertheless make a much stronger and longer growth, so that they ultimately quite overtake those that began 18 inches or 2 feet above them.

This mode of pruning is only available for prolonging the period of blooming of Roses which are thoroughly perpetual in character, for it must not be forgotten that the cutting down of the strong-growing summer Roses almost to the ground merely results in immensely vigorous flowerless shoots. Consequently, a good way to treat these very strong shoots is to peg them down parallel to the earth, when the buds break much more evenly than if the shoots are left erect, and the bed also is much more completely furnished. Treated thus the Austrian Briers and the Moss Roses especially make effective beds; where the dark Moss Lanci is grown, its 6-foot and 8-foot rods cannot be better employed than thus pegged down, when they will produce flowering laterals throughout almost their entire length; and the crimson Captain Ingram and the white Blanche Moreau are also similarly available subjects. The pruning here resolves itself into the removal of the old wood that has already flowered, and then the young shoots are disposed to the best advantage, very much after the fashion in which Raspberry canes are dealt with.

In all the above remarks on pruning, the flowers either individually or collectively have been the principal consideration; but when it comes to pruning large specimen Rose trees, numerous other points have to be taken into account, and it may not infrequently be found necessary to leave shoots which cannot carry good flowers in order to avoid producing a lop-sided plant.

NEW AMERICAN ROSES.

THE Bride is by far the best white Tea in cultivation, and when well grown is as large as the finest Cornelia Koch and a much freer bloomer. As regards other new Roses, I saw some flowers of a Hybrid Tea shown in New York recently which promised to be very fine. It is said to be a free bloomer under the same treatment as *La France*, and grows on stiff stems much like *Paul Neyron*, which it somewhat resembles. The raiser informed me he had other seedlings which promised well. *Papa Gontier*, a French Rose, sent out a few years ago, has been brought out again this year, and the buds sold well, but unless it is extra well grown I doubt if it is better than a *Bon Silene*. I saw it shown in November very fine, and it was claimed that when expanded it did not show the pale semi-

double centre of *Bon Silene*, but when shown recently in a warm room I could not see any difference. Opinions at present differ as to the merits of Bennett's *Rose Puritan*. I have not seen it growing, but those who have are not very enthusiastic about it. I saw it exhibited at Philadelphia and was pressed for an opinion, but answered, I would like to see it again. Her Majesty so far has been a failure in this country, and although it is not wise to condemn a new *Rose* the first season, it has not shown good qualities with any grower. I have seen it with shoots 10 feet long and thick in proportion, and also when it was tried for early forcing, and would not grow an inch. The first time *Andre Schwartz* ever was shown—in fact, the only time it was shown—the grower was anxious for our opinion. It was poor as exhibited, and I had seen the plants a short time before. He wanted to sell, with our recommendation. I told him it was worthless, and he owned afterwards that my opinion was correct. Mr. Peter Henderson holds the stock of a new *Rose* called *Dinsmore*. This he thinks will be a good outdoor variety. It is evidently a free bloomer, but probably too double for forcing. I have not seen it when expanded.

We have had the darkest winter I have ever seen in this country, for even when we have had a clear night it would rain and snow in the day; in fact, we had both rain, snow, and frost about every other day. It was very bad for forcing; many *Roses* came pale; the favourite *Rose*, *Perle des Jardins*, from that or other causes, has been a partial failure. The early Hybrid Tea varieties have not flowered so freely as usual. I am cutting fine blooms of *Paul Neyron* and *Magna Charta* with stems 2 feet long. *La France* has been troubled with black spot, and so has *American Beauty*. This is a very sweet *Rose*, and fine in the early part of winter. It would probably do well outside in England. Though only sent out last year, it has been very fine in many places.

Maywood, New Jersey, U.S. JAMES TAPLIN.

Hyacinths at Highgate.—The Messrs. Cutbush have for so many years been celebrated as *Hyacinth* growers and exhibitors, that it is not surprising that these plants form a marked feature of their home spring show. Amongst the kinds most deserving attention we noted amongst the reds, *Howard*, very fine spike with large bells, orange-crimson; *Macaulay*, deep rose, striped with crimson, spike very large; *Etna*, deep pink; *King of the Reds*, *Von Schiller*, deep salmon-pink; and *Solfaterre*, bright orange-scarlet. Of whites, the best were *Snowball*, *Mont Blanc*, *La Grandesse*, *gigantea*, *Baroness Van Tuyl*, and *Sweetheart*. These all have fine spikes and large white bells. Of the blues, *Marie*, dark purplish; *Sultan*, deep purple; *William the First*, purplish black; and *Minosa*, are the most remarkable of the darks; whilst the best clear and light blues are *Charles Dickens*, *Grand Lilas*, *Czar Peter*, *Grand Master*, *Princess Mary of Cambridge*, and *King of the Blues*. Yellows are not numerous, but some of them are excellent, the most notable being *Ida*, pale yellow; *Bird of Paradise*, deep yellow; and *Sonora*, nankeen-yellow.—G.

Hyacinths at Holloway.—Mr. Williams' nursery is so intimately associated with *Orchids*, that one is rather surprised to find a group of some five or six hundred *Hyacinths* of their own growing arranged to great advantage with small *Palms*, *Dracunas*, and other ornamental-foliaged plants in the large conservatory. These bulbs were potted early, and have been brought forward very slowly, with the view of bringing them into bloom about the middle of March. To accomplish this, Mr. Williams says, care and watchfulness have been necessary, as some of the varieties needed a great deal of retarding, whilst others required an extra amount of heat to bring them into bloom just at the appointed time. In addition to the kinds which we have mentioned elsewhere, we noted the following as being extra fine: *Cavaignac*, salmon, striped rose; *Duchess of Albany*, pink; *Henry Havelock*, purple-lake; *Lina*, bright crimson; *Pellissier*, deep crimson; *La Noblesse*,

white; *La Belle Blanchisseuse*, pure white, large spike; *Distinction*, light blue; *Grand Lilas*, azure-blue; *Lord Mayo*, bright violet; *Haydn*, dark purple; *L'or d'Australie*, deep yellow; *Obelisque*, citron; and *Marchioness of Lorne*, striped creamy orange. All these are worthy the attention of those desirous of choosing colours for next season's forcing.—G.

DEATH OF MR. JOHN McHUTCHEON.

WITH great regret we have to announce the death of Mr. John McHutcheon, assistant editor of *THE GARDEN*, who died on Saturday, the 26th March. No other man had so long an experience of gardening journalism, he having been, before joining *THE GARDEN*, over twenty-five years with Dr. Lindley on the *Gardeners' Chronicle*. No one has passed so much garden lore through his hands. For over forty years the writing of the best gardeners in England was prepared for the press by him—himself a gardener. Such experience led to the acquisition of a mine of gardening knowledge and to excellence as a judge of the value of gardening writings. The sentence-without-head-tail-or-joint-men; the writers who break a man's heart with the very look of their absolutely illegible manuscript; the clever man who has a live nettle for application to his brother writers; those who write accounts of beautiful gardens as pleasant to read as an auction catalogue; the men who trot out the same old article on "winter-flowering plants" for the eighth time within the over-burdened memory of the editor; the generous distributors of puff paragraphs; the numerous correspondents who want to get bold advertisement in the body of the paper; the men who object to being edited, and who sprinkle their MS. with errors; the writers who say in French what could be better said in English; those who write for gardeners in Greek and Latin (often bad)—all these, and many more, he had to guard against night and day. A great eradicator of weeds, ever seeking flowers and fruit among ranker herbage, and ever patient so long as there was the least chance of finding any! So strong a mower, when swishing his scythe through Docks and Twitch, now and then perhaps cuts down a pretty alpine flower or delicate annual! If met by a number of irate gardeners, soon after he had robbed them of their flourishes, we fear they would have punished him; but many of those he edited would be the first to speak well of his work. Those who deal with established journals have often an easy task compared with that of the beginners! Trouble may be got over when the ship is anchored in smooth water. But when our so-called *Venture* sailed first it was a time when we had to "Do or Die," and then "Mac" did his duty—faithful as an Oak-leaf. And so we sailed away ever since, and after many days got into pacific seas and even among the flowery islands. For a long time past Mr. McHutcheon had struggled with a bronchial affection, during the past winter more severe than before, and he passed away quite peacefully and happily last Saturday morning. Faithful, loyal, kind, good-hearted, ready to help others, the belief

among his friends is that he never had an enemy. He certainly never deserved one.

John McHutcheon was born in 1819 in Ayrshire, in which county he spent his young days. As a boy he learnt gardening in the neighbourhood of his home, and afterwards worked in some of the best gardens in the lowlands, including those at Oxenford Castle, which place he left to come to London when about twenty years old. He first stayed for a few months in Messrs. Jackson's nursery at Kingston-on-Thames, and afterwards went to the Royal Horticultural Society's garden at Chiswick, then enjoying prosperous days. He had not been there more than a year or so when Dr. Lindley, requiring an assistant on the staff of the then newly-started *Gardeners' Chronicle*, selected him from among other young men for the post. He would have been sixty-eight years of age on the 31st of March.

Amaraboya princeps.—The above-named most beautiful *Melastomad* is one of the recent introductions of the *Compagnie Continentale d'Horticulture*, hitherto of Ghent, but who are on the point of transferring their business to Brussels. This most lovely plant is well figured in the second number of the enlarged issue of *l'Illustration Horticole*, and is a cool stove shrub with handsome foliage resembling that of *Medinella amabilis*, dark shining green above with red under leaf. The flowers are borne in large bunches and are of large size, of a deep rose colour with a pure white throat. It is a native of New Granada, and two other species are known, *A. splendida* and *A. amabilis*. This fine plant should be a great acquisition to all collections of stove shrubs.—W. E. GUMBLETON.

Begonia Gloire de Sceaux.—This *Begonia* has often been recommended as a valuable winter-flowering variety, yet, notwithstanding this, it is but sparingly distributed. It cannot be relied on to bloom in the early winter; indeed from Christmas till May appears to be its usual season, so that the blooms are just now at their best. This *Begonia* is of a stout, vigorous habit, and it naturally assumes a pyramidal habit, densely clothed with foliage. The leaves are large, and of a peculiar dark metallic green tint. The blooms are borne freely in good-sized clusters, and are of a pleasing shade of pink. The individual flowers are larger than any others of the same class; indeed, such as would have been considered a few years ago as very good in the summer-blooming, tuberous-rooted section. This *Begonia* was distributed by Messrs. Thibaut and Keteleer, of Sceaux, and announced by them as the result of a cross between *B. socotrana* and *B. subpeltata*.—H. P.

Spiræa Thunbergi.—This *Spiræa*, which is one of the earliest to bloom in the open ground, will flower well under glass; indeed, quite early in the season a few days in the forcing house will serve to bring out its pretty little white blossoms. It forms naturally a free-growing, but not a large bush, with long slender branches and small pointed leaves, which especially when first expanded are of a bright green tint. The branches curve over in a very graceful manner, and when thickly studded for a great part of their length with clusters of small Hawthorn-like blossoms, the whole plant bears a very attractive appearance. It is of a free-rooting character, and will do well if potted up in the autumn. Treated in this way the roots soon commence to be active. Sprays of it thus early in the season are very useful in a cut state for furnishing vases, but the blooms do not long remain in perfection when treated in this manner. Besides doing well under glass, it is one of those kinds that should be made a note of by the lover of hardy shrubs, as with plenty of room to develop itself the whole contour of the plant is most graceful, and its early blooming quality is also another recommendation.—T.

FLOWER GARDEN.

A RAMBLE AFTER ANEMONE FANNINI.

THE above plant is now hardly known in England, though for a long time botanists have been aware of its existence. Twenty-two years ago Harvey described it as "a noble new species of *Anemone* with flowers fully larger than those of *A. capensis*, and broad, digitately many lobed, thick, and softly velvety leaves: a most desirable plant to introduce into gardens." Some account of an expedition in search of this plant may interest your readers.

Starting on horseback from Maritzburg, 2000 ft. above the sea, one bright January morning, a 10-mile ride brings us to the base of one of those hills which encircle the capital of Natal on every side. Here and there one sees the annual garden *Convolvulus* covering the bushes with white, red, and purple flowers, sometimes mixed with the orange-yellow flowers of the climbing *Littonia modesta*. Dismounting, we begin our upward ascent, for 1000 feet must be gained before we reach level ground again. It is a stiff pull, but a thunder storm refreshed the earth last night, the sun is not yet very high, and the air is clear and cool. Trailing about is an *Ipomœa* with a large tuberous root, soft hairy leaves, and massive deep purple flowers.

Thick Grass clothes our hill with a few bushes, consisting of a *Cussonia* with its elegant Aralia-like leaves and huge, candelabra-shaped spikes of dull, green flowers; *Dais cotinifolia*, rich in thick heads of bloom; and a few thorny *Acacias*. *Gladolus Ludwigi* is just showing flower, and some fine, white, brown and green *Gomphocarpus* hang out a last few blossoms, for early spring is their best time. With us, the longest day passed five weeks ago. This mountain-side is the habitat of a singular *Habenaria* about 1 foot high with white and green flowers: sepals green, nearly alike, two large spoon-shaped petals, and a long strap-shaped trifid lip with pendent spur. The stigma is triangular in shape with two curious processes in front; pollina two, at the back of the stigma. *Gazania serrulata* opens out its showy yellow flowers to the morning sun. In swamps the snowy spathes of *Richardia africana* overtop the Grass; near by is a showy purple *Melastomad*, *Osebeckia Umhlangiana*, and the beautiful blue *Agapanthus umbellatus*. This last-named, I observe, varies a good deal in size and colour of flowers.

At last we reach the summit, and, looking back, see the white houses of Maritzburg lying 1000 ft. beneath us, encircled with huge squares of blue-black *Eucalypti*. Now, mile after mile, we canter along the undulating grassy hill-side, breathing the fresh air, but higher yet our road leads us, till we halt by a clear, sparkling mountain stream, 4000 ft. above the sea, and, dismounting our horses, turn them loose to enjoy the luxury of a roll and a graze on the juicy Grass, refreshing ourselves the while with the contents of our sandwich-box. A very showy white *Eucomis* grew in moist places hard by with a flower-spike some 3 feet high—*E. punctata* var. *alba*, probably. Overtopping the *Eucomis* was a fine *Chlorophyllum* (*Liliaceæ*), about 5 feet, good, showy white flowers, nearly half an inch across. Here, too, is *Pentansia variabilis*, that widely spread plant, for I have met with it up country in the latitude of Madagascar; it is a many-stemmed, prostrate herb with large heads of deep blue flowers. Some distance off a patch of deep golden yellow attracted our attention. It proved to be a terrestrial Orchid—*Eulophia ensata*: one plant bore forty-two thickly crowded golden flowers. Near by was another *Eulophia*, yellow petals and dark maroon lip, very handsome, but rarely met

with. Here, too, growing in moist black peat is *Nerine flexuosa*, *Satyrium carneum*, and *Disa polygonoides*. Plate 6532 in the *Botanical Magazine* does great injustice to the last-named plant, as I have seen it 3 feet high, bearing flowers along one half of its stem. Miss North's pictures alone do true justice to our flora—they seem to me beyond praise. All the summer rain and mist hang about these hills—often the temperature varies from 50° to 60° at midday in the shade. In winter it is much colder—frosts nearly every night, with, however, little or no rain. Last winter in a garden up here a large *Tacsonia Van Volxemi* was killed outright, and *Fuchsias* have to be brought indoors to keep them alive.

But the sun is mounting higher, and our destination, a solitary mountain top, is seen still far ahead. On again, still upward, and now we note some plants never found but on very high elevations. *Tritonia natalensis* is sending up a long coral spike; the shrubby purple-flowered *Vernonia mespilifolia* shows up a large blue Campanula, *Buddleia salva-folia* and a tiny purple *Mesembryanthemum*. By degrees our pace is reduced to a mere scramble, so we dismount and tie the horses to a shrub—*Paretta Bowkeri*. A few more steps upward, and growing amongst crevices of the granite

Cape Pelargonium Pretty Polly. Engraved for THE GARDEN from a photograph.

rock we find the object of our search, *Anemone Fannini*, at an altitude 4300 ft. It is really a superb plant, whether we look at the massive dark green, deeply lobed, velvety leaves 18 inches across, or the snow-white flowers larger than half-a-crown, borne on 3 feet high stems. Mixed with it is the beautiful *Watsonia densiflora*, with its thick crowded rosy purple spikes; here also is *Cynium racemosum*, a very handsome mauve *Scrophulariæd*: its common name is the Christmas Flower. One more sub-alpine plant is *Gerbera aurantiaca*, a vivid scarlet Composite, in appearance not unlike a much magnified English Daisy. A last scramble up a series of great altar like steps and we are on the summit of a flat topped mountain, not more than 10 yards across, roughly circular in shape, elevation 4500 feet.

This plateau is composed of horizontal granite rock, only accessible by the way we have come; on every other side is a fearful precipice some 800 feet down. The view is most extensive from the Drakensberg on the west to the mountains on the east of Maritzburg—not less than 100 miles across. A note of the plants found on the summit growing in black mould in rocky clefts gives the following: *Aloe* sp., *Asparagus* sp., *Buddleia salva-folia*, a dwarf *Chlorophyllum*, *Paretta Bowkeri*, *Greyia Sutherlandi*, *Richardia melenauca*, a Labiate, a *Lycopodium*, and a few Grasses and Ferns.

A bitter cold wind made me soon beat a retreat down again, and I was glad at the close of the day to find myself back in town in a much warmer part of the country.

R. W. ADLAM.

Maritzburg, Natal.

CAPE PELARGONIUM PRETTY POLLY.

THIS pretty old favourite is a charming plant to put out in summer, blooming steadily throughout the warm months, a quality which cannot be claimed by many of the more showy allied sorts, whose culture is generally reserved for the greenhouse. In colour it is a lively salmon-rose, with crimson blotches: the leaves are strongly and delightfully scented.

Border Carnations.—Now that the time for spring planting has come round, one of the first families that deserve attention is border Carnations. Get them into their blooming quarters early and half the battle is won. Why is it we hear so many complain that these beautiful flowers prove unsatisfactory with them? The reason is, in the majority of cases, owing to their being planted too late, so that the plants do not have time to make proper growth. This is often done under the mistaken idea that they are tender. I have for many years planted out large quantities of them, and my plan is to commence about the middle of February, and continue on all favourable occasions to the middle of April. Plants kept in pots after that time get starved, thin, and drawn. Last year I bought some, and they ran up with just one flower-stem, but did not make any Grass, and my plants are all dead. This is generally the result of late planting. To lay the foundation of success, plant this superb family early.—F. G. Tottenham

A pleasing contrast.—Some time ago a note appeared in THE GARDEN calling attention to the merits of *Solomon's Seal* for forcing. Having forced it for several years, I can speak highly of it for the purpose. We manage to have a few pots of it in flower from the end of January onwards till it flowers out of doors; but we use it freely for another and more appropriate purpose, that of planting in odd corners and near the base of shrubberies, where it is very effective. In one particular spot at the foot of some shrubs we have a large patch, over which some Ivy has been allowed to run. When in flower this is a very pretty sight, the long, arching spikes set in their groundwork of green being very showy. Their beauty, however, does not end here, for as the growths ripen they take on a bright yellow tint, which forms a pleasing contrast with the carpet of Ivy beneath.—E. B.

Seedling Carnations and Pinks.—The first week in April is a good time to sow Carnation and Pink seed. It will vegetate most freely in a hot-bed where the heat is not too violent. I raise about a thousand plants every year of the different sections; sometimes we give the most prominence to the scarlet bizarre Carnations: at another time, the red-edged Picotees. Last year we flowered a lot of purple-edged Picotees, and it is rather remarkable that there were amongst them some very handsome purple self Carnations, some heavy-edged purple Picotees, but very few light-edged ones like *Her Majesty*, from which the seeds were saved. This year we will be raising a number of yellow-ground Picotees, but even these sport in the most fantastic manner. Those who may purchase packets of Carnation or Picotee seeds must not expect, on the one hand, to have all flakes and bizarres, or, on the other, edged Picotees. There is also from 10 per cent. to 15 per cent. of single varieties, many selfs, and a large number of nondescripts. They are all interesting, however, and well adapted for cutting in flower and bud with long stems. The healthy glaucous foliage must not be cut off and some other foliage substituted, as even Carnations and Pinks are best when arranged with their own foliage. The cultural details are very simple. Prick out the small seedlings 2 inches or 3 inches apart in boxes, and when they are inured to the open air, let them be planted out a foot apart in lines, beds, or borders. The plants

like a generous, deep soil, with free exposure to light and air. Pinks require quite the same treatment. The beautiful laced flowers on a glistening white ground are most esteemed, and those with a great bunch of small petals are not so pretty as those with a smaller number, but broader, and on which the margin is better defined.—J. DOUGLAS.

Hellebores at Manchester.—At the recent spring show of the Manchester Botanical and Horticultural Societies, one of the leading features was a group of seedling Hellebores, shown by Mr. Samuel Barlow, Stakehill House, Castleton, Manchester, and to which the society's Jubilee gold medal was awarded. As many as twenty-five fine hybrids formed the collection, and the colours ranged from varied shades of light purple, purple suffused with green, and whitish green, flaked and speckled after the manner of some of the prettiest of the hardy Rhododendrons; the plants had been grown in pots, and the flowers were lifted upon slender stalks to the height of 18 inches or 20 inches above the ground in loose clusters of five or six, and with sufficiency of young, green foliage as bases to the heads of bloom. As parents, Mr. Barlow made use of *H. abchasicus*, *H. colchicus*, *H. olympicus*, and one or two others. It occupied five years, and in some cases longer, from the time of sowing until the seedlings flowered. Thus, patience is required in raising and blooming seedling Hellebores, as in the case of seedling Tulips. Mr. Barlow grows a large quantity of Hellebores in pots at Stakehill; and the mid-winter-blooming species and varieties had, as might be expected, gone out of flower.—R. D.

Wachendorfia thyrsoiflora.—Anyone in want of a good, bold, showy subject to take the place of *Gentiana lutea* where that does not do well cannot do better than procure this really handsome plant, which has proved perfectly hardy in the open air in this country, having withstood the severe tests of the last three or four years. It is growing in a rich, peaty bed well sheltered from the cold east winds, and although the foliage gets a little destroyed, the crowns do not suffer in the least, and are always ready to shoot up at the approach of warm spring weather. For bold foliage alone it is well worthy a place in the garden. The leaves are a yard long, 3 inches or 4 inches broad, prominently ribbed, and of a bright green, the mid-rib assuming a reddish tint, which becomes more intense towards the base; the flowers, somewhat resembling those of *Gentiana lutea*, are yellow, and produced in profusion on dense spikes a yard or so high. It ripens seed freely, and the plants, well attended to when in a young state and grown on, make good flowering specimens the second year. It can also be increased readily by division of the roots, which is best done in autumn. It would, no doubt, prove a valuable plant for marshy places, or close to the margins of artificial lakes, &c., as it grows better in moist than in dry situations.—K.

Violets failing.—"J. C. C." in THE GARDEN (p. 279) fancies his Violets have done badly. I should consider that he has been fairly successful with them if he has been able to gather a bunch two and three times a week during the winter. I should consider that ample in the depth of winter. Of course if anyone requires more, the only thing necessary is to provide more pit room for them. I do not think the best grower extant could gather more than thrice weekly in the depth of winter. A few years ago when I had charge of a garden in the suburbs of London I tried every conceivable way to flower Violets, but could not succeed. And yet, strange to say, not more than a mile away they not only grew, but flourished and flowered most profusely both inside and out. I have not much difficulty here in producing a good supply of flowers, and my method may be explained in a few lines. After they have done flowering I take off a sufficient number of rooted cuttings or runners and plant them in a specially prepared plot of ground about 18 inches apart each way. As they increase in size all the runners are carefully picked off, the ground kept free from weeds, and when dry a good soaking of water is given. About the first week in October, a pit that has been used for growing Melons is specially prepared for them. I clear away all the Melon soil (leaving the fermenting material) and fill up the frame with the following compost, viz.: To every three barrow-loads

of loam I add one of leaf soil, a peck of soot, and one peck of bone-dust. This should be thoroughly mixed a few weeks previous to being used. When put in the pits the Violets are taken up carefully with a good ball and planted a foot apart, and kept shaded and close for a few days, after which the lights are taken off when weather permits, closing them partially at night. We generally commence gathering flowers about the end of November. I herewith send you a gathering of three plants, which have not been specially treated in any way.—W. A. COOK, *Holme Wood, Peterboro'.*

* * A nice gathering of blooms, the flowers large and the foliage very healthy.—ED.

A BORDER OF WHITE FLOWERS.

It is part of my duty to fill two long wide borders, situated in a prominent part of the kitchen garden, with a variety of flowering plants, the aim being to make them both ornamental and serviceable. Not only are these borders supposed to be kept as gay as possible during the summer and autumn months, but they must also be made to furnish large supplies of cut flowers. At one time only a few kinds of plants were grown, and these were in straight lines. Of late years we have gradually broken away from this hard and fast line, and a mixture of herbaceous and various other plants less showy perhaps than Pelargoniums and Calceolarias, but infinitely more beautiful and serviceable, has been used. A well arranged mixed border or large bed ought never to be thought monotonous, but a change even in this is acceptable occasionally, and it occurred to me a mixture of wholly white flowers would prove very pleasing. In carrying out this, as it proved, happy idea, we not only created a very pretty effect, but also grew a very profitable lot of white flowers for cutting from, these being more in demand than all other colours. In order to make my notes as instructive as possible, I will both give the list of plants that can be used in these borders or beds of white flowers and also a few cultural details.

DAHLIAS.—For the back rows of a border or the centre of a bed Dahlias are most serviceable. Constance or Ariel, a very old favourite in this district, and which is usually catalogued as a *Cactus Dahlia*, grows to a height of 4 feet, is very branching in habit, and towards the autumn yields large supplies of beautiful semi-double blooms, which are much prized for wreaths, crosses, and church decoration. Mrs. Tait is rather more free flowering, and the edges of the petals are much serrated. It is a good companion for Constance. For planting in the second or even in the back row we have Pompon Guiding Star or White Aster, which grows about 3 feet high and is wonderfully free and useful for cutting from. Lady Blanche, another Pompon and rather smaller, is also a desirable sort. Of single flowering sorts there are few to surpass Alba or White Queen, this growing to about 3 feet in height and flowering abundantly. Dahlias may be increased either by cuttings or by dividing the old stools. For affording cuttings the old roots should have been started in gentle heat early in March. When the shoots are about 4 inches long they should be cut away cleanly from the old stem, in this way securing a small heel with each, though cuttings may be rooted without this, providing they have not become hollow. Dribbled singly in the centre of a 2½-inch pot filled with sandy soil, plunged in a gentle hotbed covered with a hand-light, watered in and kept rather close, though not sufficiently so to cause damping, they will soon strike root. Before they become drawn they ought to be removed to a shelf in a cooler house, and they may with advantage be given a shift into 5 inch pots before they become root-bound. In this manner strong healthy plants will be available for planting out late in May or early in June, and which if properly hardened off soon commence growing rapidly, surpassing plants raised by division, and also the old stools which may be planted intact. If they are to be increased by division the old plants should be started in gentle heat some time in April, and

when the shoots are a few inches high the old stem may be split up into several pieces, it being necessary that one or more tubers form part of each. These should be potted singly into 6 inch pots, or less if possible, and be kept in heat till fresh roots are formed, when a cold frame is the best place for them. We reduce divisions to one shoot, a single stem being preferable to two or more. Dahlias delight in a rich well-worked soil, and ought always to be kept closely staked and tied up, or otherwise the first rough wind greatly disfigures them. It may not be out of place to add that the sorts above named can be purchased in quantity and cheaply, a whole row of them being most effective.

JAPANESE ANEMONES.—The white variety known as Honore Jobert ranks among the most beautiful border plants, added to which it possesses the additional merit of being perfectly hardy and easily propagated. It is suitable for arranging next the Dahlias, as it grows to about 3 feet in height. We find the best time to transplant this Anemone is just as active top-growth commences, and if all the strong crowns are lifted and planted in groups, three or more in number, they soon spread all round, and may remain undisturbed for at least four years. Every strong root appears capable of creating a large progeny, numbers of young plants soon filling the ground from which the old ones were lifted. A strong loamy soil appears to suit this section of Anemones best, and with us they usually flower freely till severe frosts cut them down, affording unlimited quantities of charming cut flowers.

SWEET PEAS.—Although the coloured varieties are certainly the most beautiful, several good novelties being recently added to the list of these, we yet value the old white sort, and grow either a row or several patches every season. They are either sown in the open ground early in April, or raised under glass and planted out later on. The latter plan is preferable where slugs are troublesome. Added to this, Peas raised in pots can be more easily arranged with the other plants. We sow about a dozen seeds in each 5 inch pot, these having been previously filled with good loamy soil, and place in a cold frame till the plants are planted out. They are suitable for the back rows, and require to be supported with a light circle of stakes not less than 3 feet in height. On strong soil they require taller stakes, as they continue to grow and flower nearly all the season, especially if the seed-pods are gathered as fast as they form.

ROSE BOULE DE NEIGE.—This ought to find a place in every border of white flowers. It is of free growth, whether on the Brier or Manetti stocks, or, better still, on its own roots. The blooms are not large, but they are perfect in form, beautifully white, and most abundantly produced nearly all through the season. The foliage, too, is distinct and useful; and altogether it is one of the most valuable sorts in cultivation. Neither this or any other Rose will long succeed in a poor border. They require a good loamy compost at the outset, and annual mulchings of good manure. *Boule de Neige* should be freely pruned, the strong growths which follow branch and flower continuously, and in this respect also differ from the majority of Hybrid Perpetuals.

ZEAL JAPONICA.—This striped Japanese Maize is effective in any kind of mixed border or large bed, and singularly so when associated with white flowers. It is of free, elegant growth, and suitable for planting in the front of or among Dahlias and other back-row flowers. About the middle of April is a good time to sow the seeds, as if sown earlier the plants are liable to become stunted before they are put out. They transplant easily from pots, and if the seed is sown in pans it is advisable to place the required number of plants singly into 3½ inch pots, this being done when the second leaf is showing. We usually sow the seeds singly in small pots, place them in gentle heat, eventually hardening off the plants and transferring to the borders early in June. A rather poor soil is best for them, the reverse inducing a rank and but little variegated growth.

MARGUERITES.—There are no more showy border flowers than this class of *Chrysanthemums*. They are suitable for the middle line of either a border or bed of white flowers, and if the soil is not very rich they will flower abundantly from the time they are put out till severe frosts intervene. We have frequently potted up strong plants as late as November, and these have continued to flower up to Christmas. The old coronarium frutescens is one of the best for the borders, none of the others that we have tried being so free and continuously flowering. *Halleri maximum* is better for cutting from, but is scarcely so good in the open as it is in pots, being apt to grow too strongly. Plants struck in the autumn and wintered either in pots or boxes, in every respect similarly to zonal *Pelargoniums*, are preferable to spring-struck cuttings, as they are effective from the first. Failing these, cuttings may yet be struck in gentle heat, and if duly stopped, potted oil, or disposed thinly in boxes, any sandy soil suiting them, they will be of good size and fit for planting out early in June. *Pyrethrum uliginosum*, also frequently classed with the Marguerites, is of totally different habit and perfectly hardy. At the present time it is throwing up abundance of strong suckers, and these readily transplant, flowering strongly in the autumn. In good ground it attains a height of 4 feet to 5 feet, and is therefore too tall for many beds and borders. It is most effective in groups. Old clumps pay for lifting and replanting occasionally, a few strong growths affording a better display of bloom than a greater number of crowded and weakly ones.

SUMMER CHRYSANTHEMUMS. The earliest to flower and which I can recommend are *St. Mary* and *La Petite Marie*. The former grows to a height of from 18 inches to 2 feet. It is of branching floriferous habit. *Mrs. Cullingford* is of somewhat similar habit, but rather later. *La Petite Marie* attains a height of about 9 inches, is very early and free flowering. Cuttings struck in gentle heat any time in April, stopped once, then hardened off and planted out early, soon become established, and will be in bloom in July. We put in the cuttings thinly, and transplant from the boxes to the borders. It is necessary to winter a few stock plants of each in pots.

STOCKS, ASTERS, AND ANTIRRHINUMS.—We rely principally upon these for forming the second row from the front, and they are both effective in the borders and beds, and very useful for cutting from. The most serviceable Stocks are the white varieties included in the collections of *Early-flowering Autumn* and *East Lothian*, and if an earlier display is needed the *New Forcing Ten-week* should be sown. The latter is comparatively new, and is beautiful in either pots or the open ground. White varieties are included in the collections of *Victoria*, *Paeony-flowered*, and other Asters, or they can be purchased separately. It is a mistake to sow either Stocks or Asters in March, as so many are in the habit of doing, for early raised plants become stunted and flower prematurely; whereas those raised about the middle of April may be kept growing steadily and transplanted almost without experiencing a check. If the seed is sown thinly, either in boxes filled with fine light soil and placed on a gentle hotbed or else sown on soil levelled over a nearly spent bed, it will germinate strongly, and the seedlings, when pricked off where necessary into other beds or boxes of good soil, will be of good size for planting out late in May. We plant in patches, three in each, and after the first watering in, the soil being well enriched, little further trouble is seldom necessary. A packet of white *Antirrhinums* is usually included in the collections, and the dwarf white can also be purchased separately. We are fortunate in possessing a very handsome pure white variety, which annually proves one of our best and most serviceable border plants. We sow the seed early in February on the surface of a pan of fine soil, cover with glass, place on a hotbed, and closely shade till it germinates. When the seedlings are well advanced they are placed in a lower temperature, and eventually dibbled thinly

in a shallow bed of fine soil placed in a frame. From this the plants can be moved with a trowel to their positions in the border. We plant these also in patches of threes. Seedlings thus raised flower strongly in the summer and autumn, and those that survive the winter yield large quantities of bloom much earlier in the following season. It should be the aim of the cultivator to keep these white varieties carefully separated from the coloured sorts, as if a few of the latter become intermixed the effect is marred.

MIGNONETTE, GODETIA, AND PHLOX DRUMMONDI.—These are good front-row flowers, and the seed may be either sown at once where the plants are to flower or in small pots filled with good soil and placed in a cool house or frame. We are obliged to adopt the latter plan owing to the partiality of slugs for the tiny plants reared on the borders. Three plants in a patch or pot are ample, and the seedlings should therefore be reduced to that number. Those in pots ought to be planted out before they are badly root-bound. *Godetia The Bride* is our favourite white sort, and this, as well as the white *Phlox Drummondii*, may be raised and treated similarly to the Stocks and Asters.

VIOLAS PURITY AND VESTAL.—The position being moist and cool, white *Violas* will be found excellent front-row flowers. The cuttings being put in late in the autumn and otherwise treated similarly to shrubby *Calceolarias*, they form capital plants for putting out in April or May. Old plants may also be divided and replanted before hot weather arrives, but they are scarcely so serviceable as the young plants. W. I. M.

Spring flowers.—Notwithstanding the rather unprecedented weather we have been having lately, such of the spring flowers as were showing previous to the snow are now looking wonderfully bright in the places where it has melted; foremost amongst them perhaps stands the vernal Snowflake, presenting a charming picture rising out of a dense tuft of *Saxifraga cochlearis*. *Scilla bifolia*, *sibirica*, and *turica* are hardly at their best, although making a pretty show mixed here and there with tufts of *Galanthus Elwesii* and the single and double forms of the common species. Crocuses are also showing well. *C. Imperati*, the forms of *biflorus* and *vernus*, *aureus* and *susianus* are very useful, *albus* especially for planting in Grass, &c., in the more neglected portions. The quaint winter *Aconite* seems quite at home even amongst the snow, and here and there are patches just able to show their pretty golden flowers and fringed collars above the white covering. *Saxifraga Burseriana* and the varieties *major* and *grandiflora*, as well as the dainty little *S. Frederici Augusti*, are particularly welcome just now. A few of the oppositifolia clumps are covered with blossoms, and where the snow has melted one can easily judge how grand they must be in their native home in early spring.—K.

Jacks-in-the-Green.—The production of *Crimson Beauty Jack-in-the-Green Polyanthus* last year inspired me to specially save and sow seed from some other variety of the tribe, as it is evident that there is a wide field open for the production of really interesting and beautiful spring flowers, as far as these are concerned. Oddly enough, I have from the batch blooming already in a cool house some really beautiful *Polyanthuses* quite devoid of the huge leafy calyx which forms the distinguishing feature of *Jacks-in-the-Green*. That is probably a case of reversion, or it may be of advance; certainly the pips are very perfect ones and richly coloured. One half of the seedlings show the green collar, the rest are ordinary *Polyanthuses*. It would thus appear that seeds of *Jacks-in-the-Green* cannot be guaranteed to come true. It may be due to a preponderance of ordinary coloured *Polyanthuses* in the garden, or it may arise from the common tendency of all sections of the family to vary. After all, it is doubtful whether even the petted and over-praised *Narcissus* can excel the *Primrose* family in variety, beauty, or genuine popularity.—A. D.

Ophiopogon spicatus.—The Snake's-beard, or *Japan Grape Hyacinth* as it is often called, is not easily surpassed as a flowering plant; besides there is the chance of its fruit setting and ripening, which

prolongs its beauty for a much greater period. In the open air, however, this is seldom attained with any degree of satisfaction in this country, although in the south of France and Italy we are told that the fruiting stems are quite a feature in many gardens. When grown in an ordinary cool greenhouse, either planted out in the borders or in pots, its grassy foliage and spikes of bright blue or lilac flowers are very attractive, as also are the bright metallic glaucous fruits, which we have seen in abundance. In fine warm seasons a few are produced in the open, but they are very uncertain. Quite apart from the fruit, however, the bold, tufty foliage and the numerous spikes of *Grape Hyacinth*-like flowers make it a very desirable object. Any ordinary border fully exposed to the south suits it admirably, and if protected from the east and north so much the better. There are a few others in cultivation which are well worthy of a place in the border or rockery, such as *O. spicatus*, *japonicus*, *longifolius*, &c. *O. Jaburan* is a pretty violet sort, and is only surpassed by the variety with the variegated foliage. It is also perfectly hardy, forming elegant tufts of pale amber-striped leaves. They are all easily propagated by division, which is best accomplished in autumn after flowering, or in early spring.—K.

Hyacinths out of doors.—I often see in the gardening press the statement that *Hyacinth* bulbs after having been grown in pots and glasses are of little further use. I always plant mine in a south border after one season's greenhouse culture, and the result is eminently successful, the spike enclosed being a fair average specimen, and produced from a bulb planted out two years ago.—WRAITH.

* A good bloom. We have seen *Hyacinths* flowering many years in succession in flower beds.—Eti.

White Trumpet Daffodils.—Every grower of white Daffodils admits such varieties as *albicans*, *cernuus*, *tortuosus*, and *moschatus*, the latter of the *Pyrenees*, no doubt as types or garden hybrids. The chief men in England—for instance, the Daffodil Committee—dispute the idea of such additions as *Leda* and *Bishop Mann*. If both Daffodils are not distinct from each other, and, in addition, distinct from what is known by Mr. Barr as *tortuosus*, and now growing side by side at Temple Hill, Cork, I will willingly give ten pounds to any society of gentlemen in England as a donation to be disposed of as they wish, provided it goes to aid the afflicted, where gardeners' interests are concerned, orphanages, &c. The way to settle the dispute will be to let the Daffodil Committee subscribe among themselves the necessary sum to defray the expenses of say two members to come and see. If adverse to my statement, viz., that *Bishop Mann*, *Leda*, and *tortuosus* of Barr are not distinct, I will pay all expenses, and in addition the ten pounds, as stated. I see now plainly that I will have to resolve myself into a special Daffodil committee, and name and select my own distinctions in future. To send blooms of Daffodils that are in flower here since February to a meeting of say the 12th or 26th of April next is beyond my power, as the bloom in the south of Ireland is at its best from the 10th to the 26th of March, and to send white Daffodils to Chiswick from the congenial soil of the south of Ireland would be putting treasures into a siek chamber. I sent a collection of white Daffodils and other sorts to the early sitting of the Daffodil Committee, but they could not be reported on, as the English ones for comparison had to be produced from under glass.—W. B. H., Temple Hill, Cork.

Annual Sunflowers.—Seedsmen state that of late years there has been an unwonted demand for seeds of *Sunflowers*. It is a fact that a blaze of *Sunflowers* gives conspicuous dashes of colour to gardens. Someone has styled the *Sunflower* "the king of the flower garden," and there is a kind of regal aspect about it. It is common to see flowers more than a foot across, and the dark centres stand out conspicuously when margined with their broad zones of golden yellow petals. There are dwarf and tall forms of the single, and also of the double varieties. The last-named, when of a fine double character, are very imposing subjects; but the current taste certainly runs in the direction of the single in preference to the double

varieties. Wherever planted, they should have good soil, and while there is much in the quality of the variety, it is also certain that a good soil has a great deal to do with the production of fine flowers. People are very apt to plant Sunflowers in out-of-the-way places, where the soil is poor and uncongenial; and then the flowers are small and spare, disappointing the grower. The Sunflower deserves to be well cultivated, and then its blossoms, whether single or double, are of giant size and grandly developed. In Mexico, whence the common annual Sunflower was introduced, it is said to attain a great height, with flowers large in proportion. The Sunflower is, indeed, a plant of some importance in several ways. In the United States whole acres of land are sown with Sunflowers, for the purpose of preparing oil from the seeds. This oil is very pure, and little inferior to that of the Olive for domestic purposes; it also burns well. In Portugal the seeds are made into bread, and also into a kind of meal, in which form they are found to be an excellent substitute for coffee, while they are utilised for other purposes. There are many varieties of perennial Sunflowers that are of great value as border plants, and many grow them for cutting from at the end of the summer and in autumn. They are best increased by parting the roots about the middle of October, or later, according to the season, soon after the flowering period is over and planting out in good soil. The perennial varieties are generally of tree growth, throwing up many stems and producing large quantities of flowers. Some are double and some single. Some of the best are *Helianthus atrorubens*, *angustifolius*, *decapetalus*, *doronicoides*, *giganteus*, *multiflorus flore-pleno*, *orgyalis*, and *rigidus*, the last perhaps better known as *Harpalum rigidum*.

Double Cinerarias.—When we consider the pretty character of the flowers of the double Cinerarias, it appears strange that they have not made a greater advance in public favour. But although pretty, they are difficult subjects to deal with, which no doubt accounts for their not being more popular. At the same time, with skilful attention they make an acceptable change either in the conservatory or in a cut state, their rosette-like flowers, differing from the flowers generally in bloom at the same time. The number of different varieties has now increased to such an extent that they afford an agreeable variety, as the colours embrace deep purple, magenta, blue, white, carmine, and rose. The double Cinerarias do not like too much heat and but very little sunshine. Though not liking exposure to the sun, they require all the light possible and a moderate supply of air. The best lot of plants I have seen was in flower at the end of April in a cold frame, and shaded by a wall. The condition of the plants plainly showed that the treatment suited them, for the leaves were large and robust, and the stock was much more vigorous than when growing on dry staging and enduring the heated air of a greenhouse. From their condition one could see that there would be no difficulty experienced in getting offsets to increase the stock for another year.—J. C. C.

SHORT NOTES.—FLOWER.

Daffodils, Tulips, Hyacinths.—Would the bulbs flower stronger and better next year if the flower buds were removed this season?—X.

We send you blooms of a seedling *Helibore*, the result of a cross between *colchicus* and *viridis*, the former being the female parent. The leaves are rather like it, but are less persistent, and the blooms are shown up to greater advantage. It is very hardy and of vigorous constitution.—R. SMITH AND CO.

Not so good as *colchicus*; the colour is not so bright, and the addition of the green is of no advantage.—Ed.

I HAVE to correct two errors in my last article in THE GARDEN (p. 226), March 12. The author of *Primula Portenschlagiana* is not Becker, but Beck, and *Primula intermedia* (Portenschlag) was found since 1831, but very rarely. Nevertheless, it is an interesting coincidence that two friends found this scarce plant on the same day in different localities.—O. F., *Letchford*.

ENCLOSE you flowers of a lovely Daffodil which is imported into Hull and sold in all the flower-shops. Its beautiful rich colour is much admired. The variety is unknown to me, and I should be glad if you can give its name and a description of it in THE GARDEN.—J. ALLSOP.

Narcissus odoratus *Campenellii*. This excellent variety, a native of the south of Europe, has rich yellow and deli-

ciously scented flowers. It is well worth cultivating, as it grows freely and gives little trouble, being perfectly hardy. Doubtless it would be excellent for naturalising on the fringes of shrubberies or in colonies on warm banks. It is also valuable for cutting.—Ed.

Godetias.—These appear to great advantage when pictured in seed catalogues and some speak well of them, but I am not able to do so, as I have found them amongst the worst of all annuals to be blenished by rain and wind; and this invariably rendered those we grow so unattractive, that I have ceased growing Godetias, and I have no intention of introducing them again.—J. MUIR.

Sweet-scented Polyanthus.—I find that the yellow Polyanthus, whether single or Hose-in-hose, are very sweet scented as compared with the dark coloured kinds, which curiously enough seem to lack perfume. This is very strange, especially as yellows often come from reds and reds from yellows where diverse colours are grown in contiguity. Still it would seem as if all yellow Polyanthus retained the Cowslip perfume, although it is hard to understand why perfumes should not be allied to dark colours. However, the matter needs more elucidating.—A. D.

ERYNGIUM AMETHYSTINUM OLIVERIANUM.

ONE of the very finest of our border plants and a type of a singularly beautiful class of vegetation, rigid and strong in structure, and yet of extreme grace and delicacy of detail; of wonder-

Amethyst Sea Holly (*Eryngium amethystinum* Oliverianum). Engraved for THE GARDEN from a photograph.

ful colouring that cannot be actually described, but that recalls impressions of many beautiful things; of polished silver and steel and moonlight, and fishes' scales, and the armour of archangels from the hands of the early Italian painters; a good plant to place singly or in groups apart from others, as the radical leaves are large and handsome and form a base of some importance—a necessary feature in a well-shaped plant or group. Happily, this good plant is so well known that to praise it is almost superfluous, but it may be well to remind any lovers of fine flowers who have overlooked it that they are neglecting one of the best ornaments of the garden.

ENCLOSED is a spray of *Laburnum*, to show how well it will force. The plant is in an 11 inch pot, and is bearing 135 sprays of its beautiful flowers. I also send flowers of Paul's

double crimson Thorn, the Guelder Rose, and *Cantua dependens*, which last flowers well in the cool conservatory here.—GEORGE SAGE, *Bilton Gardens, Grantham*.

* A beautiful gathering of flowers. The *Laburnum* was lovely, and from the specimens sent will repay any trouble that may be taken to force it. The other flowers sent were also fine, more especially the *Cantua dependens*, which was very bright.—Ed.

PROPAGATING.

AZALEAN.—Where Azaleas have been forced prematurely into bloom, and afterwards kept in a growing temperature, they will be by this time in full growth, and if it is desired to increase them, these young shoots afford a really means of doing so, as they strike root easily enough; or they may be grafted after the manner followed on the Continent, but still there is no reason why Azaleas should not be more frequently grown on their own roots, as most of the varieties will do well in this way, and may be grown into neat little bushes. In selecting shoots for cuttings, the very strongest should not be chosen, as, in common with most other subjects, the weaker ones strike root far more readily than the stoutest. In a general way, shoots such as are here mentioned will be about 4 inches or a little more in length, and if that is the case, the entire shoot should be taken to form the cutting. This will allow of the cutting having just a base of older wood, which is a great advantage. The bottom leaves must be removed with a very sharp knife, as, if this is not done, the bark is liable to be injured, and thus forms a seat of decay. Whatever sized pots are chosen, they must have a drainage of broken crocks to within 3 inches of the top, and then the soil must be pressed down very firmly, leaving just enough space at the top for a thin layer of pure sand. The soil for the purpose should consist of very sandy peat, sifted fine; and the size of the pots will depend upon circumstances, for the cuttings must be kept very close, and where there is no propagating house, they must be covered with bell-glasses. Such being the case, the size of the pots will depend upon the glasses that are available for covering them, but before the cuttings are dibbled in the soil should have a slight watering, when, if the glass is placed in position and pressed down, the imprint of the rim will serve as a good guide for the insertion of the cuttings, as they must be kept far enough away from the edge to prevent their being injured when the bell-glass is replaced. The pots should be placed in a structure of about the same temperature as that in which the shoots have grown, and should any bottom-heat be available they are better if stood on the surface for about a month, in order to allow the cuttings to callus, when if then plunged into a gentle bottom heat they soon root. Of course, during the time they are confined under glass they must receive careful attention in the matter of watering, &c., one very necessary item being the removal of the glasses every morning, in order to dry up any superabundant moisture, or to allow of the removal of any decaying leaves. This last precaution is very necessary, as should the least sign of decay make its appearance and not be quickly removed, it will rapidly spread and soon carry off a great quantity. The only insect pests to guard against are thrips, which are liable to effect a lodgment on the leaves if long confined, while if not removed they spread rapidly. Where grafting is carried out, any vigorous growing kinds may be employed as stocks, and to ensure success they must be young and free, as in that case the wounds made in the bark heal far more rapidly than in older wood. Side grafting is the method generally employed, as thus the head of the stock, or at all events a part of it, is allowed to remain on until a union is complete. In this way not only does the head of the stock assist in forming a complete union by maintaining a regular circulation of sap, but also should the graft fail, the same stock can be at once used again. The actual grafting is by no means a difficult matter, the great point of course being to see that the barks of stock and scion are joined as exactly as possible, and as the bark of

an Azalea is not very thick, more care will be needed in this respect than is requisite with some other plants. The usual method of side-grafting is to take the stock, and at the height needed an incision must be made in the stem, penetrating a little deeper than the bark. Then, about a couple of inches above this, commence to remove a piece of the stem, and continue this till the incision is reached. The scion having been prepared by making a sloping cut after the manner of that in the stock, the two must be fitted together as intimately as possible, and tied securely into position by means of some soft grafting cotton. Then they must be placed in an air-tight case where they soon commence to heal over, and when a union is complete they may be hardened off. The success of the operation will be shown by the scion commencing to grow, and when that is the case a little air may be given.

BOUYARDIAS.—One often hears complaints of non-success in striking cuttings of Bouvardias, but if they are taken now and formed entirely of the young succulent shoots they strike root readily enough. The cuttings should be put into light sandy soil and kept close till rooted, which will take place in about ten days or a fortnight. Root cuttings and those formed of the older wood have been recommended for the increase of Bouvardias, but the young shoots possess a great advantage over these, inasmuch as they root quicker and will form good, healthy little plants in less time than either of the above methods.

CLERODENDRONS.—The mention of root cuttings above suggests how easily most of the Clerodendrons can be increased in this way, and some of them grow very rapidly. *C. fragrans* and its double flowered variety, with *C. fallax*, are among the most commonly grown of the shrubby kinds, and if a few of the principal roots are taken, cut up into pieces about an inch or so long, and dibbled into pots of light soil, they quickly push forth fibres as well as young shoots when placed under favourable conditions. The climbing kinds do not grow with the same freedom from root cuttings, but as a set-off a greater number of young shoots are obtainable, and they quickly strike root. *C. trichotomum*, a hardy species which has of late years attracted a good deal of attention as a beautiful autumn-flowering shrub, is remarkably easy of increase from cuttings of the roots, so much so that having occasion to remove an established specimen I was surprised the following season to see young plants of this Clerodendron making their appearance on the spot where the large specimen originally stood. On examination these plants were found to proceed from pieces of the roots that were broken off during removal. Induced by this, I dibbled a painful of pieces of the roots, and the following season quite a thick crop of young plants resulted therefrom. The Chinese *C. lucidum*, a showy, but by no means common plant in gardens, can also be increased in the same manner. It matters but little at what time these root cuttings are taken, but in a general way the early months of the year are about the best, and where required but little time should now be lost if young plants are needed.

FORSYTHIA SUSPENSA is not a difficult subject to strike from cuttings, either put in the open ground during the autumn, or in summer protected by a frame. A simpler and equally effective plan is to peg down the points of the young growing shoots, and when brought in immediate contact with the earth they quickly strike, and soon form a base, from whence other shoots are pushed up in the same way as Brambles. These last can, of course, at times be increased by division, and seeds of some may be available, but cuttings taken in the ordinary way by no means root readily, yet every shoot will strike if its tip be brought in contact with the soil and held there securely. This mode of increase can often be seen exemplified in our hedgerows, but it is also equally available for the beautiful double-flowered forms that yield such a display during the summer. All the species of *Rubus* cannot be propa-

gated in this manner; indeed, the beautiful shrubby growing *R. deliciosus* is by no means an easy subject to strike from cuttings, nor a quick one when layered. I have derived the greatest measure of success from taking the young growing shoots in early summer, and putting them in a frame that is kept close and well shaded. A very distinct form of double Bramble is *rosa-folius plenus*, and this being generally treated as a pot plant, and grown in a fairly warm structure during the winter, will by this time have made plenty of young shoots, which strike root easily enough if taken off and treated in the same way as Fuchsias and similar subjects. As this kind is very liable to the attacks of red spider, care should be taken that the foliage is quite clean before putting the cuttings in a close case.

T.

FRUIT GARDEN.

W. COLEMAN.

WALL & HOUSE PEACHES.

If the short paragraph, most likely hurriedly written, by Mr. Gilbert was likely to influence the builders of fruit houses in general and Peach houses in particular, the cross fire from three heavy guns (p. 252) will induce them to ask a few questions before they step out of their well-chosen path. As no one knows better than Mr. Gilbert the value of glass, I think he would have corrected or qualified one sentence had time admitted of his seeing a proof before his article went to press. Such, however, does not appear to have been his good fortune, and he now stands pledged to his statements, unless, as I have no doubt he will, he finds a different interpretation. By all means let us have more wall Peaches, but not at the expense of a reduced supply from houses, for much as I value a few feet of sheet glass, I should be extremely sorry to see outdoor culture neglected. Like my three friends who have taken up the matter, I have devoted many years to the cultivation of Peaches against walls and in houses, and having been tolerably successful, am in a position to endorse much that each of them has said for and against the two systems. That house fruit invariably takes the eye of judges and the public I readily admit, but unless it is judiciously grown with an abundance of light and fresh air, I question if many dishes of wall Peaches are not quite equal, and sometimes superior, in point of flavour. The seasons for some years past having been unkind, wall culture has been carried on under many climatal difficulties, but, notwithstanding these drawbacks, I venture to think the fine trees of the past and the enormous fruit of our boyhood are altogether eclipsed by the trees and fruit of the present day. Peaches, it is true, do not realise the prices obtained twenty, nay ten, years ago, but then the slow and antiquated method of cutting away two-thirds of every shoot annually has been superseded by the extension system, and I question if wall or house within a given period from the time of planting does not now pay two nimble sixpences where formerly the heavy machine brought in a slow shilling. But enough, and lest I, like friend Gilbert, may be charged with preaching what I do not practise, I may say I am now converting a large, late span-roofed Hamburg vinery into a Peach house, and have recently transferred Apricots from a south to a west aspect to make more room for a set of late Peach trees. Further, without reflecting upon nurserymen who do not profess to hold fruit-bearing trees, the demand for these having greatly increased, I have just put up the finishing portion of a timber wall 200 feet in length, and 9 feet in height, for training pur-

poses. Upon these walls, composed of Oak framework and deal boards, facing the west, Peach and Nectarine trees under my system of management always ripen their wood well, and when allowed to remain, ripen their fruit from fourteen to twenty-one days later than kindred kinds on brick walls facing full south. Mid-season sorts on south walls in good seasons produce a glut, and this, combined with the immense quantity of late house Peaches, keeps the price down. But still they pay better than Grapes, and on our cold, heavy soil they are more certain than Pears. I recollect reading in THE GARDEN a few months ago a statement from Mr. Gilbert to the effect that he had rushed up young trees of Walburton and the old Late Admirable, but was disappointed with the result. I, perhaps presumptuously, ventured to suggest annual root-shortening and more water, and, judging from the fact that he is now "going in for more wall Peaches which nobody seems to grow," conclude he has brought the first set of trees into subjection. The climate at Burghley is perhaps not so good as ours, but here, being surrounded by heavily-wooded limestone hills, the atmosphere is moist and cold—so cold, that my predecessor told me I had better not attempt the growth of wall Peaches. He, good man, having gone over to the majority, his system has gone too; but, regardless of his advice, I at once set about correcting defects then existing, below as well as above the surface, with the view to replanting the walls. The first operation was thorough draining; then, having the command of several hundred loads of old lime and brick rubble and the run of the top spit of a new line of railway, materials for a fresh start were speedily in readiness. When the old borders, richly endowed with rotten manure, were taken out, a concrete bottom, strong enough to carry a castle, was found 3 feet below the surface. As it was not my intention to allow the roots of the trees to penetrate the drainage, much more to touch the concrete—in this case quite an unnecessary expense—12 inches of rubble, 6 feet in width, completed the bottoming of the borders. Upon this, thin sods of turf, Grass side downward, were laid, and the compost, consisting of pure loam and old lime rubble, was wheeled in. Bone-dust in quantity to be of any use, had I thought it necessary, was a luxury beyond my reach, but this, much as I value crushed bones, mattered little, as stone fruits grow well, and the roots literally devour every bit of turf in the absence of its coaxing, stay-at-home allurements. Knowing that all the trees would require lifting at the end of the first, certainly the second, year, all my borders, in the first instance, were made 3 feet in width and a little over 2 feet in depth, not one particle of manure being admitted. To each tree a run of 24 feet was allowed, a duplicate being introduced for future removal. The winter of 1860-61 having destroyed thousands of young Peaches and Nectarines, some of the sorts supplied to me, obtained from France, did not prove true to name. Peaches in some cases turned out to be Nectarines, and *vice versa*; but all showed a disposition to grow, and by the judicious pinching of gross shoots they soon reached the top of the wall, which was too low. At the end of the second summer all the trees were lifted bodily and re-arranged with their roots lying in a horizontal position, and I can safely say from that time to this I have never missed having a full crop of wall Peaches. "J. S. W." is quite correct in saying that wall Peaches entail an immense amount of trouble, but then whatever is worth doing at all is worth doing well; therefore, whilst agreeing with Mr. Gilbert that more wall trees should be planted, I think house

culture, in which English gardeners excel, may safely be left to take care of itself.

MELONS, OLD AND NEW.

I NOTE what "J. C. C." says on this matter (p. 232), and remember his two favourite sorts well—the Beechwood and the Egyptian Green Flesh, both Melons possessing the highest flavour. The Beechwood, however, not seldom lost its foliage in the latter stages, like a good many Melons of the present day, and such well-known modern Melons as Read's Scarlet Flesh, Victory of Bristol, and Best of All are just as hardy in constitution, and perhaps more easily grown than the Beechwood and Egyptian Green Flesh; in fact, the two latter were always considered more delicate and difficult to grow than the coarser Rock and other Melons that were often preferred to these two, because they were more easily grown. I believe that more frequent breakdowns in modern Melon growing arise less from differences of constitution in the varieties cultivated than in changes in the modes of culture between the two periods. Whatever merits or demerits the old system of growing Melons on manure beds in pits or frames possessed or lacked, it was more favourable to the stability and longevity of the plants and the preservation of their leaves than our present modern methods. We met our difficulties and dangers in the beginning in pits and frames; but we have too often to encounter them towards the end of our culture in Melon houses. With a fair amount of soil and an inexhaustible store of manure under it the difficulty was rather to arrest growth and check the production of green leaves as the maturation of the fruit approached. With the scant supplies of soil allowed to Melons in modern houses, nothing is more probable than the exhaustion of the plants and the scalding or withering of the leaves as the fruit reaches maturity. Nor is this premature exhaustion of the plants wholly the result of their short supplies. The pace is intensely accelerated in modern as contrasted with old-fashioned Melon growing. One good crop a year in one pit or frame was considered quite satisfactory. Now, two, three, or even four crops from one house in the season are not considered anything extraordinary, and in Melon growing, as in racing or working, it is the speed that kills. Modern Melons are also sadly over-cropped as contrasted with those of olden times. It is no uncommon thing now to find the roofs of Melon houses studded with Melons almost touching each other. All advance well, and under powerful stimulus swell rapidly until the strain comes towards the finish, then the mechanical weight of the fruit, as well as their scramble for the materials and conditions of perfect maturity, starve and cripple and cut off the supplies from the leaves, which perish and the fruit suffers in flavour in consequence.

HORTUS.

Grafting and inarching Vines.—Mr. Coleman's remarks on this subject in THE GARDEN (p. 113) are excellent. With bottle grafting I have been very successful, and this is my favourite method. Let me assure Mr. Coleman that some Gros Colmars grafted on Muscats three years ago not only made good rods 20 feet long the same season, but have so united that I have to look twice in order to make sure which are grafts and which stocks. The operation being new to me, I was not content with trying what I supposed to be the right plan, namely, inarching with pieces to match the laterals left for the purpose, but I also laid several pieces on old stems or rods, and to my surprise these latter united as well as the others. In inarching on the old wood I was careful to at least see that one side of the scion was bark to bark. These old wood scions grew and are doing well, but they have not the strength that those have which are treated in the usual way. I think the cause of this is that, whereas I cut through at least one eye in both stock and scion (from which eye the union first takes place), in old wood inarching no eye or joint is to be had. In order to have the scions moving to correspond with the stock I keep them at the warm end of the house, and if I think they are not quite forward enough I lay them in warm water. I may add that in no case have I had to cut the old canes down. Did I have to do so I should object on the score of

losing the crop. Generally, but not always, I cut down at pruning time after the crop is cut. In some cases I have both stock and scion growing and fruiting side by side, and thus have Muscat and Gros Colmar, or Buckland and Alicante, or Gros Maroc, all bearing fruit at one time, the mixture when ripe having a somewhat diversified appearance.—STEPHEN CASTLE.

AMERICAN BLACKBERRIES.

THE character given in THE GARDEN (p. 232) by "J. C. C." to the American Cut-leaved Blackberry is so entirely contrary to our experience of this plant, that I cannot pass it without comment. "Any growth worth notice" is a trifle vague, but it does not give the impression of a plant that makes immense shoots 20 feet in length, which are wreathed with fruit throughout late autumn and affords us one of our most valuable crops of small fruit. During the last four or five years the fruit of this handsome plant has steadily increased in favour for use in preserves, tarts, and even for dessert—so much so, that recently wherever the native Bramble has been found growing about the place, it has been stubbed up and replaced by the American. Everyone knows the want of briskness in flavour and somewhat over-sweetness that have been so often urged as an objection against the native Blackberries when cooked, and which involve the addition of a sharp Apple or so to "wake up" a tart made of their fruit; but no such objection can be made to the fruit of the Cut-leaved Bramble, which maintains its brisk flavour when cooked and makes a delicious tart without any addition. When preserved also the flavour is far brighter and more piquant than that of the common Blackberry, and some persons even prefer the American Blackberry jelly to Red Currant jelly with saddle of mutton, &c.

The plant grows luxuriantly with us in any soil, sandy or heavy, but the best results have been obtained by planting in strong, well-manured land. Here the plants are grown beside a wire fence about 10 feet high, and treated just like gigantic Raspberry canes, the wood that has fruited being cut away and the immense young rods tied back more or less fan-shape to carry fruit for the season. It is not recommended for the north of England except as an ornamental plant, because in wet or cold localities the fruit being produced late does not get properly ripened. But in the south, even as a dessert fruit, it is superior when thoroughly ripe to the native Blackberry; only care must be taken to see that it is ripe, for the fruit colours early, and is therefore often picked because it is black, and if its flavour be then judged it may not of course be first-rate. When the fruit is quite ripe it does not require pulling, but comes off at a touch, and in that condition its flavour is excellent, and the fruit long of berry and large of pip.

As an excuse for standing about in fields and hedges on a sunny October day the wild Bramble has great attractions; but for tarts and preserves of delicious flavour the American Cut-leaved Blackberry is unrivalled and unapproached by any species native to this country.—T. W. G.

"J. C. C." states (p. 232) that these are a failure with him. His experience is exactly the same as ours. They absolutely refuse to grow, though the common Bramble is very much at home within sight of the American varieties. I must correct the last phrase, for the Americans have almost disappeared out of sight of their English relatives, though careful attempts have been made to grow them. Locality can hardly be the cause of failure, for the whole of East Anglia is proverbial for the luxuriance and fertility of its English Brambles in hedgerow and wood, as well as also frequently in shrubberies.—HORTUS.

Dessert Apples.—I herewith send you four dishes of dessert Apples. Having seen of late various opinions in your valuable weekly paper THE GARDEN respecting late keeping dessert Apples, as also America *versus* English as to colour and flavour, I was induced to send these as a sample of what we

grow in these gardens. They are from bush trees not more than 5 feet high. The trees bear crops every year, although this is not a good soil for Apple growing, as it is so light and dries up so quickly that the fruit is small.—JOHN CROOK, *Farnborough Grange, Hants.*

* * * Good samples of Cox's Orange Pippin, Sturmer Pippin, Ribston Pippin, and Lord Burghley. They were in very good condition, but lacked that sharpness which is to be found in these varieties when they are in season. What we want is a late Apple that will retain its briskness up to this time.—ED.

TRANSPLANTING VINES.

OPINIONS vary as to the best season for lifting and replanting the Vine, some preferring carrying out this important operation in the autumn, others during the winter while yet the Vines are dormant, and still more when the buds are bursting in the spring. If a renovation of the border only is contemplated, I should prefer to do the work in the autumn, or, say, late in September or early in October, at which time the leaves would be quite fresh and in good working order. Supposing the principal portion of the border was broken up, the roots being carefully preserved and relaid in a good fresh compost, not necessarily all turf, abundance of fresh fibre would be formed long before the leaves ceased to perform their functions, and the following season the Vines would be capable of carrying comparatively heavy crops of fruit. I repeat comparatively heavy crops, as it is owing to working renovated Vines too hard the first season that many besides myself have erred. Finding that they break strongly and appear to be well established in the fresh border, cultivators are tempted to retain as many, or nearly as many, bunches as are usually perfected by healthy Vines that have not been subjected to such a severe trial. The effect of this is not so much perceptible the same season as during those following when it will be found that the Vines have experienced a check from which they may not quickly recover. Instead of the whole of the Vines' energies being expended upon the production of a full crop of bunches, part of it ought to be diverted to the formation of abundance of fibrous roots and their usual accompaniment—well ripened wood growth. It will then be eventually found that a new and perhaps expensive border has been made for some purpose. Unless the work of renovation is carried out in a thorough manner, the improvement effected in the Vines will only be fleeting, and I have seen instances where it would have been a wiser plan to clear out the house entirely and start with a new border and Vines. As was pointed out on page 232 the best time to lift the latest Vines, or those which of necessity have to carry their crops till late in the winter, is at the present time. The work of partially lifting may yet be safely done, and if from a third to one-half of the border be undisturbed, the roots found in the portion forked away, preserved as much as possible and redistributed throughout the fresh compost, it will not be long before these are as active as could be wished for. The foregoing refers principally to the partial lifting of Vines.

WHOLLY LIFTING AND REPLANTING.—If it is thought necessary or advisable to completely lift Vines and transfer to another site, much the safest and best time to do it is just as the buds are on the point of bursting. Authorities upon the Grape Vine are generally of opinion that the roots do not commence active growth till the leaves are far advanced or about three parts developed, in this respect materially differing from the majority of deciduous trees. This may be true enough in the case of Vines that have been started at all early or which are rooting in a cold outside border; but the theory does not always hold good with regard to those rooting in an inside border, and which are allowed to start naturally. According to my experience, these frequently commence forming fresh fibres almost simultaneous with the bursting of the buds. For three years in succession we have had occasion to lift Vines during March, the buds being on the move in each instance, as were also many of the roots. When the transplanting is attempted while the Vines are in a dormant state, there is a possibility of many of the fibres rotting in the fresh soil, every wound being a long time in heal-

ng, and the consequence is a very weakly and uneven break. I find that both very old or quite young Vines may be wholly lifted and replanted in March without the total loss of crop. In 1883 we lifted ten large Vines of the Black Hamburg variety none less than fifteen years old, and brought them a distance of three miles, replanted them in a new house, and cropped the majority the same season. All had been previously rooting in a much-neglected border, and it was at one end where a pathway had been made where the failures came from, very few roots being obtainable with these. The bunches perfected on these transplanted Vines were small, but the berries swelled to a good size and finished well, so that on an average 6 lbs. of Grapes were obtained from each. They were planted as supernumeraries, and have since formed good stocks for late varieties. In the same house another row of supernumeraries was planted through the centre of the house. These perfected two crops, and the best of them were then given away. They were carefully lifted just as the buds were moving, and transferred to ainery two miles distant. Anything in the shape of a ball of soil about the roots is out of the question in transplanting Vines, but we took special pains in preserving as many roots as possible, and carefully protected these from cold drying winds. They were planted in an inside border, and the same season several of them perfected three good-sized bunches, the best weighing nearly 2 lbs. In addition they formed good rods, and last season from one of these was cut a bunch of Alicante weighing 3 lbs. Newly lifted Vines when in full leaf may perhaps flag badly on a sunny day, and until the roots are able to meet the demand on them, it is advisable to syringe a little thin lime-wash over the roof. Wholly or partially lifted Vines must have plenty of water supplied them, neglect in this respect soon telling its tale. Like plants in pots, they are dependent upon the supply of water from the surface, where undisturbed Vines ramble about in search of moisture. These sometimes sustain the crop when the principal portion of roots may be much in want of moisture.

YOUNG VINES are largely planted at this time of year, and rightly so, I think. They are supplied in pots by nurserymen, or raised on the place during the previous season and grown in pots. To plant the balls of roots and soil intact would be a mistake, and instead of this they ought to be soaked in a pail or tub of water, thus facilitating the separation of the soil from the roots, which admits of their being carefully untwined and spread well out into the soil. Thus treated the roots soon take possession of the soil, and from first to last the chances are they will do better than any that may be planted intact. As a rule these young Vines should be made to form a fresh rod from near the ground. To prune them now would most probably be followed by excessive bleeding, and in order to avoid this it is advisable to give the rods a sharp curve, thus inducing a strong break from the lower joints and, to further strengthen those to be laid in, all the upper buds should be rubbed out as fast as they burst. In many instances it is necessary to plant rather stronger rods than are usually supplied for the purpose, this being especially the case when they have to be brought through from an outside border. These should also be encouraged to push out their lower buds, and if the laterals resulting are stopped when at the fourth or fifth joint, these will help to swell the stems. Unless the stems are assisted to swell in proportion to the principal rods, sooner or later a check will be given, and a falling off in the value of the crops experienced. These tiny planting canes, with not a shoot on them within 2 feet or 3 feet of the ground, as we often see them, are very slow indeed in attaining a profitable size. I always prefer to plant inside, even if the principal portion of the roots is soon established in the outside border, and in this case quite the smallest canes are to be preferred—a very rank start not being desirable. No doubt the compost recommended by Mr. Coleman is most suitable for a border that is to be serviceable for a considerable time, but plenty of turf is a luxury few of us attain to. Luckily, it is quite possible to grow good Grapes for many years in a border composed principally of turfy loam and good garden soil in equal portions, lime rubbish, burnt garden refuse,

wood ashes, and bones being freely added. The best of Vine borders soon requires renovation.

I should add that a high temperature ought not to be kept in a house containing newly-planted Vines, especially when these have experienced such rough treatment as just described, the aim being to keep them slowly growing until the roots are active. A night temperature of from 50° to 60° is ample, and in the daytime it may vary from 60° to 70° with plenty of moisture about the house. Better, however, let the thermometer range rather higher than to subject the Vines to cold currents of air, which cause them to flag badly. W. I.

A curious Apricot tree.—We have here a large Apricot tree presenting a very singular appearance. It is on a south wall at the west end of a range of vineries. The east end of the tree is now covered with fruit and foliage. The tree from top to bottom, for about 2 feet wide, is covered with fruit as large as small Hazel Nuts. The middle of the tree is in full bloom, and the other half, or west end, is not yet in flower. The cause is a chimney-flue, which runs up at the east end and keeps the wall constantly warm. The tree is protected by a coping 18 inches wide, and a double thickness of common herring-net in front. The tree ripens its fruit in the same order.—ALBERT FENN, *Blythburgh Gardens, East Dereham.*

Protecting fruit trees.—Unless we get exceptionally severe weather in April, the chances seem favourable to a capital crop of nearly all fruits, and it is quite time to see to protecting materials, and to keep generally a watchful eye on the fruit walls and quarters. Of all different materials used for spring protection, I do not know of anything better than the ordinary 1-inch mesh fish-netting. Where fruit walls are naturally sheltered a double thickness is generally sufficient; but, on the contrary, where they are much exposed, it is advisable to put a triple thickness of net, and this I have only known to fail once, viz. in the very sharp frost of April, 1884. The netting is, I think, preferable to heavier coverings, such as tiffany, &c.; for, whilst breaking the force of all keen, biting winds and heavy sleet or hail, it allows plenty of air to play amongst the trees. Before the nets are put up, the trees and wall should have a heavy syringing to dislodge as much as possible any insect life that may be already on the move. Where red spider is prevalent, a sharp watch should be kept at this season on all kinds of bush as well as wall fruit. We were nearly caught napping last year with the Red Currants and Gooseberries, for the pest was getting a firm hold just as the buds were expanding, and had the trees not received two or three good washings they would have been nearly ruined for the season.—E. B.

SHORT NOTES.—FRUIT.

Is spur pruning out of the question when a Peach tree in good health refuses to bear a fair crop, root-pruning having been tried? The tree is an early Grosse Mignonne. Is this a specially difficult tree to fruit?—X.

MR. STEPHEN CASTLE, of West Lynn, Norfolk, has sent us a fine photograph of a wonderful house of Early Downes Grapes, of which we hope to have the pleasure of engraving a portion in good time.

The wild Plum of Japan.—Can any readers of THE GARDEN tell me where to obtain *Prunus pseudo-Cerasus*, the wild Plum of Japan, and what synonym it has, if any? The Japs call it "Sakuta."—FRANK MILLS.

Apricot bloom.—It would doubtless be difficult to ascertain the mean average when the earliest Apricot blooms on south walls expand every year. It is odd, however, that here, whilst in a very warm aspect due south and protected by a broad eave, the bloom is only just expanding, yet it should be reported as open a week earlier in the south of Scotland.—A. D.

Grafting seedling Oranges.—Will you kindly inform me in your next number when is the time to graft seedling Orange trees, and how it is best done so as to bring them into flower and fruit?—JOHN GREEN.

The present month is the best time to graft Oranges; the stock used should be the bitter or Seville Orange. Whip-grafting would be practised. Pot culture and a moderate heat will bring grafted plants of the cultivated sorts into bearing during the fourth year from grafting. Seedling Oranges may bear in ten or twelve years under the same conditions of cultivation.—T. F. R.

SEASONABLE WORK AMONG FRUITS.

(CHERRIES.)

ALTHOUGH two thirds of the month of March was wintry in the extreme and much snow fell, the weather, on the whole, has not been unfavourable to forcing operations. Much fuel, as a matter of necessity, has been consumed, and low night temperatures in every department have prevailed, but beyond the loss of a little time a fair average of bright sunlight has favoured the healthy growth of leaf and fruit. Cherries with us, thanks to well-ripened wood, have been a sheet of the finest bloom imaginable, and, judging from present appearances, the scissors will have to be freely used as soon as we have disposed of our first enemy, the active little grub, whose appearance at this stage is more certain than agreeable. If carefully fumigated before the flowers open, they can generally be kept in subjection until the fruit is set; but it is necessary to be ever on the watch, and whenever a single insect puts in an appearance a series of mild smokings may be commenced immediately after the petals drop. One smoking, however, generally settles the account with green aphids, and as daily syringing will now be safe and necessary, a dash of Quassia or soot water mixed with the ordinary soft water will most likely maintain a clean bill of health throughout the season. The house having been kept comparatively dry during the time the trees were in flower, the borders will now be in a fit state for a liberal supply of tepid water, which may be tinged with good liquid or not according to the condition of the soil and the age of the trees. It is usual to mulch old trees which fruit heavily every year and do not produce much wood, sometimes before the house is started, in all cases immediately after the Cherries begin to swell. Young ones, on the other hand, do not require it, as manure often produces a gross habit of growth before they feel the weight of the crop, when, independently of the trouble they give, the rapid rush of sap frequently causes them to cast their fruit before it reaches the critical stage of stoning. With these hints the young forcer of Cherries must shape his own course, as it is impossible to say without seeing them what regimen will best suit his trees. One thing, however, is certain; it is always safe practice to err on the side of temperance through the earliest stages of forcing, and, whilst giving plenty of water to the roots, make them ramify and work for their daily supply of food.

Ventilation.—Highly impatient of a high temperature, the Cherry must have a liberal supply of air, not only by day, but throughout the night whenever this element can be admitted without creating a draught. When one says the house must range from the low figures of 45° to 50° through the night and 50° to 60° by day, it may be assumed that a temperature so little above that of the external air can be maintained by opening the ventilators in the morning and closing them in the afternoon. But this method will no more suit Cherries than it suits Pines, Vines, or any other forced fruit. Whatever the range, be it high or low, the start must be made from the minimum point; fluctuations must be avoided until the maximum is reached. The descent by reducing must then be prevented, and finally a rise of a very few degrees in the Cherry house may take place after closing with sun heat and moisture. It is during this period of confinement, extending over three or four hours, that the most progress is made, and when this end has been attained, the chink of night air with a gentle circulation created by the hot-water pipes must regulate the temperature through the hours of darkness. If properly managed and sudden external changes do not take place, the lowest point will be touched about daybreak the following morning. Night air must then be shut off and the trees duly syringed, but not until the temperature begins to rise, when the method adopted on the preceding day must be repeated.

THE ORCHARD HOUSE.

If good progress has been made, the fruit in the early forcing house will now be stoning, and, as I

have often observed, making but little apparent progress. Good work is, however, going on, and when the formation of the stones is complete, a process which, by the way, should not be hurried, there will be a rapid move forward. When this takes place, not a day must be lost in making the final thinning, as every fruit that starts away freely under ordinary treatment may be considered safe, whilst those which do not move may at once be pulled off to save them from falling. Many amateurs who dictate to their gardeners are often, I am sorry to say, guilty of over-cropping, but if quality be the object, the practical man in the performance of this important operation should not be interfered with. When the crop is properly reduced, robust trees will require daily attention to regulating and stopping, not only to prevent waste of force, but also to keep them compact and evenly balanced. Commencing at the highest part of the tree, pinching to six or eight leaves on each strong shoot should be steadily continued downwards. All the shoots must not, however, be so treated, as many, especially those near the base, will not make more than a few inches of growth, and when it is borne in mind that these only produce two wood buds, one at the base, another at the point, the removal of the latter, it is hardly necessary to say, renders them useless.

Top-dressing.—If all the trees were well top-dressed as soon as the fruit was thinned and the surface-roots have taken full possession of the material, further supplies will now be needful. Indeed, a good store of rich, heavy loam, old manure, and bone-dust should be kept constantly on hand for use whenever the feeders show upon the surface. In order to secure room for these repeated applications, the balls should be kept well below the rims when the trees are potted in the autumn, but old ones which cannot be so treated must be managed differently. To these I apply bands of old sheet lead 3 inches or 4 inches in width, which fit tightly inside the rims, and at once make room for the top-dressing, likewise for the quick supply of water. Strips of zinc answer equally well, and, with care, last a lifetime; but when large, old trees get beyond 16-inch pots, I prefer tubbing and reducing the balls annually. Fortunately, under this system there is no fleeting limit to age, as I now have trees wearing out their second set of Oak tubs, and the fruit they produce is equal to the best I gather from ordinary Peach houses.

Water.—From the foregoing remarks readers will gather that I set great value upon top-dressing, but this is of no use where the trees are stinted for water. When plunged out of doors during the winter, pot trees do not require frequent attention, but when taken into the house the soil must be kept constantly moist by the judicious use of pure water. When the fruit is set and swelling, stimulants, always on the weak side, may be used at every watering. Good diluted drainage from decaying manure and guano water used alternately supply all the elements needful to the formation of wood and fruit, and answer better than the constant application of one stimulant only. Each tree should be examined every day, and whenever water is needed, sufficient to moisten every particle of soil must be given, otherwise the surface will appear moist, whilst the crotch roots are languishing. The same is also suitable for damping down the house and filling the evaporating pans: but pure, soft water, free from lime, should always be used for syringing, as it does not leave a deposit on the woolly coats of the Peaches. This operation must now be vigorously performed twice a day, the first time when the temperature begins to rise, the second when the house is closed for the afternoon swelling.

Ventilation for the present should be very carefully managed, for much as the Peach enjoys fresh air, cutting draughts must be avoided. Before orchard houses became an institution it was not unusual to find pot trees swelling off crops of fruit in Pine stoves and vineries, but the less said about

the quality the better. Colour and flavour are now sought, and the two generally not always run together. In Peach houses proper we aim at 55° to 60° on mild nights after the fruit is stoned, and 70° to 75° by day, with a circulation of air. In the orchard house, especially where the roots have the benefit of the slightest bottom-heat, a trifle more will do no harm on bright, sunny days, but 60°, with the usual chink, should never be exceeded through the night.

Mixed collections of Peaches, Plums, Cherries, and Pears in late houses will now be in full flower. Formerly it was the practice to keep these structures very dry, and to allow sharp currents of air to rush through them, but then many of these were minus the benefit of gentle fire-heat so essential to a sure set in damp, foggy weather. Now we can sustain the delicate organs of fructification by the use of moisture on bright, sunny days, as the flow-and-return pipes enable us to set sharp morning frosts at defiance. The proper temperature for these miscellaneous collections is 40° to 45° through the night, 50° to 55° on dull days, and 60° to 65° with sun heat. Fertilisation after this date is not an absolute necessity, as the hive bees are excellent allies, but the operation takes up very little time, and if it be true that cross-fertilisation increases the size and safety of the fruit, the application of the brush on fine days should not be neglected. If well fumigated before the trees came into flower, aphids, to which Plums, Cherries, and Strawberries are so subject, will hardly put in an appearance; if it does, the new system of steaming, so highly recommended, might be tried on a small scale, as we are told the most delicate flowers pass through the process uninjured.

PINES.

If the potting of successions and young stock generally has not been brought to a close, this work should now be finished without delay. Formerly, when Pines were grown in quantity we always made an effort to get all the beds renovated and rearranged before the thinning of Grapes and other spring work became pressing. This, at the present time, is of less consequence, as, practically speaking, the English Pine grower's occupation is gone. Still, we have a remnant left, and that remnant, be it only a score of plants, should receive proper attention.

Fruiting plants.—These should have two neat sticks placed in each pot to keep the fruit and crowns in a perpendicular position as soon as they are out of flower. All gills, too, should be rubbed out and suckers of Queens, if not wanted, reduced to one, or at most two, on each stool. Some growers make a point of plunging their plants after the fruit is up as close as they can be placed together, but the system has little to recommend it, a few more fruits perhaps may struggle upwards, but to my eye they look very uncomfortable, and I always think the growers should be punished for cruelty to the suckers. Glass now is cheap enough, and Pines are good in proportion to the breadth of foliage exposed to air and sunlight. Late winter fruiting plants, now full size, may be plunged in this way, as time only is needed to finish them off. Moreover, their space may be required for fresh batches of spring starters or successions. As the season advances light dewing overhead may be more frequent, provided it can be done without wetting any of the fruits that are in flower, and each plant will take more water of a generous nature at the root. Indiscriminate watering will not, however, do; therefore each plant must be carefully examined and liberally supplied with diluted liquid or guano water when the roots actually require it. The watering of Pines is a matter which requires great tact and judgment, as we find them in some soils filling the pots with a mass of white roots, whilst in others they make very few. The first, as a natural consequence, take copious supplies with impunity, but the second take very little, and that principally in an atmospheric form when they are swelling off their fruit. Early maturity being important, the bottom heat in this department may now range from 85°

to 90°; the top heat 70° by night, 80° to 85° on fine days, and 90° after closing with vapour. In very bright or fiery-roofed houses, a little light shade from 11 to 1 o'clock may be necessary, but with plenty of roots beneath them the less shade the better.

Succession houses.—The beds in these should now be examined, and if hard spring firing has not made them too hot or too dry, the leaves or tan may now be levelled down and pressed firmly about the pots. If the material is found dry, then a good soaking round the outer edges of the pots will restore moist fermentation and reduce the necessity for frequent root-watering. Maintain a growing atmosphere in all succession pits by damping every available space twice a day and give the plants a light dewing overhead after the pits are closed. The greatest danger at this early season is getting newly-potted plants too wet at the root, and the better to avoid this, the dewing of which I am now writing should not be so heavy as to charge the axils of the leaves to overflowing. When this overflowing is frequently repeated the soil about the collars of the plants becomes sour and pasty, and free varieties throw up a profusion of premature suckers. A bottom-heat of about 85° from fermenting leaves will favour the rapid formation of roots and greatly assist in keeping up the air temperature, which may range from 60° to 65° through the night and 75° to 80° by day. A little air should be given at 70°, not to lower, but to sweeten the atmosphere, and gradually increased as the temperature rises until it touches 80°. When the sun begins to lose its upholding power the pit should be closed and allowed to run up to 85° or 90°. If late suckers have not yet filled their pots with roots they should be shaken out and repotted in fresh compost. Newly detached suckers may also be potted and plunged with them, as the two sets will require similar treatment. If plunged in a sharp bottom-heat obtained from fermenting leaves they root quickly without the aid of much water, and thoroughly enjoy the humid atmosphere of a close shallow pit, which does not require shading.

W. C.

GARDEN FLORA.

PLATE 590.

THE OLYMPIAN ST. JOHN'S-WORT.

(HYPERICUM OLYMPIOUM.*)

We have already given in THE GARDEN coloured plates of three of the shrubby St. John's-worts, viz., *H. triflorum*, *H. Hookerianum*, and *H. patulum*, which are unquestionably the finest of the larger growing species, while *H. olympicum* herewith figured has no rival among the dwarfier kinds. It is indeed a showy and most valuable garden plant, and it is singular that it is so little known in gardens, and this is the more remarkable because of its being one of the oldest among cultivated plants, having been introduced so long ago as 1706.

H. OLYMPIOUM is of dwarf growth, its usual height being about a foot, and is at once known from all the other St. John's-worts by its very glaucous foliage and large flowers—about 3 in. across, of the brightest yellow, and produced in summer. It is spreading in habit and a rapid grower; a cutting soon makes a dense tuft a foot or more across. Being perfectly hardy and indifferent as to soil, its value as a border or rock garden plant can scarcely be over-rated. It succeeds best on light warm soils, and especially if well drained, as rock gardens usually are. It is not such a shrubby species as *H. oblongifolium* and *patulum*, but more so than the common *H. calycinum*, or Rose of Sharon. It is a native of Mount Olympus, and is among

* Drawn for THE GARDEN by Miss Low at Woodcote, August 15, 1886, and printed by G. Severeus.

HYPERICUM CYMOSUM

the first 2000 plants figured in the *Botanical Magazine*.

A selection of the finest St. John's-worts for general cultivation would include, besides olympicum, the following shrubby species: *H. Hookerianum* (also called *oblongifolium*), the most beautiful of all the shrubby kinds, having large cup-shaped flowers of a deep rich yellow produced in clusters at the ends of shoots a yard or more in height. It is perfectly hardy, and flowers continuously in late summer. It is a native of Nepal, where it forms a bush from 6 feet to 8 feet high. Another species from the same region, *H. uradum*, is showy, but the flowers are much smaller, and the growth is more slender and not so tall. *H. patulum*, a native of Japan, is scarcely inferior to *Hookerianum*. The flowers are smaller, but of the same rich yellow, and produced in large clusters on slender shoots during September and October. It is not an old introduction, having been brought to this country about twenty years ago, though Thunberg, the great Japanese botanist, discovered it a century ago. Its growth in this

Flowers of *Hypericum Hookerianum* (*oblongifolium*); full size.

country varies from 2 feet to 3 feet high, according to locality, but in Japan it grows considerably taller. *H. nepalense* is a graceful little plant of slender growth, bearing cup-shaped flowers about an inch across, but it is not so desirable as those previously named, though we should include it in a selection, as it is so hardy.

All the foregoing are shrubby plants, natives of the East, and it is remarkable that though there are several species natives of America, not one of them can be called a really good garden plant. There are *H. Kalmianum*, *prolificum*, *virginianum*, and *pyramidatum*, but these are only fit for planting as undergrowth in rough places. There are several European species, but only one of them, the invaluable *H. clycinum* (the Rose of Sharon) can be called a first-rate garden plant, and indeed this vigorous, creeping under-shrub is worth more than all the rest of the dwarf St. John's-worts, seeing how indispensable it is for clothing with beautiful evergreen growth dry banks and other spots where it would be folly to plant anything else.

But there is no need to dilate upon the value of such a well-known plant as the Rose of Sharon. The Olympian St. John's-wort is somewhat similar in habit, and we should like to see it clothing sunny banks, like as the Rose of Sharon delights to spread over a shady bank.

There are a few other neat little evergreen St. John's-worts natives of Europe, but these are scarcely to be recommended for general culture, as their hardiness is questionable. Among these are *H. balearicum*, *egyptiacum*, *Coris*, and *orientale*. All are pretty plants, and particularly interesting to those who give personal attention to their rock gardens. W. G.

STOVE AND GREENHOUSE.

T. BAINES.

CHOROZEMAS.

For elegance in habit of growth, combined with the brilliant colours of their flowers, several of the *Chorozemas* stand unsurpassed. These plants bloom freely, the flowers opening in succession so that they keep up a gay appearance for a length of time. Neither are the different kinds difficult subjects to deal with, as with reasonable attention they are not liable to die or get out of condition. That these and numbers of other distinct and beautiful hard-wooded plants are not more generally met with in greenhouses and conservatories is more than likely due to the insensate cry that has been raised against trained plants. The same plants when only required for home use need no more ties than will just support them and prevent their branches assuming the straggling, half-procumbent position which in a state of nature they take. As many sticks as would suffice for an ordinary well-grown *Pelargonium* will be enough for any of the kinds of *Chorozema* when the plants have not to be moved further than from the house where they are grown to another in which they may be required whilst in bloom. There is so much difference in the character of growth natural to the different sorts of *Chorozema*, that some may be used as climbers, whilst others are dwarf and bushy,

not often attaining a height of more than 3 feet; still, they may all be grown bush-shaped by attention to stopping the shoots. There is also much difference in the rate of growth in the various species and varieties and in the size they attain, such kinds as *C. Henchmanni* and *C. varium nanum* not often reaching more than 2 feet or 3 feet in height, by as much in diameter. Like other Pea-blossomed genera, the *Chorozemas* are not open to the objection sometimes raised against plants with flowers of a more formal shape. The *Chorozemas* are so nearly allied to *Mirbelias*, *Podolobiums*, and *Dillwynias*, that some of the species of each have frequently been ascribed to the others.

Much of the distinct appearance which the plants under notice have is owing to the marked difference in the character of their foliage from that of other hard-wooded greenhouse subjects. In most of the kinds usually met with in cultivation the leaves are large and are furnished with spines like a Holly, so that even when out of bloom the plants are interesting. The time of flowering of the different sorts to some extent

depends on the way they are treated in the matter of warmth. *Chorozemas* are not subject to mildew, like some greenhouse plants, if kept during winter with no more warmth than necessary to preserve them from frost, but it is not well to keep them in so low a temperature as this for any length of time, as if under such conditions the soil happens to get a little too wet the roots are liable to perish, which means death to the plants. Unless there is some special object in retarding the flowering when they are wanted for ordinary decorative use, it is better to keep the plants at 40° or a little over in the night through the winter, in which case they will begin to open their flowers early in spring, at which time before many of the spring blooming subjects come in they are very serviceable, and when kept a little warm the flowers are much larger and more brilliant in colour. They keep on blooming for several weeks.

The taller growing kinds are very effective when trained round a pillar in a greenhouse or conservatory, or attached to wires fixed to the side or end lights of the house; but when so used it is not advisable to plant them out in a border in the way usual with stronger-rooted things, especially if the roots of stronger-growing subjects have access to the border; in place of this I prefer keeping them in pots, as large examples of even the freest growing kinds can be kept in a healthy thriving condition in smaller pots than would be required by many hard-wooded plants.

When they are used as climbers, strong-growing sorts, such as *C. varium Chandleri* and *C. Lawrenceanum*, should be selected; these, when well managed, often make shoots 4 feet or 5 feet long in a season. Another matter of importance when to be trained round a pillar or similar position where they will be at a long distance from the roof is to grow the plants in a house where they will get plenty of light until they have attained sufficient size and strength, as if small, weak examples are thus used, they rarely grow away freely. Those who like to propagate their own plants will not find *Chorozemas* difficult to increase. Cuttings root readily in sand, treating them in the ordinary way in the matters of heat, moisture, and shade in a confined atmosphere. Shoots of moderate strength that are not too long, taken off with a heel when the wood is in a half-ripened state, should be chosen; these are generally obtainable in spring or summer from plants that have had some of their branches cut in more or less. Several may be put together in pots large enough to hold them. When well rooted, move them singly into small pots, stopping the points as soon as they begin to move. Keep in a growing temperature for a time, giving shade when the weather is bright. The atmosphere should be kept moderately moist until autumn, for, with these, as with young, newly-struck stock of most hard-wooded plants, it is well to treat in a way that will induce free growth until they have made some progress. With this view it will be better to winter them in a house or pit where they can have a temperature of something like 50°. In this they will keep moving gently, which is preferable to letting the plants get into a dormant state; and so treated they will be ready for shifting into larger pots as soon as the days lengthen. Some growers use loam for the stronger-growing kinds, but where peat of good quality is obtainable, I should give it the preference. The smaller-growing varieties, such as *C. Henchmanni* and *C. varium nanum*, should have peat. The shoots will again require stopping after the re-potting; how far this opera-

tion is to be carried with the strong growing sorts will depend on the use to which the plants are to be put. Where to be grown as climbers, no more stopping will be required than necessary to secure the requisite number of shoots to clothe the pillar or space they are intended to occupy. If these stronger growers are to be grown in bush form, the stopping will need to be repeated two or three times during the season. All that will be required afterwards is to give larger pots each spring, but, as already intimated, it is well not to overdo them in this respect, particularly as their roots are not of a character that will bear much or any of the old soil being taken away at the time of repotting. Each year after flowering, the freest-growing kinds should have their shoots shortened in moderation; if this is not attended to, they will naturally get straggling and bare at the bottom, conditions that must be avoided. The syringe should be used freely to all the sorts during the growing season, or red spider may be troublesome. T. B.

ACACIAS IN BLOOM.

EVEN in a small greenhouse some of the Acacias may be grown very successfully, while others require a large structure to attain a sufficient size for flowering. Of small-growing kinds, *A. Drummondii* with very deep green pinnate foliage, and bottle-brush-like spikes of pale lemon-coloured blooms, is one of the best when in a flourishing condition; but, unfortunately, such is not always the case, as it is by far the most difficult of all the Acacias to keep in a healthy state. The reason for this is by no means easy to discover, as however successful a person may be in one spot, he often fails if the same mode of culture be continued in a different place. A more vigorous plant in all respects is *A. lineata*, which can be flowered in as small a state as the last-named, though if allowed full development it reaches a height of several feet. In this the slender branches are thickly studded with little orange-coloured, ball-like flowers, and in this state they remain a considerable time. A great merit in this Acacia is that, whether 2 feet or 6 feet high, it is equally floriferous. The same may be said of *A. armata*, a species with bright yellow flowers and very dark green leaves, which are so thickly arranged along the branches that, generally speaking, a specimen of it presents a dense mass of foliage. It is one of the kinds that are grown for the London market, as it possesses the great merits of flowering in a small state, and of being in no way fastidious as to its requirements. A very curious species of Acacia is *A. platyptera*, whose winged branches at once mark it out for notice. Besides this character, equally prominent whether in or out of flower, it is also noticeable from the fact that it blooms throughout the winter, while the others do not commence to flower till the new year. *A. verticillata*, which was so well shown at the last meeting of the Royal Horticultural Society, is a handsome kind, but requires to attain a good size before it will flower well. For planting out in large conservatories it is one of the best; indeed, it is about the finest of all the large collection of Acacias in the temperate house at Kew, where every year a couple of large specimens of this kind are the admiration of everyone.

The large-growing *A. dealbata*, or Silver Wattle, forms a very handsome specimen regarded from a foliage point of view alone, and when laden with golden blossoms it is, of course, additionally attractive. This species requires to attain quite a tree-like size before flowering. One very different in habit from any of the above is *A. Ricciana*, with small needle-like foliage and sulphur-coloured blooms. It is a slender-growing shrub, and requires some support. For a rafter or roof plant it is well suited, as the long cord-like branches hang down for a considerable distance and dispose themselves in a very graceful manner,

so that the effect of a good healthy specimen when laden with flowers is most charming. The propagation of Acacias is by no means difficult, for seeds of many kinds can be easily obtained, and, as a general rule, they retain their germinating power for a long time. Regarded from some points of view, seedlings are preferable to cuttings, while in other respects the reverse holds good. When desired for planting in the sub-tropical garden, where it is often used in company with the still more vigorous *A. lophantha*, the Silver Wattle is best raised from seeds, and the plants grow more freely during their earlier stages than if struck from cuttings. If, on the other hand, it be the intention to flower the plant as soon as possible, cuttings are to be preferred. For this reason those that are required to bloom in a small state are best propagated from cuttings, and any required for foliage effect alone are more satisfactory when raised from seeds. H. P.

Ceanothus under glass.—Among blossoming shrubs, those of a white or yellow tint greatly predominate, and almost the only representatives with blue flowers are the different kinds of *Ceanothus*. If these are grown in pots and brought on during the season in a gentle heat they will be by now in flower, and the bright blue colour of their blossoms causes them to stand out conspicuous from all their associates. The best for this purpose I consider *C. azureus grandiflorus*, which is not only of a very pleasing shade of blue, but also flowers most profusely under glass. The first suggestion of employing the *Ceanothus* in this manner occurred to me by noting how early in the season it bloomed, even in a small state, when protected, for a few plants I had in pots intended for planting out against a wall were wintered in a frame with just a little heat, and in spring they burst out into flower. When needed for blooming in a small state, plants struck from cuttings should be chosen.—H. P.

Toxicophylæa spectabilis.—This is an evergreen stove shrub flowering at this season, and remarkable for the profusion of its blossoms as well as their delicious odour, which is perceptible for some distance. The individual blooms are small, but borne in closely packed clusters, not only on the points of the shoots, but also in the axils of the dark green leaves. When in full bloom the shoots are literally packed with flowers, so that the whole plant is then quite a mass of white. It is a native of South Africa, and can be increased by means of cuttings in the same way as many other stove shrubs, *Ixoras*, for instance. Though generally known under the above name, by the latest authorities the awkward sounding title of *Acokanthera* has been bestowed upon it. There is another species, *T. Thuubergi*, of more rambling habit than the last named, and inferior to it in beauty. This is seen at its best when allowed to ramble over part of the roof in a sunny position in the stove.—T.

Magnolia Campbelli and M. fuscata.—I think your correspondent "T. B.," whose letter about the above-named plants you print on page 280 of your last issue, cannot be personally acquainted with either of them, or he would never have recommended them for planting against a back wall of a high conservatory, for which, in my opinion, they are neither of them in any way suitable. As far as regards the first-named variety, which I consider the most magnificent of all flowering trees, as seen on its native hills at Darjeeling, in the Eastern Himalayas, he evidently knows little or nothing about it, as he says its flowers are white, instead of, as they really are, a lovely deep rose colour; and then he proceeds to state that it is a native of China, instead of Darjeeling. It has, I believe, never bloomed in Europe, save in the shrubbery of Mr. W. H. Crawford, at Lakelands, near Cork; and its lofty stature, reaching 80 feet on its native hills, makes it quite unfitted for restricted house or wall culture. Then, as to *M. fuscata*, its flowers are by no means fine, as stated by "T. B.," but small, dull, and insignificant in appearance, their only merit being the powerful and delicious perfume they exhale from time to time, as they are at other times absolutely scentless. The perfume, when ex-

haled, exactly resembles that of the sweetmeats known as pear-drops, from their shape. It is a low and slow-growing bush in no wise suited for a wall.—W. E. GUMBLETON.

FORCING PINKS.

WHY are not these useful subjects more grown, seeing they are of such a valuable and satisfying character? Everybody who cares for a fragrant flower loves the Pink, but by the aid of those varieties which may be termed early-flowering, they can be had in bloom much earlier than when grown in the open air. To flower them well they should be thoroughly established in their pots; and it is requisite that they be brought on gradually, and not forced in too great a heat—just enough to keep them moving without drawing the plants, as it is termed. It is also requisite to keep them as near the glass as possible, and when they are putting forth a full growth in early spring, give them a little weak manure water about twice a week.

The best forcing Pinks are Alice Lee, creamy white, extra fine for cutting; Ascot, soft, fleshy pink, with deep carmine centre; Derby Day, deep pink, laced with purple; Lord Lyon, deep rosy purple, extra fine; Mr. Pettifer, white and rosy purple; Mrs. Sinkins, pure white, probably the largest and best white grown; and Snowdon, white, but late. Now these are quite distinct from the doris-like laced Pinks, which are rarely, if ever, grown in pots, because they would thereby lose their lacing, which is their chief characteristic. The general rule with these is to plant them out in the open ground in raised and well prepared beds in the autumn, so that they can get well established by the time they bloom in May and June. Many of these fine laced Pinks are very beautiful, and it is a pity they are not much more grown; but they need high-class culture in the open to have the flowers finely laced.

Forcing Pinks should be propagated as soon as pipings or cuttings can be obtained, and they will strike freely in a gentle bottom-heat. As soon as rooted they should be planted out in a bed of rich soil, and then potted up early in the autumn, and placed in a house where they can be kept at a moderate temperature. R. D.

Cytisus filipes.—If for no other reason than the elegant growth of this species, it would be well worth a place in the greenhouse, but when as now the slender drooping branches are clothed with white flowers, very similar to those of the common Broom, it is additionally attractive. This *Cytisus* is a native of the Canary Islands, and is one of those good old plants that has been ousted out of most gardens to make way for novelties, though perhaps possibly inferior to these older introductions. There are several ways of increasing this Broom: it can either be raised from seeds, which are sometimes obtainable, or struck from cuttings. Besides this it can be grafted on the Laburnum, or allied kinds, and when this is done standard high, the long slender cord-like branches display their elegant drooping character to the best advantage. If grafted near the ground or struck from a cutting, and a leading shoot be carried up (at the same time shortening the side branches) till a sufficient height is attained, and then allowing all to grow at will, a pretty effect is produced, the whole plant forming a pyramid of drooping shoots.—H. P.

Azalea roseæflora.—It is now ten years since this pretty and distinct Azalea was exhibited in fine condition from the Tooting Nursery, and received a first-class certificate from the Royal Horticultural Society under the name of *Azalea Rollissoni*. Though introduced so many years, it is not even now cultivated to such an extent as one would have anticipated from its distinct and pleasing features. The cause of this to some extent is, no doubt, to be found in the fact that it is of very slow growth, taking years to form a fair-sized specimen, but as a set off to this it blooms profusely when but a few inches high. It naturally forms a dense, much-branched, globular-shaped bush, while the blooms are

of a bright salmon-pink colour, about 2 inches in diameter, and in a suitable temperature borne freely from November to the present time. They are very double, and when but partially expanded the origin of the specific name is more apparent than when the blooms are fully open. Our specimens have not been without flowers since last autumn, and there is a number of buds still to open. The plants were wintered in a structure that was seldom below 55° by day or 50° by night, and that this is about the most suitable for them was shown by the continuous display of blooms. After the flowering season is over the plants will be kept in rather a close atmosphere, and freely syringed in order to encourage as free a growth as possible, as upon that to a great extent depends the future display of bloom. Cuttings of the young shoots will strike root without difficulty, but as they grow so slowly afterwards the better way is to graft this variety on one of the stronger-growing sorts. When this is done the point of union should be as near the ground as possible, for if stuck on the top of a naked stem its globular habit of growth causes it to bear a good deal of resemblance to a mop. This *Azalea* is a native of Japan, and will pass through our winters in a cold frame, but the most satisfactory results are obtained where grown in a higher temperature.—H. P.

Rhododendron fragrantissimum.—This is a grand-flowered variety, bearing very large blooms of a pure white tint, except a blotch of lemon just at the base of the throat; the edges of the petals are also prettily crisped. The flowers are most agreeably scented, and though the perfume is by no means overpowering, it is very noticeable during sunshine, even in a good-sized structure. This *Rhododendron* is a hybrid between *R. formosum* and *R. Edgeworthii*, but the individual blooms are more showy than those of either of its parents. The habit of growth is rather straggling, and I once saw it treated as a greenhouse wall-shrub, and in this way, being planted out in a prepared bed, it grew away freely and flowered most profusely. The position in which it was placed was by no means heavily shaded, but just sufficiently so to break the full rays of the sun during the summer.—T.

Popular Palms.—Palms are grown in large quantities in the Clapton Nurseries, but the kinds for which there appears to be a special demand are *Kentia Fosteriana* and *Areca lutescens*. The former, from the Pacific Islands, has gracefully arching leaves and long, pendent segments, which render it very effective; its constitution, too, is so robust, that no amount of cool treatment appears to injure it. The *Areca* is a feathery-leaved kind, which, although a little more tender, being a native of the Mascarene Islands, is nevertheless a very useful plant. Its leaves, which are long and arching, are borne upon slender foot-stalks, which are orange-yellow, whilst the segments are bright, shining green. Of fan-leaved Palms, *Livistona borbonica* is grown here by thousands, and appears to be the chief favourite, the next, as regards popularity, being *Corypha australis*, which, although the hardier of the two, lacks the brilliancy of colour possessed by the *Livistona*. Numerous other Palms are grown by Messrs. Low, but none in such vast quantities as the kinds here enumerated.

Bouvardia Humboldtii corymbiflora.—This is perhaps the most valuable of all the *Bouvardias*, and its large heads of powerfully-scented white flowers are a great boon during the autumn and early winter; indeed, it is quite worthy in its season to fill the place of the *Stephanotis* and *Tuberose*. It is advisable to have two sets of plants in hand, viz., one-year-old and spring-struck cuttings, as the former (at any rate, when the planting-out system is followed) come earlier into bloom; in fact, they are quite a sheet of white some time before they require to be taken up. Where the stock has to be increased, a couple of old cut-back plants put into a Cucumber pit in January will soon furnish an abundance of cuttings. These should be taken off with a heel, inserted in a compost into which plenty of sand is worked, and plunged under a bell-glass in a good bottom-heat. The young plants should be shifted as soon as they are ready, and grown on quickly until the beginning of May, when they should be gradually hardened off, and then planted out early in June. A

warm, south border is the best place for them, and a good dressing of sand and either leaf soil or thoroughly well-rotted manure should be forked into the border before planting. Once planted, they will require no more attention, except a good mulching if the summer is very hot and dry. As in the case of all plants lifted in the autumn, it is advisable to run the spade round the *Bouvardias* once or twice prior to lifting, and this latter operation should be very carefully performed with old plants that are well in flower. They may either be placed for a time under a north wall or in a cool house with a little shade, as the state of the weather may require, until they have rooted into the new soil.—E. B.

SEASONABLE WORK IN PLANT HOUSES

TRAINING STOVE PLANTS.—In training the various kinds of stove climbers and twiners that are grown specimen fashion, it is necessary to pay some attention to the character of growth of the plants, without which their flowering is often interfered with. This especially applies to such kinds as *Allamandas*, *Stephanotis*, *Dipladenias*, and *Bougainvilleas*. The natural habit of growth in these and others of a like character is for their shoots to maintain more or less of an erect position. If, then, in a state of nature, the shoots of the twiners cling to the branches of other plants that happen to stand near them, and keep on extending in an upright direction until the time of their flowering arrives, when plants of this character are grown on trellises it is needful, when training them, to keep the points of the shoots well up. If they are bent downwards before the flower-buds are set the sap refuses to run in that direction, the result being that the back buds start into growth, ultimately starving the flowers, so that they generally fail to open. To avoid this mishap, it is better to provide wires or strings, attaching them to the roof, and on these encourage the shoots to cling until they set their bloom buds, after which they may be wound round the trellis. The shoots of *Allamandas* and *Bougainvillea glabra* ought to be kept as nearly erect as may be until the flowers are set and partially developed. To those who have not had much experience in the cultivation of the plants named and others of a like description, this may appear a matter of little importance, but success depends upon observation and attention to small matters.

CUTTING STRIKING.—The free-growing nature of most kinds of stove plants is such that cuttings in right condition for striking may be obtained at almost any time from spring until the latter part of summer, but in most cases it is best to propagate as early in spring as possible. Most stove subjects are proverbially quick growers that attain a useful flowering size in little time, and very often, unless where large examples are wanted, it is better to use moderate sized specimens than to retain the plants until they get old. Where the stock of any particular species or variety is insufficient, cuttings should be put in.

WINTER FLOWERING PLANTS.—Cuttings of the various kinds of winter-blooming plants should be potted as soon as they are sufficiently rooted. To allow the cuttings of quick-growing plants to remain in the pots in which they were struck until their roots get into a tangled mass, as sometimes done, interferes much with their future progress. Any young stocks of the character named that were struck early in the year, and have been growing in small pots, will soon require another shift. In the case of many it is better to now give them 5-inch or 6-inch pots rather than allow them to remain in the small ones in which they were first put until they are transferred to those in which they are intended to bloom.

EUCCHARIS.—Although the newer kinds of *Euecharis* that have made their appearance later than *E. amazonica* have handsome flowers, still they are not so reliable for giving a plentiful supply as the old species. In late years this most useful bulb has suffered severely from an insect that attacks the roots, but which is so small that

in many cases where it existed its presence was not detected. The safest course for those to follow who happen to have the plant in a healthy condition is to confine their cultivation to those they already possess, as from its exceptionally free-growing nature there is little difficulty in getting up a stock in little time. All the plants require is plenty of room and plenty of warmth, giving larger pots as they require them. By alternately growing and resting the plants they can be had in bloom at almost any time of the year, but though amenable to this kind of treatment it will not do to repeat it too often; better to be content with crops of flowers at longer intervals. Extremely free bloomer as *E. amazonica* is, there are some who find a difficulty in getting it to flower; the plants, though healthy and strong, keep on growing with little inclination to bloom, a circumstance that is no doubt attributable to something in the treatment—not unlikely want of rest. Where this difficulty exists it is best to turn the plants out of the pots, selecting a time when the last leaves that have been formed have attained their full size and are matured; the soil should be all shaken away, removing it carefully so as not to break the root fibres but as little as possible. The mass of bulbs ought then to be divided, putting the large ones in separate pots, singly or several together at the discretion of the cultivator, and keeping the smaller ones by themselves. Where this course is followed I never knew it fail to cause the plants to produce a full crop of flowers. In the matter of light the *Euecharis* is exceptional in its requirements to most plants, as it does not like so much as many things. This is apparent by the size the bulbs and leaves attain, and the quantity of flowers produced by plants that are grown in old, badly-constructed houses that do not afford light enough for the generality of things. In such structures, even when the plants are stood on the floor far away from the glass, they may often be seen doing as well as could be desired; whereas when these conditions are reversed the plants not unfrequently refuse to thrive, the leaves turning a sickly yellow colour, and coming gradually smaller until the whole plant, leaves, and bulbs are not half the size they should be. Plants that have recently flowered, or that have had a rest to prepare them for blooming, and that want more room should now be moved into larger pots; if the specimens are already as large as desired they may be reduced in size, dividing each into two or more pieces.

AMARYLLIS.—Bulbs that were started some time back will now be in flower, the leaves having made more or less progress. As soon as the blooming is over, if seed is not wanted, the flower-stems should be cut away and the plants placed where they will have a moderate amount of heat. It is essential that, whilst the young leaves are in course of formation, the plants should have plenty of light, without which the foliage is weak, a condition that prevents the bulbs increasing in size to the extent they should, and is alike opposed to the production of flowers another season. In the case of scarce and valuable varieties especially, nothing should be wanting that tends to increase the strength of the plants, as on this depends their ability to produce offsets, which, after taking into account the greater or less disposition in different kinds to increase in this way, will always be forthcoming in proportion to the strength of the old bulbs. In addition to the roots being kept sufficiently moist the leaves should be well syringed daily, as these plants are somewhat liable to the attacks of red spider.

ASPARAGUS PLUMOSUS.—This elegant climber and other sorts with a like habit of growth may now be increased by the division of the crowns. In severing the pieces, as many roots should be secured to each as possible; for this reason it is well not to carry the division too far. Give pots proportionate in size to that of the pieces, and keep them in a growing temperature until they have recovered from the check. Where seed has been produced they may be increased quickly, as

it vegetates as freely as that of the edible kind. The seeds may be sown at any time as soon as ripe, giving them a little warmth, and keeping the young plants in a genial temperature. Though these varieties of Asparagus have mostly been grown in heat, they will thrive in a moderately warm greenhouse, and where the plants are subjected to fire-heat the temperature should not be too high, otherwise the growth will be thin and weak, and the leaves wanting in the substance requisite to make them last when cut, for which purpose few plants are so well adapted or so enduring when the growth possesses the needful solidity.

AZALEAS.—Where a sufficient number of plants is at hand, there is no difficulty in having them in bloom from the latter end of the year up to mid-summer, but to admit of this there requires to be a corresponding difference in the time the plants make their growth and set their flower buds. There are few hard-wooded greenhouse plants that are so accommodating, or that will bear so much indifferent treatment and still keep living and blooming to some extent. To do justice to them, the plants now as they go out of flower should be moved to a house or pit where they will get plenty of light and can have the benefit of a genial growing temperature, in which they should remain until the buds are large and plump. As the sun gets powerful, a little shade in the middle of the day may be required. The atmosphere should be kept moderately moist, and the syringe ought to be used freely every afternoon. However strong the growth may be it is a mistake to stop the shoots as sometimes done; the plants look none the worse for being irregular in outline, and when the flowers are used in a cut state it is an advantage to be able to gather them with a good length of shoot attached. Where the plants make their growth at different times in the way here indicated, whatever potting is required should be carried out after an interval of three weeks or a month from the time the blooming is over, as then the roots will have begun to move freely, and they will at once take to the new soil; whereas if potted before the roots have started there is danger of the soil getting too wet before the young fibres enter it, a condition that must be avoided. In the case of any plants that show a disposition to make weak growth, but are otherwise healthy, they should be frequently supplied with manure water, or with concentrated manure of some sort. No pot plants with which I am acquainted are more benefited by assistance in this way than those if given when the roots are in an active state. T. B.

BOOKS.

REPORT ON THE EFFECTS OF THE FROST.*

I HAVE this morning received this publication, which I may say is, without question, one of the most valuable contributions to general horticulture which has appeared for many years. When I first suggested at a meeting of the scientific committee of the Royal Horticultural Society, in March, 1880, that such a report should be prepared, I did so on the ground that the summer of 1879 having been one of the wettest and coldest of which we had any record, and followed by a winter of extreme severity, it would be most useful to all gardeners, especially to nurserymen, to know what plants were capable of resisting the worst extremes of the British climate, and as this winter was followed by a second in which some of the conditions unfavourable to vegetation were repeated with even greater severity, we might fairly say that anything which was alive in the summer of 1881 was absolutely hardy. If this report could have

*The Journal of the Royal Horticultural Society, Vol. VIII. The frost report on the effects of the severe frost on vegetation during the winters 1879-80 and 1880-81. By the Rev. G. Henslow, M.A., F.R.S., F.G.S.

been published, as I proposed, six years ago, it would have been of even greater value than it is now, but though the matter has been repeatedly pressed on the council of the Royal Horticultural Society, it has been, for various reasons to which I need not now allude, withheld until many have almost forgotten the fearful devastation which was caused by that most disastrous summer and the two succeeding winters. But though I cannot look upon this report as by any means perfect either in the manner or the time of its publication, the cordial thanks of all gardeners are due to Mr. Henslow for the great pains and trouble he has taken in compiling and arranging this report, which, if I am not mistaken, will have a very large sale, and form an indispensable part of the library of every gardener. The report commences by an epitome of the character and effects of previous severe winters from 1837-38, in which many meteorological and horticultural facts are recorded. Then we have a sort of census of the number of species of plants killed and injured in the various groups of counties, into which, from a meteorological point of view, the country is divided, but I am not able to make out whether the number of plants mentioned as having been lost is the actual number of species, or whether repetitions of the same species in many different places are included. It seems, however, that in the following groups of counties there were lost, as follows:—

Group.	Number killed or injured.		Number of places from which reports were received.		Average at each place.	
	1879-1880.	1880-1881.	1879-1880.	1880-1881.	1879-1880.	1880-1881.

This table shows, first the large number of reports which were sent in from every part of the kingdom, viz., 272 in the first year, and 198 in the second, and to a certain extent the comparative severity of the weather both in the different parts of the kingdom and in the two seasons under review, and it will be observed that, though the number of reports is smaller, yet the comparative losses are heavier almost everywhere in the second than in the first winter. But, whether this is really the case, or only appears to be so from the way in which

the table is drawn up, I am not able to judge without a detailed examination of all the reports, though the remarks appended to many of them seem to show that many of the plants and trees and shrubs which just survived the first winter succumbed entirely to the second.

Then we have an index to the minimum temperatures registered. These are not, however, so important in their bearing on the ability of plants to resist cold as might be supposed. It is abundantly proved by the reports that it is not the degree of cold, but the favourable or unfavourable present and previous conditions of soil, climate, and position which determine the ability of plants to resist frost; and we know that many plants which die in England live on the Continent with a much greater degree of cold than they ever get here, whilst many other damp-loving plants live in England and die in Europe, not of cold, but of want of moisture. Then we have an index to the very numerous species and varieties of plants mentioned by the various reports, which has this great value, that it will enable the intending planter to judge of the hardiness of almost any plant (the list extends over forty pages) in many different parts of the country and under very varied conditions. A careful study of this ought to result in an immense saving both to nurserymen and to the public, as both are too apt to forget after a succession of mild winters that many plants which we grow or try to grow out of doors cannot be relied on to stand an exceptional winter.

Then we come to the reports themselves, which, though drawn up on a similar form, vary immensely both in their detail and in their completeness, and we must here remark that it is not in the home counties, for whose benefit the Royal Horticultural Society to some extent sacrifices the interests of its more distant and provincial fellows, that we find the greatest number or best reports, but among those amateur and professional gardeners all over England who ought to be and would be the backbone of the society when genuine horticultural work has to be done if they were properly represented in it. I notice with regret that the county of Middlesex only furnished two reports in 1879-80, of which that from Chiswick itself is one of the most meagre and incomplete, and though Mr. Barron states truly on Jan. 30, 1880, that the full effects of the frost are not yet apparent, yet he does not send in any report at all in the following year, when Dr. Masters, F.R.S., is the only contributor from the county. From Wimbledon and Kew, however, there are two full and excellent reports, furnished by the late Mr. Joad and Mr. Nicholson. Dr. Hogg, who was secretary of the committee appointed to collect evidence upon the whole subject, does not appear either in the first or second season to have sent in any report or otherwise to have taken any particular interest in the subject, and I believe that if the committee had been formed not out of a few of the members of the Scientific Committee, but out of the amateur and professional working gardeners of England, it would have produced a better, and certainly a more timely publication than the present one. But we have a number of reports of great value scattered through the volume, among which may be mentioned those of the late Mr. J. H. Mangles, of Haslemere, on Rhododendrons; Rev. Mr. Ewbank, in the Isle of Wight; Rev. H. Ellacombe, of Bitton; Mr. Shingles, of Tortworth; Mr. T. G. Parry, of Highnam; Mr. R. H. Holford, of Westonbirt, and others in Gloucestershire, which county appears to have

responded very well in this volume, perhaps because it has suffered so severely. From the Botanic Gardens of Edinburgh, Glasnevin, and Cambridge we have most valuable reports. From Mr. Dunn, Dalkeith, from Sir Charles Strickland, in Yorkshire, from Rev. H. Rawson, of Bromley, from Mr. Paul, of Cheshunt, from Sir J. Lawes, of the late Dr. Bull, of Hereford, Mr. Ingram, of Belvoir, and many others will be found reports containing invaluable information which will well repay a careful perusal.

Mr. Henslow concludes his preface by saying that he shall be glad to receive any remarks or corrections which the authors of the reports may desire to make. He does not, however, say whether these are to be published, and if so, how or when. It would also, I think, be well to state whether this volume is for sale to non-members of the society, as, if not, I advise those who wish to have it to get one by becoming a member under the new rules before it gets out of print, as by so doing they may save themselves both in time, money, and disappointment more than several years' subscription to the society will cost.

Presbon, Cirencester.

ORCHIDS.

W. H. GOWER.

FLOWERING ORCHIDS AT STREATHAM.

IN Mr. Measures' garden, at The Woodlands, these plants are just now superb. Perhaps one of the greatest surprises for an Orchid-grower are the immense specimen *Cymbidiums*. These, either in or out of flower, are both graceful and orna-

mental. So large have these specimens become, that they have quite filled up the house they are growing in, and a new one, built expressly for their accommodation, is now fast approaching completion. The kinds we allude to are *C. Lowianum*, *Hookerianum*, and *giganteum*. These plants are some 12 feet in diameter, with long, graceful, deep green leaves. Specimens of *C. Lowianum* are now bearing eight and nine spikes upwards of 5 feet long, each spike carrying twenty-eight and twenty-nine flowers, the individual blooms being about 4 inches across. The sepals and petals are apple-green (becoming lighter with age and then yellowish), streaked with a few lines of chocolate-brown; the three-lobed lip is creamy white; middle lobe, brownish purple in front margined with yellow. This plant was introduced from Burmah by Messrs. Low, of Clapton, some ten years ago. It belongs to the same section as *giganteum*, which blooms during the winter months. Although these plants are natives of Burmah, which is generally credited with being very hot, they thrive best in an intermediate or *Cattleya* house. They produce large fleshy roots in abundance; therefore ample pot-room should be allowed. The soil most suitable for these *Cymbidiums* is two parts loam and one of peat, adding some sharp sand to keep the material open and sweet. They should not be potted above the rim of the pot in the manner usually adopted for Orchids, but the ordinary system of potting terrestrial plants should be followed, leaving ample space to receive water, of which they enjoy a bountiful supply when growing. The smaller-growing *C. eburneum* is also growing here largely, and is now flowering in abundance. The finest plant has now expanded thirty-five of its large ivory-white flowers upon eighteen spikes; whilst dozens of small plants are equally floriferous in proportion to their size. This species was introduced about forty years ago, when, as it came from the East Indies, it was treated to the hottest corner of the East Indian house. Under these conditions it seldom flowered, and although its beauty was admitted by all, it lost favour on account of its shy blooming qualities. About fifteen years ago, Mr. Williams, of Holloway, obtained some plants from Northern India, with the information that naturally they grew in a cool district. When this treatment was adopted the plants soon began to show increased vigour and to become free flowering, and hence have increased

the roof of a small light house bearing numerous branched spikes, some of which are carrying thirty and thirty-five flowers upon each spike, whilst quantities are still kept cool and dry to flower later on. *O. Rossi majus* has now become a common Orchid, but, nevertheless, none the less beautiful. Among the many forms which have come under our notice none equals the highly coloured variety now in this collection; the sepals are cinnamon-brown, faintly mottled; petals very broad, rich brown, saving a deep marginal border of rosy peach; lip rosy peach, yellow at the base. *O. Herberti* is a hybrid of the crispum type with creamy white sepals and petals, freely mottled and barred with chestnut-brown. Other species now flowering are *O. Sanderianum*, an excellent form; *O. nebulosum* in variety, and *O. Oerstedii*.

AMONGST *CATLEYAS* now opening, the new and beautiful *C. Lawrenceana* stands in the first rank. The plant is quite distinct in its habit of growth, and bears numerous flowers upon a spike in the way of *Skinneri*. In the variety *Lawrenceana* they are double the size of *C. Skinneri*, and quite different in colour. In the plant now blooming with Mr. Measures the sepals are deep rosy purple, and the lip intense magenta crimson. It is a free-growing plant, and thrives under the same conditions as *C. Skinneri*. *C. nobilior* is a handsome dwarf species in the way of *Walkeriana*, and produces its flowers in the same manner upon a leafless stem; sepals and petals soft rosy mauve, the latter very broad, with a central streak of deep rose; lip soft rose; side lobes very large, the centre of the lip ornamented with a central patch of creamy yellow; the blooms are very fragrant. This plant succeeds best grown upon a block of wood, and likes exposure to the light. Examples of the Mexican *C. citrina* are also now flowering; its deep yellow, fragrant blooms, and its habit of growing downwards renders it totally unlike any other species. A few of the best forms of *C. Trianae* are still in flower, but they will soon be succeeded by *C. Mendeli*, one very fine form of which is already expanded, its flowers measuring upwards of 8½ inches across; the sepals and petals are very broad, white, with just a very slight tinge of flesh colour running through them; lip very long, front lobe magenta-purple, beautifully frilled on the edges, and the base stained with pale yellow. The flowers of *Cattleyas* should be carefully preserved from sprinklings from the syringe, or they speedily become spotted and decay.

VANDAS are also a great feature in this collection, numerous forms of tricolor being now in flower, also the distinct and beautiful *suavis*, their flowers yielding a powerful and grateful perfume; here also we noted the superb form of *V. cristata* with its curious flowers, the lip being ornamented with lines of blackish purple. *Angraecum sesquipedale* is also flowering freely, even upon quite small plants, its large ivory-white flowers affording an excellent contrast to its two-ranked, bluish green leaves. This species we have observed, when grown in heavy shade, produces flowers of a creamy white, which are inferior in beauty. Associated with these are examples of *A. citrina*, with numerous racemes of its pearly flowers. *Phalenopsis Schilleriana* and *amabilis* are thriving admirably mixed with other Orchids; numerous *Dendrobies* are also yielding a brilliant display, the most striking being *Ainsworthi*, various fine forms of *nobile*, *crepidatum*, *splendissimum*, *heterocarpum*, *Wardianum*, *suavissimum*, with dozens of spikes of its rich yellow and deep velvety black flowers, *crassinode*, *crassinode album*, and its variety *Barberianum*, which is a more robust grower than the typical form, and produces flowers of greater size and more highly coloured; these knotted stemmed kinds appear to require a thorough season of rest to induce them to produce their flowers in abundance. *Dendrochilum glumaceum* is largely grown on account of the delicious odour of its flowers; we observed numerous specimens bearing forty and fifty of their pendent racemes, and one magnificent specimen carried some seventy or more of its fragrant clusters. *Dendro-*

Cymbidium eburneum.

mental. So large have these specimens become, that they have quite filled up the house they are growing in, and a new one, built expressly for their accommodation, is now fast approaching completion. The kinds we allude to are *C. Lowianum*, *Hookerianum*, and *giganteum*. These plants are some 12 feet in diameter, with long, graceful, deep green leaves. Specimens of *C. Lowianum* are now bearing eight and nine spikes upwards of 5 feet long, each spike carrying twenty-eight and twenty-nine flowers, the individual blooms being about 4 inches across. The sepals and petals are apple-green (becoming lighter with

age and then yellowish), streaked with a few lines of chocolate-brown; the three-lobed lip is creamy white, independent of their agreeable perfume. This species should also be grown as a terrestrial plant, and the same potting material suits it admirably. *ODONTOGLOSSUM CITROSUM* is another plant which is grown remarkably well here. The plants are kept cool and very dry during winter, even to the shrivelling of the pseudo-bulbs, until just before the spikes appear, when they are removed into a higher temperature and bright light, and liberally supplied with water. At the present time there are dozens of plants suspended from

chilums are somewhat delicate plants, and should not be subjected to too severe a resting season. *Cologynas* and *Lycastes* are still yielding a bright show; amongst the former are grand examples of the pure white *cristata alba*, with six and seven flowers upon a spike, likewise *Lemoniana* and *maxima*. These *Cologynas* should be grown in a cool house during the summer months, applying more heat in the beginning of autumn, which causes their pseudo-bulbs to swell up well. The pure white form of *Lycaste Skinneri* has borne the astonishing number of sixteen flowers upon one bulb, including a twin-flowered spike. A superb form of *L. Measuresiana* is now exceedingly attractive, its flowers are erect, sepals spreading olive-green or bronzy brown in some forms, petals large, reflexed at the tips, ground colour creamy white; this, however, is scarcely visible, except on the edges, as the whole surface is covered with close lines of bright velvety crimson, lip same colour, the centre lobe plain creamy yellow in front. This variety is, we believe, an enlarged and highly coloured form of *L. plana*. Under the cool system of growing these plants, *Lycastes* have proved to be free-flowering to an extent never calculated upon by growers in the early times.

THE LADY'S SLIPPER ORCHIDS (*Cypripediums*) are, however, perhaps the most striking feature of the Woodlands collection, as it contains close upon 200 distinct forms in the shape of hybrids, varieties, and species, some few kinds existing only here. Amongst the most notable in bloom just now are *C. villosum aureum*, with seven of its canary-yellow blooms; the typical *villosum*, with upwards of forty flowers; *Boxalli* in numerous varieties; *Haynaldianum*, *hirsutissimum*, *calophyllum*, *Peteri*, and *tonkinensis*, which has most elegantly marbled foliage, the flowers being about the size and shape of *Godfreyae*, the colours and markings of it, *niveum*, and *concolor* appearing to be all combined in one; other kinds are the beautiful *callosum*, *Lawrenceanum*, *Lceanum*, *superbum*, *Fraseri*, *porphyreum*, *nitens*, this last a most showy and ornamental kind, having been obtained by crossing *villosum* and *insigne Maulei*. Many other varieties too numerous to note, except when in bloom, are also grown. This collection of plants is grown cool, and none of the houses are so unpleasantly hot or so wet but that the most delicate might walk through them to admire the beauties of the flowers. Moreover, Orchids grown in this way do not suffer by removal to the dwelling-house, and Mr. Measures uses them to a large extent for indoor decoration.

Pleurothallis scapha.—This belongs to a family of Orchids which some few years ago was well represented in our gardens, the flowers of which, although extremely beautiful when magnified, failed to please the growers of this Order; and immediately the larger and brighter coloured flowers of their relatives, the *Masdevallias*, became known, *Pleurothallis* began to disappear. This species, however, bids fair to reinstate the name in Orchid collections. The spike bears from six to eight flowers, each flower measuring some 4 inches in length, very singular and fantastic in shape. The sepals project forward, whilst the petals stand almost erect, the colour of these being creamy white, tinged with purplish crimson. We noticed this singular plant recently in the nursery of Mr. William Bull at Chelsea. *Pleurothallis*, like *Masdevallias*, thrive in the coolest temperature.—G.

A photograph.—Adverting to what you said in last week's GARDEN on photography, I beg to enclose or your inspection a photo of a fairly good spike of *Odontoglossum Alexandrae* drooped across a basket of *Adiantums* and *Davallia* (I think) dissecta. The variety of the *Odontoglossum* is a good one, almost pure white, and the spike bore fifteen flowers a little larger than they appear in the photo. One unopened bud is not included. The plant was grown in a cold fernery all the summer, and bloomed in the autumn in a cool stove.—GREENWOOD PIM.

* A large and beautiful photograph, too large for our engraving without reduction. Photography will be effective in preserving for us and emphasising,

so to say, one of the greatest charms of these plants—their often fine form.—ED.

Cymbidium Devonianum.—I see in THE GARDEN that you describe and name Orchid flowers when sent to you; I therefore send you by post the stem of a *Cymbidium* with thirty-two flowers. The plant was sent to me with some plants of *C. eburneum* and *Mastersi* by my cousin, Sir Hugh Gough, from Assam, and the remark of the collector was that it was a splendid variety and scarce. The leaves are from 12 inches to 18 inches long, broad at top and tapering to the base; the plant is free-flowering. There are two more stems with the same number of flowers hanging over the side of the pot. Will you kindly name the plant?—G. GOUGH, *Clonmel*.

** The fine raceme sent is that of *Cymbidium Devonianum*. It is a very distinct and handsome species, and rare in cultivation.—ED.

Resting Orchids.—I have a *Laelia purpurata* just finishing its growth with a fine flower-sheath; also a *Cattleya Moesta*, which made one strong growth whilst it was flowering last summer, and before this was completed started a second growth from it; this is now nearly completed, though still making roots. Both are enormous bulbs, being nearly eighteen inches long with leaves. They have both large flower-sheaths. What I am desirous of knowing is, whether these plants should be rested now until the flowers begin to push in the sheaths, or whether it is now too late in the year, and if it would be better to allow them to make further growth. If so, would this prevent the flowers coming? Kindly say also if summer and autumn-flowering *Dendrobiums* ought to be rested until the flowers begin to show.—E. R. WHITWELL, *Barton Hall, Darlington*.

Odontoglossums at Mr. Low's nursery.—It is rather early to see these at their best at Clapton, but from the many thousands of spikes just pushing up a grand display may be reasonably looked for later on; some few distinct and handsome kinds in flower, however, are deserving notice, amongst which *O. baphicanthum* is conspicuous. Some rank this as a variety of *O. odoratum*; the sepals and petals are soft yellow with several chocolate-brown spots, middle lobe of lip lengthened out into a slender recurved point, white or canary-yellow blotched with reddish brown, crests yellow streaked with red. Another handsome form is *O. Willecanum*, originally introduced by Mr. Low, and supposed to be a natural hybrid between *O. crispum* and *O. luteo-purpureum*; the flowers are between 3 inches and 4 inches across, sepals and petals soft yellow blotched and barred with reddish brown, and waved at the edges; the lip resembles *O. crispum* in shape, but the colour is pale yellow blotched in the middle with a large spot of reddish brown, with serrate edges. *O. Halli*, which is perhaps one of the finest of the *Odontoglossums* yet introduced, is also in flower; the panicle is much branched, bearing dozens of flowers upwards of 3 inches across; the sepals and petals are buff, variously blotched with deep brownish purple, lip large, tapering to a sharp point, beautifully toothed at the edges, crest much toothed, streaked with bright yellow, and blotched and spotted with purplish brown. Many fine forms of *O. Roezli* are now in great beauty. *O. Pescatorei* and *O. crispum* are not yet sufficiently advanced to detect extra varieties, and *O. luteo-purpureum* and *O. pulchellum majus* close the list at this time.—G.

SHORT NOTES.—ORCHIDS.

Trichopilia lepida.—What is the difference between *Trichopilia lepida* and *Trichopilia crispata*? The former is unknown to me, and I wish to know if it is a variety of the latter.—ORCHID CORRESPONDENT.

Odontoglossum aspersum violaceum.—A lovely variety of this plant, which Professor Reichenbach supposes to be a natural hybrid between *O. maculatum* and *O. Rossi*; at first sight the flowers of this form may be taken for *O. Rossi*, but a closer inspection shows them to be abundantly distinct. We recently observed this rare and beautiful variety flowering with Messrs. Shuttleworth & Carter, in their nursery at Clapton.—G.

Oncidium cucullatum.—This is one of the easiest grown plants, provided it receives cool treatment, and is admirably adapted for cultivation in a Wardian case. It is essentially a winter bloomer, and its large distinct flowers last long in perfection. Although small in distinct the flowers

are large, the sepals and petals small and dull purple, lip large, deep mauve profusely spotted with violet. This *Oncidium* is found on both sides of the Andes of South America, but whilst the plants on the Atlantic side are found at considerable elevations with large flowers, the form on the Pacific side is found at much lower elevations, and the flowers are smaller and altogether inferior.—G.

KITCHEN GARDEN.

HERBS FROM SEEDS.

SEVERAL of the herbs in common use are herbaceous in character, and are readily increased in the spring by dividing the roots. If there is no stock to divide, the present is a good time to raise them from seed. Winter Marjoram is much in demand. It can be raised from seed if sown now and placed in a gentle warmth. When sown out of doors it is a long time in germinating and sometimes does not vegetate at all. A 6 inch pot will hold as many plants as a large garden requires, and the plants may remain in the pot until large enough to be planted out. Sage.—A hard winter often destroys the whole of the stock of this common plant, especially in a retentive soil. When such is the case a fresh lot of plants may soon be raised from seed, which may be sown either in pans and the plants brought on under glass or in the open. Thyme.—The common Thyme is readily increased from seed, but as the seeds are rather small it is desirable to sow in a pan and raise the plants in the greenhouse or cold frame. If the plants are not growing too thick in the pan they may remain undisturbed until they can be planted out. Tarragon.—The seeds of this herb do not vegetate freely, and it is best to place the pan in which the seed is sown on a hotbed or in a warm house, and as seedlings make long tap roots they must have a deeper soil than the others. As soon as they are large enough plant them out in some rich soil in the open. The first year they may be in lines 9 inches apart, and in the following spring be planted where they are to remain.

Amongst annual herbs, Basil is much used in some families. Sweet Basil is the one commonly grown. There is another form which is called Bash Basil. Both are tender plants, so it is best to sow the seed in April and grow the plants under glass. If sown out of doors a warm border must be provided. When required for winter use the plants should be pulled up when well in flower, and tied in small bundles and dried in a cool shed. Borage.—This is a coarse growing subject, which if not wanted early in the summer may be sown in any odd corner of the garden; but if required in the month of June, a few seeds had better be sown in a 9-inch pot, and the plants grown on in a cold pit. Chervil.—This is a hardy annual, and may be sown out of doors, but as the spring sown plants quickly run to seed, a second sowing should be made at the end of May and another in August to stand the winter. Dill.—Although this herb is not much called for, it is so easily grown that no one need be without it. A little seed scattered thinly on the surface and raked in will furnish a supply from July until late in the autumn. Fennel.—Seedling plants of this are better than root cuttings, as they do not so quickly run to seed. Any number may be raised by sowing the seed now in pans, or in the open. If time is an object, a few seeds may be sown in an 8-inch pot, and they will quickly afford a supply. Parsley.—Although this is an herb which is so universally grown, there is hardly another subject cultivated in the garden that causes more trouble and anxiety. This arises from various causes. In many gardens the soil is too rich, and then it continues growing so late in the autumn that the first severe frost terribly cripples it, if it does not kill it outright. In some cases an insect attacks the roots, causing the whole of the plants to die off. In our case a retentive soil and a damp climate cause a great loss of plants during the winter, and had we not ample room in a cool Peach house in which to plant it out during the summer, reserving them for winter and spring use, we should not have any left. Whether the ground is rich or poor, I am satisfied

that damp is as great an enemy to it as frost. If I had no convenience to provide a supply under glass, I should sow the seed on a dry bank in June. The bank of earth should be 1 foot high at the back and facing the south. If the bank is formed about the end of July, strong young plants may be dibbled in about 9 inches apart, when they will get well established before winter, and afford a supply when plants on the flat have been all killed by damp or frost. J. C. C.

LETTER FROM BURGHEY.

TO THE EDITOR OF THE GARDEN.

SIR, —You ask why I do not raise a hardy Broccoli. I answer, because we have plenty. A hardy Broccoli is not wanted. What we want is men who know how to grow Broccoli. Now I will give you in writing a photo of your Broccoli at Gravetye Manor: Great big plants from 2½ feet to 3 feet high, with a green bunch at the top of each. Well, you will see, the frost always kills the stems of Broccoli between the soil and the head simply because it has no protection; this is called in garden language, catching them between wind and water. The reason is, that your Broccoli was sown too soon; 10th of May is your time for spring Broccoli. What I mean by your time is, your locality being south, that date is soon enough. Doubtless yours was sown in April, and allowed to grow into leggy plants before being planted in their final places. You should have in your case laid them down with their heads to the north. I never do, because I always have short stems, the leaves touching the ground. Here is the system of growing Broccoli: Sow first week in May. Immediately the plants have four or five leaves, plant them out finally from the seed bed into good firm soil; an old Strawberry bed is a capital site. Cut up old plants at the ground line, rake off rubbish, set your line, make holes with a crow-bar, put in the plants, and make the hole full of mud by pouring water all round it. You then have still plants close to the soil, stem protected by Nature's own protection, and plenty of Broccoli. Whereas, plant them in manured and trenched land you have a mass of good plants, but no firmness or sinew in them. The first frost, down goes the Broccoli never to rise any more.—R. GILBERT

* * * This is excellent advice, but we have noticed this year that some Broccoli not strongly grown, including some of our own, were almost killed by the winter: whereas, the Purple Sprouting under the very same conditions was in perfect health and quite pleasant to look at compared with a ragged remnant of the best Broccoli. Therefore, some kinds of Broccoli being uninjured by the weather, we thought a vegetable improver of our friend's ingenuity would be able to give us a really hardy Jubilee Broccoli. What he says about cultivation is worth everybody's consideration.—Ed.

SHORT NOTES.—KITCHEN.

Wanted, a hardy Broccoli—I quite agree with Mr. Record in his article on p. 289, March 26. My own are dreadful to go near.—ONE WHO SMELLS THEM.

Dells Crimson Beet—We have tried many kinds of Beet during the last ten years, but none of them have proved so satisfactory as this variety, and as a main crop variety I consider it the best in cultivation. It has a compact top, not too large a root, and the quality is first-rate.—J. MERR, *Michigan*.

Spinach—A bed of the ordinary round or summer Spinach, sown the first week in September last, has stood the winter better than three other beds of the prickly sown at different times. We have not gathered any quantity from this bed, but as soon as we have warm, growing weather I have no doubt it will be a long way ahead of the others. The plants on these beds have been gradually dying away since autumn, and the late cold weather finished more than half of the remainder; while the summer variety has not suffered in the least from frost. A bed of this will be sown for the future to stand the winter.—W. HOWARD, *Robt.*

Onions and frost—It is strange that whilst really ripe, matured, hard Onions will soften and rot under the influence of winter frost if so exposed, yet old growing bulbs or plants stand through the hardest of weather in the open ground comparatively unharmed. Both last and the preceding summers being

dry, I found a quantity of plants in a bed refusing to bulb or ripen, though the earlier ones did so well. Left standing all the winter in each case the plants, though very strong and the bulbs full of sap, stood the weather admirably.—A. D.

KITCHEN GARDEN NOTES.

ASPARAGUS—Spring has burst upon us suddenly, as did the late storm, and vegetation is making rapid progress. The first heads of Asparagus in the open plots we observed when giving the plantations a dressing of salt and soot on the 22nd ult. This application we give as much for the prevention and destruction of weeds and slugs as we do for its fertilising properties, as before we adopted this practice slugs, in a wet season, worked sad destruction by taking out the points of the shoots almost before they had emerged from the soil. The plot—two years planted—though not intended to be cut this season, we have served exactly the same, as we like to keep every stem that shows from getting crippled or weakened in any way, and with that intent we sometimes have recourse to tying to small sticks those stems that seem likely to come to grief by a wind storm. We have a new plantation to make, and this we hope to accomplish in a day or two.

SALSIFY AND SKORZONERA—The demand for these is very trifling. We prefer to sow both early in March, but being hindered at that time they have this week been sown on deep sandy soil, and in drills 14 inches apart, and the seedlings will be thinned out to about 9 inches apart in the row. Salsify is the most in favour, and a proportionate larger space is therefore devoted to it. I fancy that both would be more popular but for the trouble involved in preparing small roots for the table. If we were to bestow greater pains on their cultivation, so as to get the roots clean and half as thick as one's wrist, they would be used more frequently, and thus the season of other vegetables would be prolonged.

CAULIFLOWER AND CABBAGE—It is now safe to plant out all Cauliflowers that have been wintered in frames. They should have the richest soil, be planted in drills, and each plant be lifted with soil adhering to its roots, and if there should be any cause to fear "clubbing," surround each plant with sifted mortar scraps, and if mixed with soot, it will be all the more effective; well water in the plants and they will show no signs of having been moved. Cabbages do not require the same care in transplanting, but even these repay the extra labour involved in digging up the plants carefully with a fork, to make certain of securing all the roots, which, if large or spreading, should be planted with a trowel, as in the case of Cauliflowers. A dibber will do for planting them, provided the roots are small and the soil loose and friable, but in heavy soils the use of trowels is always to be preferred. Our first sowings of Cauliflowers and Coloworts that was made in warmth and pricked out in frames are nearly ready for planting in the open ground, the final preparation being the gradual inuring them to bear without check full exposure to the open air, by leaving some continually on the frames, except in frosty weather. Others will be pricked out from seed pans in the frames shortly to be vacated by planting out the autumn-sown Cauliflowers; and in these frames also will be pricked out our first sowing of Celery.

SEAKALE—As we are nearing the end of forcing, we have had the ground prepared for making a fresh plantation, principally of the medium-sized pieces of the forced roots, which have been preserved by laying them in sand as soon as the Kale was cut. These pieces are cut into lengths of from 4 inches to 6 inches, and the side rootlets rubbed off; when they are ready for planting, and the ground being deep and loose, the handiest way is to dibble them in, the top of the set being about an inch under the surface. Sometimes we plant in rows as close together as 18 inches and a foot apart in the row, but this is only when we

expect that rich ground and good sets warrant the hope that the roots will be ready for next season's forcing. When conditions do not favour such a prospect it is better to plant in rows a yard, or even more, apart, and the first year take a catch crop of Lettuce or French Beans from the intermediate space. The Kale will require the whole space in the second season. If it is intended to raise plants from seed, now is the time to sow on highly manured ground in drills 20 inches apart, thinning them out to 9 inches from plant to plant as soon as the seedlings are 2 inches high. Seakale will appropriate and return with good interest any amount of high feeding in the way of manurial mulchings and manure water that can be spared, and, lacking this, frequent deep hoeings should take place throughout the summer and flowers be kept regularly picked off.

BROCCOLI—The slaughter amongst these in this not always favoured southern district has not been greater since 1879 and 1880. The only varieties that have escaped are about half the plants of Snow's, Lauder's Goshen, Late White, about 80 per cent of Model, Safeguard, Late Queen, and every plant of Purple Sprouting. The season is an exceptional one, and may not be repeated for years, so that we do not intend to give up growing other varieties, otherwise we should have but a short season, as, except Snow's, none of the kinds named are ready for use till the middle of April; but we shall take special care to have the varieties named in quantity. There is little doubt but that in some degree we are sometimes ourselves to blame for the winter collapse of Broccoli by sowing so early, that the plants get so large and overcrowded that hardening or ripening is hindered, as sun and air cannot reach them. If, when it is thought this error has been made, the plants in early autumn are gently lifted with a fork, the check thus produced will probably have the desired effect, that is, of hastening the hardening of the plants. Laying down the plants with their heads to north or west, with a view to safe wintering, we long ago discontinued as being of no avail, as on comparison quite as many plants survived that were not thus treated, and in other respects were superior, the heads finer than the laid-down plants, so that from choice we should never again revert to the practice.

FORCING—The first batch of Tomatoes intended for fruiting in pots has now been given their final shift into 9-inch and 10-inch pots, a short stake is placed to each, and for the present they are placed in the second vinery, which is kept at a minimum night temperature of 60° and 65° by day. The plants to be grown outside are now in 3½-inch pots, and are being kept stocky by giving them just sufficient warmth to keep them quietly on the move. Cucumbers sown at the new year, and planted in a house with hot-water pipes for bottom-heat, are beginning to fruit, and the main shoots require stopping once a week; the side laterals we keep regularly pinched at the joint in front of the cluster of fruits that we intend to leave; such clusters are in most instances reduced to a single fruit—sometimes two are left—as soon as the best-formed fruits can be discerned. The border space is only 2 feet in width and of about the same depth, including the drainage, so that it is necessary to give rich top dressings frequently so long as the plants continue in full fruit, which, if kept free of spider and fly, they will do till we can get supplies of fruit from frames at so late a period as to enable us dispense with, at least, part of the labour that frequent renewals of linings entail. The temperature of the house ranges from 60° to 80°, according to the state of the weather, and both plants, floors, and walls are well syringed in bright and drying weather, but we are very sparing with moisture when the weather is cold and wet; otherwise, that worst of all pests, mildew, would quickly put in an appearance. French Beans do well in this kind of structure, the heat and moisture required for Cucumbers being every way suited to them. The last sowing for this season's forcing has been made on a bed of soil in a heated pit. Potatoes, Carrots, and

Radishes in manure frames now demand increased attention as to airing, and, if time can be spared, the linings will once again be renewed. Celery will very shortly be ready for pricking out, and the plan most in favour with us is to set a frame on a hard surface, into which is put from 4 inches to 5 inches of light soil—leaf-soil principally; this is beat down firmly and well watered, which further consolidates it, and it is then ready for the plants, each of which is afforded 3 inches of space. The merit of this plan of treatment is that the plants lift with such balls of soil that they transplant without the slightest injury.

TREES AND SHRUBS.

W. GOLDRING.

THE LARCH AS A LAWN TREE.

MR. MARNOCK was not singular in his opinion when he said some time since that "the Larch as an ornamental tree is much neglected." It is indeed a neglected tree in ornamental planting, even in parts of the country where it is not grown in plantations for timber. Perhaps it is because it is such a common plantation tree that it is ignored by planters, yet in the whole range of ornamental trees there is certainly none more beautiful than a vigorous young Larch, particularly when seen in early spring just as its tassels of new foliage unfold accompanied, may be, by strings of tiny cones brightly

Coning branch of Larch and winter twig.

coloured and fragrant. The Larch, like the deciduous Cypress (*Taxodium distichum*) seems to burst out suddenly with the freshness of its young leafage, but the exquisitely graceful growth of the Larch makes it the most beautiful tree of the only two deciduous Conifers commonly cultivated. To be really beautiful as a lawn tree, a Larch must be young, vigorous, and well cared for from its youth upwards, and must always have plenty of room about it to develop itself fully; otherwise, it soon loses its branches, and then half its beauty is gone. An old plantation Larch is not a lovely object, not even picturesque, as an old Scotch Fir generally is; but, planted in good soil in a sheltered spot on a lawn, and perfectly isolated, a Larch may be kept in perennial youth, so to speak, and produce a finer effect than half the modern Conifers which crowd every garden. I remember seeing last year a grove of young Larches on a lawn that greatly impressed me by their elegant growth. They were of different sizes, the tallest being about 30 feet, the shortest about 10 feet, and they were so grouped that the whole mass, numbering about a score, looked as if they were Nature-sown seedlings, so informal,

yet so effective, was the outline of their tops. The spot was sheltered by a plantation from the prevailing winds from the south-west, and the soil was good, so that the trees were in favourable circumstances. A grove of Larches, including besides the common, the American, Japanese, and others, should be planted in every good garden, on a lawn, or in the pleasure grounds.

Portugal Laurels by the seaside.—For general planting near the sea the best shrubs are to be found among Evergreens, though some of these do not appear to thrive any better than the deciduous trees, and among the worst is the Portugal Laurel. Within the shelter of the low walls in front of the villa gardens facing the beach it grows, but above the shelter of the wall it makes

florim, and other winter and early spring-flowering plants. It is perfectly hardy; its blossoms are succeeded by its very handsome variegated leaves, so that the plant is an exceedingly interesting object at all seasons of the year, and it deserves to be more extensively planted than appears to be the case. It is well suited for a lawn plant or for the shrubby border. It naturally forms a spherical bush some 6 feet or 8 feet in height, and can readily be made to assume a pyramidal or standard form, and will succeed in any description of soil. It is a native of Austria, but has long been introduced to this country.—P. G.

The Minorca Box.—I look upon this as the handsomest of all the Boxes, and its large leathery foliage makes it distinct from all the varieties of the common kind. *Buxus balearica*, as it is botanically called, is indigenous to the Balearic

A young European Larch.

no progress, and the tops look as if they had been scorched by fire. Beside the Portugal Laurel, and fully exposed to the blast—and we should say within reach of the spray from the sea—the *Laurustinus* thrives amazingly, making a large and densely-furnished bush, such as is seldom seen in inland situations. It is quite a substitute for the Laurel.

Cornus mascula variegata.—The male Cornel or Dogwood among hardy flowering shrubs may be regarded as one of the earliest harbingers of spring, its numerous small umbels of unexpanded yellow flowers being sufficiently forward to render the plant very ornamental even as early as the middle of February. The flowers, however, remain long in the bud state, and being produced in great abundance render the plant a suitable companion for the *Chimonanthus*, *Jasminum nudi-*

and other islands in the Mediterranean, as well as to Italy and Turkey, where it forms a magnificent tree of from 60 feet to 80 feet in height. It was first introduced into Britain in 1780. The leaves are similar in form, but nearly four times as large as those of the common Box, and when grown exposed to the sun, of a much lighter green. They are thick and leathery in texture, and very abundantly set on the branches. The flowers are small and inconspicuous, of a light yellow colour, and generally expand in July. In our gardens it is only seen as a moderate-sized shrub: and, though very properly classed among hardy Evergreens, it only succeeds well in the milder districts or in well sheltered situations. Its habit of making late autumn growths renders it peculiarly susceptible of injury from frosts, by which the points, and sometimes the whole of the young

shoots, are destroyed. It is, notwithstanding, such a distinct and handsome species, that it should have a fair trial wherever a favourable situation is at command. As it thrives well in the shade, it is found useful for clothing walls or other buildings with aspects in which, from want of sun, few other Evergreens or flowering shrubs would succeed. It requires a dry porous soil and a warm subsoil. I met with some very fine bushes of it the other day, the largest, in fact, I have ever seen growing in a garden in Sussex, near Chichester, where the soil is of a chalky nature, yet warm and well drained. —G.

THE BEST EVERGREEN BARBERRIES.

Now that the planting season for Evergreens is at hand, it may be well to direct attention to the best kinds of Barberry to plant, as they are so indispensable in every shrubbery. Of the many species of *Berberis* in cultivation, which number over half a hundred, only about half a dozen amongst them are what may be termed really handsome shrubs, and although they differ widely in structural peculiarities, many of them possess a striking resemblance to each other. The genus is divided into two sections, the *Berberis* proper and the *Mahonia*, which sometimes ranks as a distinct genus. Among the true Barberries a few are really beautiful shrubs. The finest, no doubt, is *B. Darwini*, first discovered by the late Mr. Charles Darwin in Chili, and than which no more beautiful hardy shrub exists. This species is now too well known to need description. This year it has been very beautiful, the winter having been favourable to it, though even this season it has not been so fine as it was in the spring previous to the two disastrous winters of 1879 and 1880, which crippled it severely. Being a native of Chili, it will not stand any great degree of cold, and it is all the better for a mild spring. Next to *Darwini*'s Barberry in point of beauty is *B. stenophylla*, a garden hybrid between *B. Darwini* and *B. empetrifolia*. The long slender branches of this Barberry droop gracefully on all sides, making the bush, when profusely laden with blossoms, look like a fountain of molten gold. It is, moreover, a shrub that is not at all fastidious as to position, for it grows in shade as well as exposed, but it flowers most freely when in a good light soil in a warm, sunny situation. It is much hardier than *B. Darwini*, and seldom suffers from severe frosts. *B. empetrifolia*, though a fine shrub, is not equal to either of the preceding in point of floral beauty, but its habit of growth is elegant and it is very hardy. *B. dulcis* and *buxifolia* need only be grown where a variety of Barberries is required. Of the *Mahonia* section the commonest and most useful is, of course, *B. Aquifolium*, perhaps the most beautiful of all evergreen shrubs. As it is, or ought to be, in every garden, there is no need to describe it. Similar to it, but different in foliage and dwarf in growth, is *B. repens*, which makes a capital margin to larger groups. Less common kinds are *B. glumacea* and *fascicularis*, but they are not so desirable as *B. Aquifolium*. Even without reckoning the many varieties of the *Mahonia* section which are more or less rare, there is quite a wealth of beauty in the evergreen Barberries alone, and they can be obtained cheaply in nurseries. —W. G.

Hedges of False Acacia.—When the common Hawthorn cannot be got to grow as a hedge in dry arid soils, where one often sees the most miserable of stunted Moss-covered fences, common *Acacia* should be planted; it will thrive in such soils, and quickly form a strong fence. In very moist situations, in which the Thorn is equally a stranger, good fences may be made by planting Willows. The Willow rods should be crossed lattice fashion, as then a denser hedge is made in quicker time.

The Golden Arbor-vitæ.—The variety known as *Thuja occidentalis aurea* is a fine form of a well-known and one of the hardiest of all Conifers. It has a robust growth, an upright habit, and a suffusion of golden colour over the foliage. In autumn it

assumes a bronzy hue, and gradually changes to a golden one, retaining this till late in spring. The variegation being of a partial character, it does not decay in parts like the various variegated Conifers in which portions of the shoots are wholly blanched. —G.

Cupressus Lawsoniana filifera.—Like the intertexta variety, recently described, this is an extremely graceful variety, quite distinct from the various beautiful forms of the Lawson Cypress, inasmuch as it throws boldly out slender, undivided, drooping branches to a length of nearly 2 feet. In the second season of their growth these become tasselled at the points, and again throw forth slender branchlets—a peculiarity which will make it one of the most desirable and picturesque of evergreen trees. —W. G.

The Japanese Kerria.—The double-flowered variety of *Kerria japonica* is common enough, being a familiar shrub even in cottage gardens, but the single-flowered form of it, though a very pretty shrub, is uncommon; indeed, in but few gardens can it be seen. The variegated variety of it is also a charming plant, as everyone will admit who has seen the plants of it in full bloom—dense bushes covered with golden blossoms intermixed with silvery foliage. It is, however, decidedly less hardy than the double variety, and it is only as a cool greenhouse shrub that it develops its real beauty of foliage and flower. The major double variety and the variegated single variety of *Kerria* or *Corchorus japonicus* are well worth attention. —G.

Prunus triloba.—This delightful shrub will soon be bursting into a glow of coral-red buds and rosy pink-rosetted blossoms under the influence of the present mild weather, and a more beautiful sight in the spring garden cannot be found, and it is to be regretted that one only finds it in botanical gardens or in the best nurseries. As a standard it forms a low bush 3 feet or 4 feet high, and produces before the leaves appear fine, large, double, pale pink blossoms; the leaves are somewhat large, wrinkled, and of various shapes, some being broadly oval, with three acute lobes towards the apex, while others are oval and free from any lobes, but they are all coarsely serrated on the edges and bright green. It is a native of the north of China and quite hardy, but suffers from the spring frosts when in bloom and planted in the open border. It is seen to the best advantage and really thrives best when grown against a warm wall and pruned and trained as a Peach tree, except that, instead of every little shoot being nailed close to the wall, they should be allowed to hang free, as they are then most beautiful when wreathed with bloom. It has been named *Amygdalopsis Lindleyi* by a French writer. It is a very beautiful shrub. —W. G.

Insects on Peach trees (H. G. Bunnister).—The insects on your Peach tree are the Vine scale (*Pulvinaria vitis*). Brush the parts attacked by the insects with soft soap and water, and then scrape them with some blunt instrument, or rub them well with a stiff brush, to remove the insects and their eggs. Then dress the shoots with $\frac{1}{2}$ lb. of soft soap, 1 lb. flowers of sulphur, $\frac{3}{4}$ oz. of black pepper, boiled in 4 gallons of water for twenty minutes, thicken with lime until of the consistency of paint; or, sixteen parts of kerosene, three parts of condensed milk, and six parts of water: mix the milk and the water together before adding the oil; then churn until the whole solidifies, add fifteen times its quantity of water and use at once, or the butter rises and the solution is imperfect. —G. S. S.

HEREWITH I enclose some leaves of Marguerites, which are, as you will see, affected with something like the Celery fly. Can you give its name? Also a hint how to destroy it. Our plants are large, 3 feet to 4 feet through, and were in perfect health before this visitor put in an appearance. Kindly reply in your next issue of THE GARDEN. —T. WEAVER.

Your Chrysanthemums have been attacked by the grubs of a small fly (*Phytomyza albis*). Pick off all the infested leaves and burn them. If the leaves are held up to the light, the position of the grubs will be clearly seen. —ET.

I FORWARD a few tiny insects which I should be glad if any of your correspondents could identify. I should like to know their name, and if harmless. They have been very plentiful in the hair seating of my sitting-room furniture. What means could be used for their eradication? —HELVETIA.

* The small insects you forwarded for examination are

mites. They probably feed on the hair or wool with which your furniture is stuffed. The best remedy would be to remove the stuffing and bake it thoroughly. I do not think any fumigation would reach them, and liquid insecticides would give more trouble to apply than baking. —G. S. S.

SOCIETIES AND EXHIBITIONS.

CRYSTAL PALACE.

MARCH 26.

THIS, the opening show of the season, held last Saturday, was rendered very attractive by the miscellaneous groups of spring-flowering plants, comprising the *Narcissi* sent by Messrs. Barr & Son, Mr. Thomas S. Ware, and Messrs. Collins & Gabriel. *Cyclamens* were also well represented by fine collections sent by Mr. Odell and the St. George's Nursery Company (Mr. H. B. Smith, manager). The *Hyacinths*, *Tulips*, *Narcissi*, &c., staged by Messrs. H. Williams & Son and Mr. H. R. Wright were also very good. Messrs. Paul & Son exhibited a beautiful group of *Roses* and alpine plants, notices of which were made last week in the reports of the Royal Botanic and Royal Horticultural Societies' meetings. Mr. Rumsey, Joyning's Nursery, Waltham Cross, staged a very meritorious group of standard and bush *Roses*, noticeable being *Duc de Montpensier*, a highly-coloured variety; *Madame Montet*, pink, a fine full flower; *Prince Camille de Rohan*; *Madame Gabriel Luizet*, pink; and *Magna Charta*, a large full flower.

Messrs. John Laing & Co., Forest Hill, staged a very pretty group of *Orchids*, intermixed with *Palms*, *Asparagus plumosus nanus*, and other fine-foliaged plants. Worthy of note among the *Orchids* were fine examples of *Cattleya Trianae*, *Dendrobium Wardianum*, *Angraecum citratum*, *Dendrobium crassinode*, and several others. A fine plant of *Clematis indivisa lobata* was also conspicuous; as also a variety of *Imantophyllum*, named *sulphureum*. Messrs. Laing also exhibited a basket of beautiful blooms of *Marchal Niel Rose*.

Messrs. Cheal & Sons, Crawley, sent a collection of a hundred varieties of *Apples*, very good for the season. Conspicuous were *Sturmer Pippin*, *Beauty of Kent*, *French Crab*, *Claygate Pearmain*, and *Leathercoat Russet*, an unevenly-formed, dark russet variety.

Messrs. Wood & Son, Wood Green, and the Horticultural Company, Tunbridge Wells, exhibited samples of their manures and horticultural requisites.

In the class for *Cinerarias*, Mr. James was an easy first with large, well-grown specimens, measuring about 2 feet in diameter, the individual flowers being large and of fine form.

Messrs. Paul & Son staged the only group of *Amaryllis*, conspicuous being a fine dark variety, named *Lord Wolseley*.

First-class certificates were awarded to the following plants, viz.:—

Rose Princess Beatrice, a Hybrid Tea, with flowers of a creamy yellow, the flowers when young with a slight shade of pink; this will no doubt become a very useful variety. Shown by Mr. Bennett.

Cineraria Monarch, a large, dark, purplish violet variety; *Blue Bonnet*, distinct blue edges and white centre; *Stella*, purple, with narrow white disc; *Dante*, a very large flower, the outside of the petals purple shaded with magenta, the centre white; *Admiration*, white with lilac-shaded edges. All shown by Mr. James.

Imantophyllum sulphureum, a bright-coloured variety. Shown by Mr. John Laing.

Brownea coccinea hybrida, a bright coloured variety of this uncommon, yet when in flower very handsome, class of plants. Shown by Mr. Head, garden superintendent.

Cyclamen Royal Jubilee, a dark purple variety. Exhibited by Mr. Odell.

A detailed prize list will be found in our advertising columns.

WILL any reader kindly give in these columns the treatment of *Vallotas*, so as to produce large plants as sometimes seen at exhibitions?—ONE ANXIOUS TO GROW THEM.

I SEND you a photograph of a house with a specimen of *Clematis indivisa*. It does not do it justice, but it gives

some idea of its exquisite beauty. I have too in full bloom in the same house an *Akebia*, and its rich chocolate blooms contrast well with the white of the Clematis.—REGINALD KELLY, *Kelly Linton, Devonshire.*

A charming idea. The reduction of the photograph would be so great to suit our purpose, that we are unable to engrave it. Perhaps Mr. Kelly may one day have a smaller photograph done, of which, if suitable, we shall be pleased to make an engraving.—ED.

NOTES OF THE WEEK.

Frost report.—From a notice in our advertising columns it will be seen that Fellows of the Royal Horticultural Society can obtain copies of this on application to the assistant secretary, South Kensington.

M. Bergman—In reference to the testimonial to be presented to M. Bergman mentioned in THE GARDEN (p. 271), we note that all subscriptions may be paid to M. Chouveau, 84, Rue de Grenelle, Saint-Germain à Paris. The subscription list will be closed on May 1.

I SEND you a few coloured Primroses. They are now coming into flower fast since the snow cleared away. The high coloured Primroses are quite as early if not earlier in flowering than the common yellow one.—R. D.

A fine variety of this favourite flower, the flowers very highly coloured.—ED.

We have received from the director of the Royal Botanic Gardens, Kew, the March number of the Bulletin of Miscellaneous Information, containing notes on fibre plants, and dealing with the fibres derived from plants yielding what are known in commerce as Sisal Hemp, Manila Hemp, Bowstring Hemp, and Mauritius Hemp.

Cinerarias.—We have received from Messrs. Oakshott and Millard specimens of the flowers of their strain of improved large-flowering Cinerarias.

The flowers sent were large, of fine form and substance. The colours also were very rich, more especially in the case of the purple-flowered varieties.—ED.

Amaryllis Dr. Masters.—This variety has bold, showy flowers, which should render it popular with all lovers of plants. The flowers of this variety are upwards of 6 inches across, of excellent form and substance, whilst the colour is deep carmine-scarlet, entirely free from any tinge of green. We noticed this in great beauty recently at The Woodlands, Streatham.

Narcissus Ard-Righ or Yellow King.—This is now flowering here, from bulbs received from Mr. Hartland, Temple Hill, Cork. *Narcissus obvallaris* is also in flower. They are both growing under the same conditions as regards soil and situation. Bulbs of Ard-Righ received from Rev. Wolley Deol are not yet in bloom.—J. WALKER, *Whitton, Middlesex.*

Camellia Lady Clancarty.—From Mr. Gordon, Twickenham, we have received blooms of this pure white *Camellia*, in which the petals are curiously superposed. Mr. Gordon also sends blooms of a Japanese *Azalea*, named *hikae*, with flowers of a pale blue colour.

The *Camellia* on arrival had fallen to pieces, and we were unable to form an opinion regarding it. The *Azalea* was of a whitish lilac colour, and rather thin in petal.

Narcissus show.—The Scilly Islands Bulb and Flower Association held its annual Narcissus show on Tuesday, March 22, and, judging from the number of entries, 540 as compared with 360 of last year, it was a great success. The exhibits occupied 400 feet of staging. Mr. J. A. Dorrien-Smith, the proprietor of the Islands, contributed, not for competition, 162 varieties of Narcissi. All the flowers were grown in the open air.

Arisæmas.—These highly interesting plants belong to the Arum family; they abound in the moist forests of Northern India, in similar situations throughout the Indian Islands, and in various other localities. One or two kinds are now in flower at Kew, amongst which may be noted *A. præcox*, from Japan. This has trifoliate leaves, the leaflets of which are oblong-ovate with tail-like points, strongly nerved and deep green. The spathe is erect and rolled round the spadix at the base, the hooded part bending over the throat. The outside is conspicuously banded with bright green and white, the inner portion and the throat being purplish black. A speciosum comes from the Himalayan forests. In this the stems of the trifoliate leaves are green, mottled and banded with dull purple, somewhat resembling a serpent's back. The spathe is hooded, with the tapering point reflexed; purplish black within, striped with white; the spadix extends into a slender reddish purple tail some 18 inches or more long. Another species from the Philippine Islands which we recently saw in Mr. Bull's nursery at Chelsea has trifoliate leaves, and ovate-acute, deep green leaflets. The spathe is cylindrical at the base, the open portion being brownish purple, netted and streaked with white; the tip of the spadix is about a foot in length, densely clothed with long, purplish

filaments. Other remarkable and beautiful kinds are *A. concinnum*, from Sikkim, with a digitate leaf, and a large, hooded spathe, the upper part of which is very acuminate, and bent over the throat, alternately striped with bands of purple and white; *A. papillosum*, from Ceylon, with green spathe, banded with white; another Ceylon species, *A. Wightii*, having a light green spathe, banded with deep green, and the end of the spadix 6 inches long, erect, greenish white.—G.

British Primroses.—Mr. G. F. Wilson, of Weybridge Heath, charms us with his handsome British Primroses; they are later this year than usual, but still they are welcome on the last day of March. It is surprising what rich and varied colours these native Primroses show already. Certainly there are no other Primroses so good. Mr. Wilson also sends us some pretty single Hepaticas, of which we shall probably have more varieties than of old and the more the better, for they are hardly little things that, if they get a chance among low bushes, will always reward the planter.

Tinnea æthiopica.—This is a neat, bushy plant belonging to the Sage family. It first flowered in this country some twenty years ago, having been introduced by Mlle. Tinne, who gathered it during her Nile journey a few years previously. It is a compact, twiggy shrub, bearing somewhat ovate, smooth, deep green leaves, and attains a height of 5 feet or 6 feet, but commences to flower when not much more than 9 inches or 10 inches high. When young the flowers are produced singly from the bases of all the leaves on the upper branches, but as the plant increases in size and age the blooms are produced on long terminal spikes, and also on shorter ones from the axils of the leaves. The flowers are deep purplish maroon, and yield a grateful perfume, somewhat resembling that of Violets. We recently noticed this plant in Sir Trevor Lawrence's garden at Dorking.—G.

Azalea mollis.—A large group of this useful Japanese plant is just now very ornamental in Mr. Cutbush's nursery at Highgate, the colours ranging from soft primrose to yellow, orange, and reddish orange. This is a plant which well deserves the attention of those desirous to possess showy flowers during the dull winter months. They may be grown in the open ground during summer, lifted and potted in autumn, when the protection of a cold frame should be given them. If a few plants from time to time are placed in the cool stove a continuance of their showy flowers may be had from Christmas up to the time when the open-air plants expand naturally. There is a great variety in the colour of these plants, as they are reproduced by seeds. Some few, however, have been obtained by the Messrs. Cutbush, which are undoubtedly deserving distinction. Of these the most notable are The Queen, very compact in habit, with large pale primrose-coloured flowers; Lord Shaftesbury, rich golden yellow; Alphonse Lavallée, orange, shaded with scarlet and blotched with pale yellow; Consul Pécher, brilliant rose, blotched with orange; and Ernest Bach, pure salmon

Amaryllids at Holloway.—These plants have for many years been steadily worked upon by Mr. Williams, with the view of improving them in the colour, size, and form of the flowers. The numerous fine forms which have from time to time emanated from this establishment bear ample testimony to the success of these endeavours. Mr. Williams says Amaryllids are best potted just after they have done flowering, and the soil should be composed of three parts good turfy loam, one part leaf-mould with some sharp sand added. They should be placed in an intermediate house during the growing season, and treated liberally to water, and to liquid manure more sparingly. After growth is completed, the supply of water should be gradually decreased until it is entirely withheld, when the plants may be removed into a lower temperature, and stored away until required. Amongst the most notable kinds now flowering and contributing their quota to the spring show are Dr. Masters, a fine, bold flower, upwards of 6 inches across, the colour being wholly deep crimson-scarlet; Empress of India, rich crimson, flaked, and having a green base; Harry Williams, flowers very large, reddish purple, flaked with white; Joseph

Broom and Guiding Star are also two very fine forms; so also is Mrs. Rawson, deep reddish crimson, margined with white; Miss E. Holford, crimson, netted with purple, base light green, flaked with rose; Beana, crimson, veined with black, and a green centre; Dr. Bernardo, Marshalli, and many others.—G.

Marguerite Cloth of Gold.—I send for your inspection a few blooms of my new Marguerite Cloth of Gold. This is a chance seedling, raised by sowing seed from several varieties grown together. It can be had in bloom all the year round, and for cut blooms it lasts ten to fourteen days. It grows in pots from 18 inches to 24 inches high. Planted out, I have no doubt it would form a handsome bush and throw abundance of blossom.—ROBERT OWEN, *Mouthhead.*

** The flowers sent were large, of a very bright yellow, and no doubt will be much prized for cutting when their merits become known. A useful addition to this class of plants.—ED.

White Daffodils.—These certainly are worthy of notice when seen in all their beauty, as they are here at present—such lovely forms as Leda, Bishop Mann, Gladys, Colleen Bawn, Minnie Warren, Mr. Barr's tortuosus, and others. But the subject to which I wish to draw attention is the difference between Leda and tortuosus. The distinguishing character of Leda is the foliage, which is erect and narrow (not spreading, as tortuosus), of a glaucous colour on the surface, whilst underneath it is pale, amounting almost to white. The flower-stem is fully 18 inches long; the segments are white, and the trumpet comes out a beautiful cream colour, and in the course of a few days tones off snow-white.—Geo. HAGGERTY, *Tenple Hill, Cork.*

Imantophyllum miniatum at Holloway.—These plants are grown extensively by Mr. Williams, and the grand display made by a large houseful of specimens in bloom is just now a striking feature of the establishment. Many contend that the variations in size and colour here represented are simply brought about by good culture. This theory, however, is disproved by the fact of the typical plant which has been grown under the same treatment, and which may be seen flowering side by side with varieties which fully prove the inferiority of the type. These improved varieties have been obtained by Mr. Williams in various ways by cross-fertilising and selecting the finest forms arising therefrom, and by the introduction of various fine forms from Continental growers of this plant. A few of the most notable kinds now to be seen at Holloway are Meteor, cruentum, Martha Reimers, Baroness Schreder, Van Houttei, miniatum splendens, and Ambroise Verschaffelt. These are all remarkable for their large, dense heads of flowers, and for the size and colour of their individual blooms. The colour of all the varieties is orange-scarlet or orange-vermilion, with a yellow base of more or less intensity of shade; they vary also considerably in the depth and width of the perianth. These plants should be potted in somewhat rich sandy loam, and as they form large and thick fleshy roots, ample pot-room should be given them. They grow well in an ordinary greenhouse, but thrive best and flower most freely when treated to the warmth of an intermediate house.—G.

Names of plants.—*H. M. L.*—*Ornithogalum arabicum.*—*G. T.*—1, *Iris reticulata*; 2, *Collinsia verna*; 3, *Jasminum multiflorum*; 4, *Hepatica trilobata*; 5, double form of same.—*T. J.*—A flowering spray of *Asparagus plumosus.*—*Flora.*—1, *Sparmannia africana*; 2, *Habrothamnus elegans*; 3, *Correa cardinalis.*—*T. G. Bolton.*—1, *Lastrea decomposita*; 2, *Davallia filix-avis*; 3, *Arostichum aureum*; 4, *Trichomanes trichoides.*—*A. H.*—*Lycaste Hartsonae.*—*H. T. M.*—1, *Dendrobium Jamesianum*; 2, *D. crissalode*; 3, *Dendrobium filiforme*; 4, *Dendrobium linguiforme.*—*R. Smith.*—1, *Epiphyllum truncatum violaceum*; 2, *Selaginella viticulosa*; 3, *Blechnum occidentale*; 4, *Phymatodes peltica.*—*A. T.*—*Bacon.*—*Lycaste Hartsonae.*—*J. R.*—Cannot name varieties of *Camellias.*—*F. R.*—*Cymbidium sinense*; 2, *Lycaste gigantea*; 3, *Dendrobium Johannis.*—*Cap.*—1, *Leucodendron argenteum*; 2, *L. grandiflorum*; 3, *Erica Banksii.*—*C. H.*—1, fruit of the water Caltrop (*Trapa bicornis*); they are largely eaten in China.—*G. T.*—*Ripley.*—1, *Selaginella Lyallii*; 2, *Gymnogramma sulphurea*; 3, *Dictyogramma japonica*; 4, *Trichomanes crispum.*—*Ramsd.*—1, *Boronia megastigma*; 2, *Epacris pulchella.*

Names of fruits.—*R. Smit h.*—Pears not recognised.

WOODS & FORESTS.

"YORKSHIREMAN."

USELESSNESS OF TRENCHING FOR
TIMBER TREES.

THE following examples will show what little benefit arises from trenching the ground to the extent practicable in the case of forest trees. Almost everywhere near here the top soil is extremely shallow, just a plough's depth and no more. Below, the subsoil consists of brashy, yellowish rock, much disintegrated and loosened, but preserving the formation. Under this, a good many feet from the surface, but varying in that respect, comes the "bind," a blue clayish-looking shale that lies above the coal. It is in the upper strata that the trees grow, the brashy loose rock containing no soil in the proper sense of the word whatever. Some years ago in sinking for water this rock was found permeated with the roots of the timber trees to the depth of 10 feet and 12 feet, they having penetrated the seams in every direction. At one place an immense worm was found at that depth. There was no top soil worth speaking of; the trees grew in the rock above and drew their nourishment therefrom. Yet the trees grown in this poor stuff are large and healthy, from 100 to 200 years old, and consist of Spanish Chestnuts, with more than 150 feet in them; Beeches, a little less; Oaks, Walnuts, Ash, and Elms. To look at the subsoil, it is, perhaps, about as unlikely a medium in which to grow timber trees as could be found, but the facts are as I give them, and apply to almost the whole of the estate, which is well wooded to the extent of several thousand acres. Trees seem to have a far greater power of accommodating themselves to soils than vegetables. On several estates here, the "pit hills," as the mounds of blue bind or shale sent out of the pits are termed, have been planted just as they were with mixed collections, consisting of Larch, Firs, and the usual deciduous trees, all of which grow freely in material that cannot be called soil at all. We thinned the other week a plantation of this sort—cutting out the smothered weaklings for stakes and Pea sticks—that was planted about twenty-three years ago, and many of the trees are between 20 feet and 30 feet high. The Larch and Spruce do worst, but the deciduous trees seem as if they would make useful timber by-and-by. Curiously enough, however, neither the subsoil before mentioned nor this shale suit farm or garden crops, and whenever the subsoil has been brought up in either case in order to deepen the tilth the result has been bad for all kinds of surface crops, until the soil had been worked and manured for several years and incorporated with the surface layer.

FORESTRY MANAGEMENT.—Reverting to the growing of timber on those estates near the borders, the praises of which were sung at the forestry exhibition, and the results of which have been published under the title of "Timber-growing as an Investment," I am reminded that, although the plantations in question and many others of the same kind are mostly from 30 to 130 years of age and comprise Spruce and Scotch Fir, which would be easily and cheaply transported to the Yorkshire, Durham, Cumberland, and Scotch coalfields if necessary, yet the Norway Spruce poles hold the market, not a foot of home-grown Spruce being disposable for the same purposes, viz., pit props, which alone are imported annually to the value of hundreds of thousands of pounds. These Norway and Swedish props are, I am told, grown without any scientific management whatever, and at

such a quantity to the acre as would pay home growers on a scale they never dreamt of in their wildest moments of scientific enthusiasm. And why are these Scotch and border Spruces shut out of the market? Because they have been grown on a wrong principle, and are too rough and unsuitable for any purpose but wild pigeons building their nests on. I stumbled the other day on a small quantity of English common Spruce laid down for odd purposes at 5d. per foot beside a pile of Norway props delivered on the same spot at 9d. per foot, and which foresters in this country could get for the same if they could grow them. I was so struck with the contrast between the two samples of the same kind of timber—the one, an example of English forestry management, and the other, of Nature's management—that I fetched two props away with me, and I have them now drying in my office, and I purpose sending them to your office for you to see, after which you might try the two as firewood.

USEFUL FENCES.

SPRUCE HEDGES.—In Northern England, at least, these are not at all common, but travel through some, indeed most, of the Scotch counties and you will see them in abundance, every farmer knowing well how admirably adapted the Spruce Fir is as a shelter-giver to his house and steading. Perthshire, in particular, abounds with beautiful, well-kept Spruce hedges—hedges, or rather wind barriers of from 20 feet to 30 feet in height, evensided from repeated and careful pruning, and in every way well fitted for the important purpose intended.

At first, the young Spruces are planted at 4 feet apart, and after a few years every alternate one is taken out, the remainder headed down or deprived of their leaders, thus inducing a bushy, stunted habit of growth, and well-branched stem down to the very ground surface. Every year afterwards a certain length of the topmost shoots is removed, until the fence is of the desired height, when all it requires is an annual cutting or trimming of the side branches. Thus treated, it is wonderful how dense and thick the fence becomes, and what an amount of shelter it affords is just as surprising. At a distance, a well-kept Spruce Fir hedge cannot be distinguished from one made of Yew, the foliage, colour, and density of growth being almost akin in both plants. The poisonous qualities of the Yew quite preclude its use for farmers' fences, else no better plant as a shelter-giver can be found; but the Spruce Fir has several qualities that justly entitle it to fill the place of the latter, such as the great height to which it can be trained as a hedge plant, the amount of shelter it affords, as well as the remarkably pleasing appearance it presents when well managed and kept in bounds. Few soils come wrong to the Spruce—wet or dry, loamy or peaty—indeed, it has, as a hedge plant, special peculiarities in this way, for even in water-logged ground it grows away quickly, and puts on a richness of colour that few other plants can imitate.

ARBOR-VITE HEDGES.—Perhaps there are few evergreen plants that are not adapted in some way or another for the formation of live fences, but some are decidedly superior to others, and the American Arbor-vite may be ranked in the latter class. To those who have only seen the plant under notice as a straggling, limp-branched standard specimen the above recommendation may seem somewhat out of place, but "seeing is believing," and I had the satisfaction not many days ago of being shown as nice and densely compact a hedge of this Arbor-vite as any hard-to-please gardener would care to see. The plants had been placed about 15 inches apart and in single line, the ground being well prepared previously by deep digging and enriching with nursery compost. At present the fence is 5 feet high, and in shape a round-shouldered wedge of

barely 2 feet through, as dense and strong as could be well desired, and with a pretty bronzy green tint that one does not meet with in live fences every day. I do not think that I would recommend such a plant as this Arbor-vite for the formation of farm fences, or of those to which cattle would have access, but for a screen fence in ornamental grounds, such as on the lawn, in the home nursery, or similar places it has certainly all the good qualities that are necessary for hedges in such places. Trimming and pruning it bears well—better, indeed, than a person who is well acquainted with the plant as a standard would be led to infer. Another useful Arbor-vite that one unfortunately sees far too seldom is a variety of the above, named *Vervaeana*, a dense, upright-growing tree with light green, almost golden, foliage, and a remarkably robust constitution. For hedges it is even preferable to the species, having a far more fastigate habit of growth, being of less size, and in colour of foliage decidedly preferable. It stands rough winds in a very satisfactory way, grows vigorously in either peat or loam, is of easy nursery management, and bears the pruning-hook or shears with impunity.

GORSE HEDGES.—How seldom we see the Gorse treated in anything like a proper manner, either for underwood or as hedges. For planting on dry ridges raised a little above the general level of the ground and in high-lying districts it is particularly well adapted, but to preserve it in anything like a satisfactory condition either as a fence or for covert purposes, yearly cutting over of the plants must be attended to. By cutting the Gorse plants over in early spring they soon send up abundance of shoots that are clothed to the ground with a dense green growth, this latter being wanting entirely in old plants, and which gives to them such a lank, bare appearance, and renders them quite unsuited either as a fence or for covert purposes. To raise hedges or banks of the Gorse is simple indeed, for all that is required is to sow good seeds in spring, and by the following season a dense growth of young plants will be observable all over the surface. We frequently, when forming plantations at high elevations, prepare a strip of ground—say a couple of feet wide—all along the line of fence that surrounds the wood and sow Gorse seeds upon it, and when the plants have attained to 3 feet or 4 feet in height they afford a wonderful amount of shelter to the young trees as well as impart a clothed appearance to the exterior of the woodlands. In preparing the ground in such situations little expense or trouble need be expended, all that is necessary being to dig over one spade deep along the intended line of fence, level the surface with a rake, and sow the seeds. No weeding is usually required, for the dense growth of the young plants is sufficient to kill out any rivals in the shape of Grasses, &c. By thus forming a screen or belt of the Gorse around the wood seedlings soon spring up all over the interior, but principally in such places as an abundance of light and air is admitted to, and thus underwood is cheaply and effectually got up.

A. D. WEISTER.

Destroying stumps of trees.—The following recipe is reported to have proved very successful in the backwoods of America: In the autumn bore a hole 1 inch or 2 inches in diameter and 18 inches deep, put in 1½ oz. of saltpetre, fill with water and plug up close. In the following spring put in the same hole half a gill of kerosene oil, and then light. The stump will smoulder away without blazing, even down to every part of the roots, leaving nothing but ashes.

Hedges are undoubtedly going out of fashion everywhere. At one time they were preferred to dry walls on gentlemen's estates because of their more ornamental appearance, but a Quick Thorn hedge, however well trimmed, is not now regarded as the most useful, the cheapest, or the best looking fence. On farm lands fences of some kind—it does not matter much what—will always be necessary; but in parks around mansions the tendency is to abolish fences altogether, or at all events to keep them out of

sight as much as possible. Some years ago it was suggested to a nobleman, who took much interest in planting and landscape gardening, that the prospect in many instances was marred by the trim hedges which enclosed even the smallest patches of wood or copse from the parks, giving a stiffness and formality to the landscape which was noticeable even by those who did not always detect the cause itself. Wherever possible the hedges were removed in time, and strained iron fences substituted instead with the most marked improvement. At a distance these fences were hardly noticeable, and the absence of visible barriers tended to give a much opener and more natural aspect to the landscape.—S.

PARK AND OTHER ROADS.

THE remarks in last week's issue on park roads by "J. S." were very good, and if they are followed by all those who have roads to make, I am sure the estate roads of the future will be far better than many now used.

Following "J. S.'s" instructions, a few remarks on the materials suitable for covering roads may not be out of place. The following is an enumeration in order of fitness, with the specific fitness of each for the purpose:—

1. *Green whinstone* is undoubtedly, of all other materials, the best adapted for the covering of roads. It combines great hardness with toughness; it breaks with clean, solid angles in its fracture—a property which adapts its particles for binding into a solid mass with a smooth surface. This stone, when of the right variety, possesses every property for forming the best and most durable road covering. There is, however, a variety of whinstone or basalt of a very dark colour which, although very hard when quarried, speedily disintegrates into a soft, powdery substance by the action of the atmosphere, and is, therefore, unfitted for the covering of roads subject to heavy traffic.

2. *Granite*, equally as tough, if not tougher than the best whinstone, is coarser in texture, not so hard or the fracture so clean as whinstone, from which it will readily be understood not to have an equal property of binding into a solid mass with so smooth a surface as whinstone.

3. *Flints* are extremely hard, but deficient in toughness, and therefore easily break down into sand under heavy traffic, although, to the extent of their durability, they form a smooth surface when properly prepared.

4. *Limestones*.—With the exception of soft chalks, which are unfitted for the covering of roads, all bind well into a smooth surface; but all being affected by atmospheric action, even the hardest is less durable than any of the materials previously noticed.

5. *Gravel*, by which term is to be understood the mixture of various sizes and descriptions of water-worn stones, frequently found in beds of various thicknesses near the surface of the soil. These, of course, partake in their leading properties of the character of the nodules which mostly prevail in the mixture. When the gravel is clear of soil, and the nodules of a homogeneous character—which is seldom the case—broken into angular pieces, it frequently makes an excellent and durable covering for roads.

6. *Sandstone* has its particles too slightly cohering for the purpose of road-making where there may be a considerable amount of traffic. It is, however, a most suitable material for the pitching or rough pavement for underlaying the surface when a road is so constructed.

Besides the natural stones noticed above, the slag from the smelting of iron ore makes excellent roads in summer and in dry weather; but, it being frequently a soluble silicate of lime, it generally dissolves into viscous mud in winter and in wet weather. In order to avoid the expense of cost of carriage, the material for road-making will generally be what can be obtained in the neighbourhood of the road to be made.

A matter of much importance in road-making

is that hard and soft materials should never be used in mixture, but should be used in separate strata or in different parts of the road, for the harder crushes the softer when used together, and causes the road to be more speedily worn than when it is made entirely of soft material. It is best when circumstances compel the use of a portion of soft material, or of materials of different degrees of hardness, in the construction of a road, to spread the softest in the lowest stratum, and the hardest at the surface, using that of intermediate quality between. A. T. PATERSON.

Grafting Conifers.—The grafting of choice Conifers may be performed early in spring or about the month of August. For this purpose two-year-old stocks are preferable, as it is desirable that the stock and scion should be as near of a size as possible. They should be established in 3-inch pots, and if it be intended to use them early in the spring they should be kept during the winter in cold frames. There are several methods of grafting Conifers, but ordinary side-grafting is in most cases the best. This operation consists in making a clean cut in the stem downwards about an inch in length, then at its termination making a transverse cut, thus removing a piece of the bark-wood clean away from the side of the stock. The scion should be cut off clean and square at the end, and a piece of the wood should be shaved off about equal in length to the cut on the stock. The butt-end of the scion should then be placed upon the notch cut in the stock, taking care that the bark on one side meets exactly the whole length of the cut. The great aim in this operation is so to cut the scion and stock that the former when fitted on nearly replaces the piece removed. The scion being thus fitted must be held firmly in its place by the thumb of the left hand and tied on with bast or wool so that it does not afterwards shift. When the scion is very small, or the stock much out of proportion to it, another method may be practised. This consists in simply making an incision obliquely in the stock, the scion being so cut that one side of it forms a sharp edge, in order that it may be easily inserted therein, the bark of the scion thus coming level with that of the stock. This is a neat and expeditious method, as when united it is difficult to perceive the union. The cuts must be cleanly made with a sharp knife, and the incision in the stock and the cut on the scion should correspond in length as nearly as possible. This latter method scarcely needs tying, as if properly done the scion will not easily move, and it quickly unites to the stock.

How wood is made.—In many trees the annual layers are so regular, and seem to be placed so nicely, that one not a botanist might be pardoned for believing that the sap was changed to wood matter in the leaves, and the new-formed matter sent down, sliding over the old layer like the section of a telescope; but, though the food was prepared by the leaves in a great measure, the actual growth was made by the germination of some of the cells along the whole outside wall of last year's wood beneath the inner bark. The germination of the cells takes place about the middle of June. Take a healthy Cherry tree and strip it entirely of its bark to any length desired. At that season a viscid liquid will be found covering the woody surface in abundance. The stripped part is covered with a cloth to prevent evaporation, and in a few days numerous dots, like needle points, will be seen about the sixteenth of an inch apart all over the surface. These are the young cells which have germinated from those of last year. They continue germinating, one from the other, until they meet, when they unite and form a complete surface. In the autumn a layer of wood will be found just as thick as in the part of the tree not disbarked, and a single layer of liber, with its outer coat of cellular matter—perfect bark—will have been formed over the whole. The entire formation of wood and bark can thus be seen by the ordinary observer without the necessity of any nice microscopical work. Other people have tried the experiment with other trees. We have seen large Apple trees that have had their bark peeled wholly off from their trunks, at the season named, make an entire new layer of bark and

wood, not only with no injury to the tree, but to its manifest enjoyment; but our own experiments were confined exclusively to the Cherry. By this experiment we learn that there is no difference primarily in any part of the annual covering. The same cell may become permanent tissue or generative tissue, and from the generative tissue may come, before the season of growth closes, every form of structure known to anatomists, from pure wood to the outermost cuticle of the bark. How these cells become differentiated may be passed over here. We know that cell-growth is not always uniform in its operations. The law that changes the outermost series of newly made cells into liber need not necessarily operate so exactly as to make them perfect to this end—a few may be thrown off into the liber as generative tissue—and, granting this possibility, we see how the woody granules in the Apple are formed.

SEASONABLE WORK.

FINISH thinning plantations before the buds begin to expand, as a sudden admission of cold air to a plantation after the trees have commenced leafing is injurious, especially to Larch growing on exposed situations at a high elevation. Arrange felled timber into lots, each of which should be numbered and valued, and the particulars recorded in the forester's note-book which will be useful as a reference at the time of sale. Finish planting deciduous and other trees on dry situations as soon as possible, if not already done. Peat bog and soils that retain excess of moisture, and are apt to swell by frost and eject the plants, may be successfully planted at the end of March and beginning of April. Examine all recently-formed plantations, and have all failures and vacancies carefully re-planted, and in doing so extra care is necessary at this season not to expose the roots to the influence of drying weather.

In favourable weather finish the sowing of seeds of all deciduous trees. Plant out seedlings into nursery lines, and transplant the stock to be retained in the nursery for another year, which will encourage the formation of fibrous roots; such plants as are not to be removed should be dug between the lines in order to keep down weeds and stimulate healthy growth. Dig and prepare ground for seed-beds of Conifers, and in places where the ground is poor and exhausted, a dressing of vegetable mould or well-rotted manure may be applied with advantage.

Nursery ground that has carried a succession of trees for a number of years, and thereby become exhausted, will be much improved and renewed by planting it for one year with Potatoes or Turnips, which is the best preparation for ground to be sown with tree seeds in autumn. In favourable weather commence to graft those kinds of forest and ornamental trees usually propagated in that way. Gather seeds of the common and hybrid Rhododendrons, and in places where the latter have been growing in groups of different kinds and colours, the seedlings raised from their seeds often produce new varieties which are more attractive, and much more valuable than such as are raised from the seed of the common *R. ponticum*.

Clean drains where necessary, and collect the leaves in heaps to rot, which will be useful as manure. As March and April are the best months for drying and seasoning timber, no time should be lost in having a suitable quantity cut up into boarding, planking, and scantling of different sizes for the requirements of the estate. Examine and mark Oak trees in forest, field, and park that are to be removed, so that there may be no delay when the barking season commences. Secure trees so as to prevent wind-waving, and mulch such as have been recently planted. J. B. WEBSTER.

SHORT NOTE.—WOODS AND FORESTS.

Trees to succeed Scotch Fir.—What kinds of trees would be most likely to succeed if planted after the Scotch Fir, and without the ground being cleared? The situation is high and exposed.—S. N.
Beech, Sycamore, and Ash will form as good a succession to any of the Fir tribe as can be found; these are three quick-growing and profitable trees, and none stand exposure better. They attain to large dimensions, 1200 feet above the sea in Yorkshire, fully exposed. Plant thick.—YORKSHIRE MAN.

No. 803. SATURDAY, April 9, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare*.

FRUIT GARDEN.

W. COLEMAN.

THINNING FRUIT BLOSSOMS.

A CORRESPONDENT says the thinning of the flowers on Peach trees is not so much practised as it might be. Why is this important operation neglected? It is not new, for I learned it many years ago from a very old friend, who, nearly a century ago, was forcing foreman at Woburn Abbey. It is not unknown, as I have frequently advised readers of the calendar to rub off all the pendent blossom buds before they open. Vigorous trees in the heyday of their youth do not require this attention; in fact, they often set best when all the flowers are allowed to expand, but once settled down into a thoroughly fertile condition, it is not unusual to find them producing 80 per cent. more flower-buds than are needful for the crop of fruit. Heavy cropping, poor soil, unkind stocks, one or all check the growth of wood and favour the formation of flower-buds. These often set as thickly as Peas in a pod and swell to a certain size, when the weakest make a dead stand, and those produced from the finest and strongest flowers push forward, and are selected as the fittest. Thinning in accordance with ordinary practice is then commenced, and although there prevails an impression that flowering and setting does not weaken the trees to any serious extent, the fact that the fruits left on the shoots at once start away with a rush goes far to prove that their size and safety might have been increased by thinning off the inferior blossom-buds. To disbud a set of large Peach trees as plantsmen disbud their Roses and Chrysanthemums would be a ponderous task, which few might care to undertake, but this method I do not consider necessary, as the removal of the two guard buds from all triples would involve much care and patience. Floriferous Peach trees under glass produce complete whorls of buds from 1 foot to 2 feet in length, those on the upper sides of the shoots being most valuable. These I always leave intact, but remove all pendent buds by drawing the finger rather sharply down the undersides of the shoots as soon as they begin to swell. By this means probably 30 per cent. of the least valuable flowers are taken, and the frequent temptation to leave a promising drooping fruit whose point could never colour is avoided. Wall Peach trees do not often receive, although they would be the better for this attention, particularly when they become aged and produce a predominating number of blossom-buds. Many of the new, especially the large-flowered, varieties do not, however, produce a damaging profusion of flowers; why this is so it is difficult to say, as it is hardly possible the first remove from their sturdy parents can have made any perceptible difference in their hardiness; and yet some of them, notably Early Grosse Mignonne and others of its race, are apt to get more or less cut during sharp winters. Few Peach growers ever saw the old Noblesse or its offspring, the Alexandra Noblesse, overloaded with flowers, and yet they seem to enter into the winter carrying a plentiful crop of silvery buds. A few only of these survive the mildest seasons,

but fortunately those that do escape the frost or damp invariably set well—a fair proof that floriferous sorts may be freely thinned not only with impunity, but with advantage to the health and longevity of the trees. Plums, Pears, and Cherries are difficult subjects to deal with, and yet I have no doubt bud thinning, especially on wall-trained trees, would lead to equally satisfactory results, as we invariably find trees that have set profusely thinning themselves sometimes to an alarming extent. The first and last, in forcing houses and all three on walls, in course of time become one mass of spurs with hardly a wood bud to draw the sap, and although we cannot well undertake the thinning of the buds on each individual spur, we get over the difficulty by cutting out a quantity of the oldest spurs bodily at the winter pruning. Whoever has been engaged in the forcing of Plums and Cherries knows how necessary it is to use a fine-bladed knife amongst the trees, especially where they are grown in pots, and they will corroborate my statement that liberal spur-pruning, which is bud thinning on the broad gauge, is antagonistic to insects, whilst the flower-buds left on the trees are bold and strong and invariably set well. This practice might, no doubt, be carried out with great advantage upon many fruit trees of moderate size in the open air. Pears, for instance, on the Quince, and Apples on the Paradise stocks, which literally flower themselves if not to death, certainly to premature old age, might be so treated, and I question if the fruit would not be much finer and the trees more vigorous than others which are allowed to expand all their blossoms and cast their fruit by the thousand. Last year I took five out of every six fruit off a Stirling Castle Apple as soon as they commenced swelling, but I was too late, as others which had been bud-thinned were much finer, and showed no signs of self-thinning. Many large growers cannot perhaps spare the time, but those who can and wish to have extra fine quality may safely try this plan.

GRAFTING AND INARCHING VINES.

MR. IGGULDEN deals so well with this subject, that I hesitate in sending a few lines describing what I have done in this way, especially as I am not quite in accord with him. Without doubt any Vine will be benefited by either grafting or inarching, and if I had a Vine of any kind subject to shanking for instance; by inarching, even without cutting back the old scion, I could secure a marked improvement the following year. Again, supposing I graft or inarch, say, at 2 feet or 3 feet high, the Grapes below the graft will be good. I have demonstrated this here so many times, that it is now well known. Now for a few lines on varieties. Muscats are the only stocks I have used so far for inarching. As for the most noble of all the black Grapes—Gros Colmar—all who have tasted this so worked admit that flavour is gained. Colour, again, is good, unless I overweight with crop. Foliage is much stronger and not so given to curl. In no one case do I find Muscats shank below the graft. I should say this stock is used by me because I am gradually reducing Muscats, the Gros Colmar being more profitable. I used one Gros Colmar to graft Madresfield Court with very unsatisfactory results, flavour being all gone, without any increase of size in berry. Last summer I inarched a Gros Colmar on Barbarossa, and shall look forward with interest to the result.

Hamburgh I have used largely for grafting on Alicante, which does well; the mistake I made

last year was in the heavy crop (18 bunches, 40 lbs.) on one-year-old rods, besides having a few Hamburgh bunches below the union. I was afraid the stock would be against its keeping; but, no, it is all right; however, I hope by lighter cropping to have finer Grapes this season. Hamburgh as a stock for Gros Maroc (a Grape which for early autumn up to Christmas for selling has no equal) makes a very great improvement in flavour, and the berries are large, but their shape is somewhat altered. Buckland Sweetwater I have used for Alicante and Gros Maroc, and this is undoubtedly the best stock for these two Grapes. My best Gros Maroques were grown on this stock.

While I am writing these few lines from a market point of view, I trust I have not lost sight of my taste for quality. So much could be advanced from my side of the question—that is, improvement—but I fear to say more. It would be folly for me to run down the high quality of Lady Downes; but notwithstanding I get a good crop, neither weight nor price are equal to Alicante, which is much behind Gros Colmar. I enclose photo of crop of Lady Downes.

Scald, I am thankful to say, does not trouble me; this in the majority of cases can be avoided by ventilation, though excess of moisture, low temperature, and allowing the Grapes to steam will often cause it. Some people say that this is a disease; if so, it may be prevented. Again, some affirm that the sun is the cause; this is not so, though it may be brought about by the sun shining forth suddenly, more especially after a dull time. I suppose two dozen berries would cover my losses for last year from this cause, and in no one case was there one berry that the sun could touch by shining on. These scalded berries were in the shade, and were generally touched on the north side. I think before coming into bloom that a rise of temperature with increase of ventilation is necessary, and this rise must be maintained until the time when the fruit begins to colour. As soon as scalding is detected, more fire and ventilation should be given, and a little chink of air may be left on at both top and bottom with advantage during the night. Foster's Seedling, highly praised though it is, is not equal to Buckland Sweetwater, although the former is the white Grape for this locality, and I see every year very heavy crops of fine fruit grown and sold for 9d. per lb. With me, growing with Muscats, if it hangs any time after it is ripe the appearance is gone. I purpose using this variety for inarching Gros Colmar.—STEPHEN CASTLE.

— It is gratifying to me and satisfactory to readers of THE GARDEN to find an accomplished Grape grower like Mr. S. Castle corroborating all that I have recently said in favour of this excellent system, as his remarks go far to prove that I preach that which I practise. Knowing that the character of a viney can be changed in the course of a single season, nay more, that a set of fruit-bearing canes can be run up from bottles without sacrificing the crop, I was in hopes that my paper would induce the masses to try experiments upon a few surplus rods, as this is the only way in which the young beginner can gain confidence. One or two experienced Grape growers intimated that they gave preference to inarching, a method to which I did not think it necessary to allude, because it is as old as it is simple—consequently thoroughly understood by the veriest tyro in Vine culture. My leaving this method untouched must not, however, be misconstrued, as I look upon it as the best and safest mode of introducing new or fresh varieties, especially when the young wood is very small, over-worked, or in a growing condition. The white Gros Colmar, for instance, which is to be sent out during the coming summer, will no doubt

be worked by many as soon as it is received, and I shall certainly adopt this method. But if I could have button-holed Mr. Roberts, the fortunate raiser, I should have preferred paying him for a bottle-graft, and I venture to think Messrs. Nash, Castle, and other skilled workmen would have followed suit, that is provided they have a Muscat house in which they might wish to work it. Grafting I still maintain is a method imperfectly understood, but it can be learned without detracting from the older system of inarching, and I trust the day is not far distant when every British Grape grower will set about grafting a house of Vines with as much confidence as he now brings to bear upon grafting an Apple tree. As forced fruit producers we can defy the world; why should foreigners beat us out of the field as propagators?—W. C.

OUTDOOR PEACHES AT HOWICK HALL.

MUCH has recently been written anent outdoor Peach culture, but, like most questions, there are several sides to look at. In dealing with the subject many, perhaps too hastily, assume that Peaches cannot now be grown successfully outside; yet there is no doubt but that, although we have not had quite so favourable seasons of late, by careful management good Peaches may be grown in this way. We are informed that fifty or sixty years ago good Peaches were grown in many places where now they will not grow at all. "J. S. W." in THE GARDEN (p. 252), March 19, says that while the outside cultivator is fighting against frosts, mildew, blight, &c., the under-glass man is far in advance of him with a much better chance of securing a good crop. But where glass houses are not available and Peaches are required, open-air culture is the only alternative.

Even in the south of England I have not seen Peaches grown outside better than they are at Howick Hall, where, on the bleak coast of Northumberland, they have the cold east winds from the German Ocean to contend with. The Peach trees in question are growing upon a south wall, 150 yards long by 12 feet high, built of red brick. The wall is flued and is supplied with furnaces, but fire-heat is never used, with the exception of a fortnight in the autumn, when, if a cold and wet season, it helps to ripen the wood. The trees are well shaped and full of young wood to the bottom, and special attention is paid to them as regards keeping their roots in check, also in having them near the surface, which is undoubtedly the great secret in successful outdoor Peach culture. When in bloom—as at the present time—the trees are merely protected by canvas, which is rolled up in the daytime. Great attention is paid to summer pinching, thinning out, and nailing in the young wood, all of which are essential to the ripening and colouring of the fruit. Another important item is to keep the leaves free from red spider, aphid, and mildew, which, if allowed to increase, will quickly ruin the prospects of a good crop. The trees are thoroughly drenched on every fine afternoon, and by these means they are kept in a perfect state of health, and great credit is due to Mr. Inglis, the head gardener, who informed me that some years ago he gathered ripe Peaches from the wall the third week in July. As a rule the first fruit is gathered about the middle of August, and from that time hundreds of dozens of well-ripened fruit may be seen. Royal George, Acton Scott, Dymond, Prince of Wales, Princess Louise, and Sea Eagle are the principal varieties grown, Acton Scott generally coming in first, followed by Royal George and Dymond, the other varieties following in succession. All the sorts are well flavoured, with the exception of Sea Eagle, which, although it ripens fairly well, rarely attains flavour enough to fit it for the table.

I may also mention that on the same wall there is growing the noted Howick Fig, which is figured in Thomson's "Assistant." It is similar to the Brown Turkey, but appears far superior to that variety. It has been distributed over America under the name of the Howick Fig. The old tree covers a space of wall 60 feet in width by 12 feet in height. Although receiving no protection whatever during the winter, it bears annually a good crop of remark-

ably fine fruit, which generally ripens about the first or second week in September.

OLIVOR.

SHADING MUSCATS.

IN some vineries it is absolutely necessary to shade the foliage of Muscat Vines to preserve them in anything like a satisfactory condition throughout the summer and autumn. The need for this operation, in my opinion, is caused chiefly by the roots of the Vines not being in the best possible condition, owing perhaps to various causes. There may be too great a depth of soil in the border, and that of a nature not suited to this Grape. Roots cannot run so freely in a close, heavy, retentive soil as they will in a border composed of lighter material. Where the soil is of a tenacious character, it is a mistake to make the borders so deep that they require more than 2 feet thickness of soil; if the soil is light, 6 inches more in depth should be allowed. Some may say, why not add other kinds of lightening material, such as wood ashes, charcoal, and lime rubbish? A case came under my notice a few years ago. When taking charge of my present situation, one vinery, amongst others to be planted, was to be devoted entirely to Muscats. A large quantity of turf, varying in thickness from 2 inches to 3 inches, was cut. This was quite a mass of fibre, having lain undisturbed for over seventy years. It was chopped up into pieces about 3 inches or 4 inches square, and with it was incorporated a quantity of lime rubbish and half-inch bones, but no manure. The whole mass was trodden down firmly, the depth being about 3 feet, with a liberal drainage underneath and a free outlet for superfluous water. In due time the Vines were planted and broke strongly, making growths the first season over 20 feet long. The roots were liberally supplied with water during the summer and the Vines freely syringed overhead, their appearance being very satisfactory at the end of the season. The following December they were pruned back to three eyes above the first wire under the roof, *i.e.*, one pair of side shoots and a leader. These all showed fruit; one bunch to each cane was retained just sufficient to prove the variety. The following season they grew away very fast and bore a good crop of fruit, which finished well; but in May the next season, which was the fourth year of growth, the border was one morning thoroughly soaked with weak liquid manure, and about mid-day several leaves showed strong symptoms of having been scorched. This could not have happened through the usual cause—that of insufficient air, because, being a hot day, the house was freely aired, and had been so during the time the water was being used. The scorching continued as the season advanced and generally after the border was watered, which we did on dull days. This, however, availed little, as the scorching went on, and always when there was plenty of ventilation. The consequence was that the Vines were denuded of their largest and best leaves, which were of most service. The crop of Grapes too was large in bunch and the berries of fair size, but they did not finish off properly, and shrivelled early, almost as soon as ripe. Many were the opinions advanced as to the cause; but the right one was obtained by digging down into the border in several places and examining the soil. The fibrous part of the turf had decayed, leaving the whole quite an inert mass, excepting the part where the lime rubbish was used. Of course, the water, which had been freely given, was not able to pass so quickly away as would have been advantageous to the Vines, and it was clearly proved that the turf was lacking in lasting powers. Circumstances would not then admit of the border being thoroughly overhauled, the top roots were simply freed from this soil, and fresh material added of a lighter character. When the house was closed, the following February a good soaking of tepid water was given. The Vines were watered until the middle of July following when the Grapes were commencing to colour, and water was withheld; only a light sprinkle over the border and pipes twice a day in favourable weather.

In May, about the time the foliage had previously shown the first sign of burning, a thin shading was put over the glass by mixing together some lime and water, adding a little milk, and applying it with the syringe on the outside of the glass. The Vines that year bore an excellent crop of Grapes, the berries swelled to a good size and coloured well; the foliage, by the assistance of the shading and a limited supply of water at the roots, was in a more satisfactory condition, thus proving that Vines growing in strong, retentive soil do not require so much water at the roots as some might imagine. The Grapes so much improved that year, that it was not deemed advisable to remove the whole of the border, but the surface roots were improved by the addition of lighter soil and timely mulchings of stable manure. When any water was required liquid manure was applied in a warm state; added to this, occasional sprinklings on the roof with limewash to lightly shade the foliage from strong sun have now assured a good annual crop of well-finished Grapes. Towards the end of August the shading was allowed to be washed off by rains, and no more was added, so that the wood became thoroughly ripened. In such a case as the one herein described shading is an advantage.

S.

WHY PEACHES FAIL IN THE OPEN.

SOME would have us believe that Peach culture in the open air is a forgotten or unknown art, and that the majority of modern gardeners know nothing of the wonderful skill possessed by our forefathers in perfecting Peaches in the open air, but in my opinion modern gardeners will practise and accomplish everything that will pay and please their employers best, and if Peach culture in the open was as remunerative as it invariably is under glass, good examples of it would be found wherever Peaches were desired; but when all the uncertainty and expense of out-door culture is placed against the excellent results obtainable under glass, I am not surprised that gardeners should adhere to the most certain way of making culture profitable. Our climate here is about the average of what it is in other parts, and some years we have a fine lot of open-air Peaches, while in others we have few or none. I am not inclined to attribute this to inferior culture, but to other causes over which I have little control. As an instance of this, some of our early trees, particularly Hale's Early and Dr. Hogg, on an east wall began to show signs of flowering during the last week in February. To protect them as usual three lots of herring-nets were suspended in front of them, and by the 10th of March they were almost in full bloom. The prospects of a crop then were very bright, but we had 15° of frost on the morning of March 13th, 12° on the following morning, and 7 inches of snow on the 15th. This was accompanied with a bitter cold wind, and the snow was driven everywhere. It found its way through the nets, and as there was no thaw for several days the blooms were hidden under the snow, and when we inspected them on March 19 they were quite brown and withered, and now our prospect of an early Peach crop in the open is destroyed. I cannot tell what practice would have been introduced by the advocates of open-air Peach culture under these circumstances, but I felt very keenly that it was a boon of the greatest value to be able to protect them with glass, and I am not at all surprised that Peach culture under glass should meet with so much favour. As an instance of the advantages of it, I may say that we have an unheated Peach house here. It is very old, and has cost nothing for many years excepting what is necessary to keep the roof in repair. It is a most profitable house, as the trees in it invariably produce a heavy crop, and at the time the open-air trees were being starved, and probably permanently injured, those in the cool house were perfectly snug, and the small fruits are now showing in abundance all over the trees. Here, then, we have the two systems tested fully at a time when the whole season's success of the trees depends on the treatment it is possible to

give them, and the result convinces me more and more of the great uncertainty of the one and the decided advantage of the other. Most of us know how much the success of the fruit crops depends on the state of the weather at the time the trees are in blossom. The early-flowering ones are the most liable to be injured, and then is the time when nothing but a covering of glass will save them. J. MITCH.

Margam.

SPUR-PRUNING PEACHES.

A CORRESPONDENT, "X." (p. 301), inquires if spur-pruning is out of the question when a healthy tree of Early Grosse Mignonne which has been root-pruned refuses to bear a crop. If "X." will explain what he means by spur-pruning, also if his Peaches are growing against a wall or under glass, a satisfactory reply may easily be given. The variety in question is not a difficult tree to fruit, as I have forced it for many years, and consider it the very best of all the early Peaches. It also does well on open walls, but being slightly tender as compared with Royal George and other small-flowered varieties, it should have a good aspect, where the wood can be thoroughly ripened, otherwise many of the flower and wood-buds will perish and drop during the winter. Assuming that the tree, in good health, is growing under glass, it is only reasonable to suppose there is something radically wrong in the detailed management, such, for instance, as an insufficient supply of water to the roots, or too much heat when forcing is commenced. If either of these defects exist, this or any other variety will cast its buds, and spur-pruning whatever that may mean will not ensure a crop of fruit. The spur system is inapplicable to trees on open walls, but shy varieties, notably the beautiful Belle Beauce, a member of the Grosse Mignonne family, when forced early, are often made more fruitful by pinching a few of the side shoots on strong growths instead of rubbing them off. The better to carry out this system, the wood of the preceding year should be laid in extra thin to allow for the full development of the spurs and foliage, then all the strongest growths can be treated as we sometimes treat cordons; but this method has little to recommend it, and unless the cause of sterility—be what it may—is corrected or removed, I am afraid this untidy system will not help "X." out of his difficulty. Has "X." tried extension training—a system peculiarly applicable to all the members of this section, as many of the shoots only carry a minimum of wood-buds; a few at the base and one at the point? Remove the latter and the shoot eventually dies back, as there is nothing left to draw the sap. Lay in all the growths full length, allowing plenty of room for tying in young wood and the full development of the foliage; give plenty of air and water, and this superb Peach will give entire satisfaction in early and mid-season houses, also upon open walls. No early house, in fact, should be considered complete without it, as it starts quickly, ripens early, and the quality of the fruit is exquisite.

W. COLEMAN.

Grapes from South Africa. Many people being interested in the attempts which have been made to send over from South Africa Grapes for the London markets may like to know that I have at the present time in my window a bunch brought over by Mr. W. R. Murray. It has now been in the window for ten days, and is still in first-rate condition, thus showing that with due care in the packing, &c., it will be possible to bring them over in saleable condition. I shall be pleased to show the Grapes to anyone interested in the fruit-producing question.—ARTHUR ROBINSON, 8, Leadenhall Street, E.C.

SHORT NOTE.—FRUIT.

Peach trees losing their leaves.—[H. R. C.] will be glad to know the reason why some branches of the Peach trees on the walls of the vinery have lost all their leaves, and if her gardener is right in waiting to thin the fruit till it staves. As he says it always drops off them, may it not be that the fruit falls from being too crowded?

SEASONABLE WORK AMONG FRUITS.

STRAWBERRIES.

WHERE proper Strawberry houses are provided the successful management of these plants will now depend upon the two elements—air and water—which must be admitted and administered with a liberal hand. A thorough change to bright spring-like weather has already made a wonderful change in forcing houses in general, and Strawberry plants in particular, and the latter being such moisture-loving subjects, the watering-can and the syringe must be kept constantly going, not only to secure full crops of fruit, but also to prevent them from injuring more valuable occupants with which unavoidably they may be brought in contact. Good forced Strawberries are a great acquisition to the dessert, but they are a very expensive luxury, and unless they can be had in plenty it is questionable if in these days of economy it would not be better to give up the risk of introducing spider amongst our Vines and Peaches for the sake of a few ounces of early fruit when later on the same plants would give many pounds worth eating. Light shelves in Peach houses and vineries are tempting to many men who have to make bricks with a very small quantity of straw, but they pay dearly in the end, and for this reason I again repeat the assertion that full crops from light, airy pits through April and May whilst costing least will give most satisfaction. When the fruit in pits and houses is set and thinned, the Pine stove, or what used to be the Pine stove, is generally selected for swelling and ripening, and quickly the berries attain their largest size, but heat and moisture alone are not conducive to flavour; therefore a second, but still a warm house with plenty of ventilation should be provided as a ripening and retarding store. Into this the pots should be transferred as soon as the fruit is fairly coloured; water to the roots should be gradually reduced, sun and air should have full play, and the delicious aroma should be the first indication that the fruit is fit for use. Nin-tenths of the early Strawberries and Grapes are used before they are enjoyable or fit for use, but by adopting the dry, airy shelf system, a few days—a few hours even—make an immense improvement in the quality of the fruit, whilst the move forward favours the introduction of fresh batches from the general store. If plants of the early sorts are intended for autumn fruiting, this passage through the airy house fits them for the cold pits, where, after being dipped in sulphur water, they should remain to harden off before they are planted out.

GENERAL CROPS.

Plants from which general and late crops are expected will now be in every stage from the bursting of the crowns to the setting of the fruit. To secure the greatest weight the plants are capable of giving the soil should be well rammed and top-dressed to ensure the even passage of water through the balls, and if dry and exposed shelves must be occupied, thin sods of turf, Grass side downwards, form an excellent foundation for the pots. Many people use saucers, but of the two I give preference to turf, as the latter, whilst absorbing liquid and throwing up a continuous stream of moisture, is always free from stagnant water. Moreover, when the plants and turf are introduced together and do not part company until after the crop is gathered, these richly charged sods form a fine feeding ground for the crotch roots when the fruit is swelling. Read's patent from this time forward will play a very important part amongst shelf plants not only subject to spider, but also to mildew. The two, fortunately, can be settled with sulphur water, which may be freely used after the sun has left the roof in the afternoon. As these plants come into flower the trusses should be propped or secured with forked sticks to prevent eventual injury to the stalks and fruit, and all weak and superfluous buds should be pinched off before they open.

Latest crops.—As these are to shake hands with the Vicomtesse, La Grosse, and that excellent early Strawberry, Prince of Wales, the plants should be made, or rather kept in presentable condition by carefully plunging in leaves, old tan, if free from

worms or some other moisture-absorbing material. Late sorts should not be disturbed if it can be avoided, as the roots creep through the apertures during the winter and perform good service when the fruit is swelling in May, and watering becomes a heavy operation. To avoid this, I draw every alternate row for succeeding forced plants and leave the others to fruit where they have been plunged during the winter. As the plants give heavy crops of fruit, a plentiful supply of Birch twigs should be stuck into the pots to carry the trusses well above the bed before they rise. Mulching, too, in the form of short manure or leaf-mould may be placed all over the surface, and water in abundance must be given on fine mornings. If likely to get too forward the lights may be thrown off the pits every morning, especially in mild, showery weather, and closed before nightfall. On the other hand, late, unheated pits may be pushed forward by shutting up with sun-heat and moisture when ordinary forcing houses are closed for the day. Being impatient of confined or condensed moisture, cold pits so treated should always have a little air through the night.

VINES.

The fruit in early houses started last November will now be taking the last swelling, and possibly the most forward berries will be colouring. If the roots are likely to require more water before the Grapes are cut, a substantial supply that will carry them through should be given without delay. The ripening period being yet some weeks ahead, clear diluted liquid at a temperature of 80° may be used with advantage, especially where the Vines are aged or carrying heavy crops of fruit. The same liquid may also be used for dampening the floors and filling the evaporating pans until a drier atmosphere becomes necessary. As days increase in length, and bright, sunny weather prevails, a liberal circulation of warm air will be found an important factor in laying on colour and bloom, but great care must be observed in the admission of this element, as depressing checks, although of short duration, are often fatal to perfect finish. If the laterals have been closely pinched, free growth, provided they do not reach the glass and so impede the circulation of air, may now be allowed to develop, as good black Grapes cannot be obtained from Vines that are not well furnished with plenty of healthy leaves and active laterals. The temperature may now range about 65° to 68° at night with air, and 75° to 80° by day, but much as colouring Grapes require and enjoy fresh air, the house must always be closed for a few hours in the afternoon to swell up the berries.

Vines in pots still more forward than the preceding must also have more fresh air with just sufficient fire-heat to keep it moving and also to prevent a sudden decline in the temperature. If the roots have found their way into the plunging material, as may easily be divined by the vigour of the laterals, there will be less danger of flagging, but this aid must not be traded upon by allowing the compost in the pots to become dry, at least for the present, and when the Grapes are ripe just sufficient to keep the foliage fresh and the laterals growing must be given until the crop is removed. Hamburgs in pots do not often suffer under liberal watering quite down to the finish, but that excellent early forcing Grape Madresfield Court Muscat, also Foster's Seedling require a little more care, otherwise they may crack when nearly ripe. Cracking does not, however, often attend pot Vines whose roots are active; still, it is well to be ever on the alert, as I have known a sudden change from a high and dry temperature to converse conditions the most common cause of cracking later in the season.

Midseason houses.—Growth in these is now rapid, and daily attention to stopping, tying, and thinning will keep all hands fully occupied. Tying down may sometimes be deferred with advantage, but stopping should always be performed as soon as the points of the shoots can be caught with the thumb-nail, as checks and waste of force, independently of bleeding from unsightly knife cuts, are then avoided

The thinning of the bunches is another operation which should not be delayed a day longer than is absolutely necessary. It is usual to allow Muscats and other shy setters to carry a few superfluous clusters beyond the flowering stage, but this practice may be carried to excess, as quantity does not secure success unless other conditions are right, and all the bunches come into flower simultaneously. Inside borders will now take copious supplies of tepid water, and a good layer of fresh stable litter should be laid over the external roots to protect them from drought. The rainfall this season has been light, and a covering of this kind, whilst letting in solar heat and air, will prevent them from descending to the drainage. It rarely happens that the outside borders require artificial supplies so early in the season, but unless we have a steady fall of rain by the time the Grapes are set, a good supply through the hose will do no harm.

Late houses.—The Vines in these should be well syringed twice a day until the Grapes come into flower; the borders, too, should be well mulched inside with short manure; outside, as I have just observed, with fresh stable manure well charged with ammonia to be washed in by spring showers. Late Vines which make all their growth during the summer months, and whose roots are carefully protected from October to Christmas, do not, as a rule, receive enough water, especially when the borders lie high and dry upon a foot or more of clean drainage. To counteract the effect of drought these sandwiches are not infrequently soured and soddened by thick coverings of rotten manure which poisons the late and half-ripened roots and fibres, when shanking, or want of colour, or both follow. When this does not happen a plethora of rich animal manure is more conducive to a rank growth of wood and foliage than rich vinous fruit; therefore, notwithstanding the fact that we cannot have Grapes without leaves, rich phosphates, in the form of bone-dust, Thomson's Vine manure, or the like, should be sown on the borders and moderately covered with fresh stable litter, but not to an extent that will exclude sun-heat and fresh air. By this mode of treatment the borders will soon attain our average earth temperature, root action will be early, and when, after the turn of midsummer, the Vines are feeling the weight of their load, a good mulch of manure washed in by copious supplies of water from the hose, if not from the clouds, will sustain lateral growth—the best of all indications that the Grapes will colour properly.

PEACHES.

The fruit in the earliest houses will now be passing through the tantalising stage of stoning, and as well may we try to move the Pyramids as venture on the disastrous attempt to start them on the last swelling before this process is complete. The daily routine of watering, syringing, and airing must be carried on in the usual way, and tying down, if absolutely necessary, may be performed, but unless the shoots are getting up to the glass, I always prefer giving the trees a little freedom until the Peaches begin to swell. When this unmistakable stage sets in, the final thinning, pinching where necessary to the proper balance of the trees, and tying down must be performed. If fine and perfect fruit is wanted, the trees should be under rather than overcropped, and all pendent fruits as far as is practicable should be removed. These, however, where blossom-thinning is practised, will not be numerous, or where they exist and are wanted an effort should be made to turn and support them with their points to the sun. An adept at this work will raise almost every fruit, and by the use of short pieces of lath laid on or tied to the trellis will fix them in their places. A pale Peach by some is considered as good as a dark one, but Peaches in the eye of a good judge are not considered perfect at every point where colour is wanting. If old trees were heavily mulched as soon as the fruit was thinned, copious supplies of warm diluted liquid will complete their bill of fare. Young ones whose behaviour at the outset was doubtful may or they may not require manure. If strong and the crop is light, the liquid will be found sufficient; if carrying full crops, a moderate mulch will do them no harm.

Upon this point the grower must be the best judge; but it must be borne in mind that trees under glass, although they make shoots more than 3 feet in length, can always be ripened to the points, and once properly ripened something must be radically wrong if they do not carry full crops of fruit. If early maturity is important, more heat may now be given to the trees, especially by day, when the temperature may run up to 80° after closing, with plenty of moisture. The chink of fresh air should, however, be admitted at nightfall, and the figures through the hours of darkness should not exceed 60° to 65°.

Succession houses.—The most pressing work in these will be the final disbudding, heeling down, and more thinning. If properly set, a very small surplus will suffice for dropping, as well-managed trees should not cast their fruit after this date. Unless Strawberries have been started in this house spider will not yet be present; indeed, there is no excuse for its appearance at any time; but should it crop up, a small piece of soft soap and a handful of sulphur added to the syringing water will check its course in a very short time. Pure soft water, it is needless to repeat, should always be provided for syringing purposes, as it is not only best for the foliage, but being free from lime or sediment it leaves nothing that is objectionable upon the fruit. Twice a day should now be the rule—the first time soon after night air is shut off, the second when the house is closed for the day. If plied backwards and forwards every leaf will be bathed, and the old wood will be thoroughly moistened. Aphids, too, must be watched. So far this promises to be an aphid season, but timely attention before the leaves become curled is the most economical course to pursue. Cheaper still is the weekly puff with Bloxham's patent fumigator, whether fly is present or absent.

Late houses.—The trees in these are marvels of fertility, and appear to be setting well. We ply the syringe pretty freely in this department throughout the season, allowing the spray to fall lightly during the height of inflorescence, and every flower seems to set well. As these trees are generally planted in external borders, the latter should be repeatedly hosed and well mulched, for once allowed to get dry, insect pests will be more plentiful than the fruit. Having a few healthy pot trees more than twenty years old, some time ago they were transferred to tubs and placed in a glass shed. When these became the worse for wear the sides were taken away and replaced with a 9-inch wall of turf. In summer we bury the balls in long litter and hose the tops and roots with cold water copiously. The heads are about 9 feet through and always carry enormous crops of good fruit, not uniformly high coloured, but equal to the general run of market Peaches. Growers who do not succeed well with pot trees, or cannot devote time to watering twice a day, will do well to try this plan, as the trees crop like Apple trees, and are as easily managed. W. C.

NOTES OF THE WEEK.

Hardiness of Acacia dealbata.—We have received a flowering branch of this from a plant which has been growing outdoors at Kingswear, Dartmouth, for the past five years. It blooms freely every season, and is a grand object when in full flower.

Chionodoxa Luciliae.—I send you a spike of this bearing nineteen flowers. The flowers individually are not so large and beautiful as when fewer in number.—L.
* A very fine spike of this favourite spring-flowering bulb.—Ed.

Salvia Heeri.—This is probably one of the very best for winter flowering. We recently saw it in good condition at Plawhatch, Sussex. The flowers are borne in great profusion, and their bright scarlet colour is highly effective at a dull time of the year.—A. HERRINGTON.

Narcissi Horsfieldi and Sir Watkin.—I send you blooms of Horsfieldi and Sir Watkin, also var. Leedsi. Horsfieldi has been in bloom about a fortnight here. Bishop Mann set standards inches high as white Daffodil, and is nearly out of bloom now, and I cannot send any more blooms to next conference.—W. B. H., *Cork*.

* A beautiful gathering; Horsfieldi, very large; Leedsi, very chaste and pretty.—Ed.

Daffodil committee.—Members and growers of white Daffodil will very much oblige by bringing out blooms of Narcissus tortuosus to the next meeting of the Daffodil committee on April 12. The blooms must be from the guaranteed

* stock as known by that name prior to the 1884 conference, and in their possession for three years.—A MEMBER OF THE DAFFODIL COMMITTEE.

Japanese Camellias.—We have received from Mr. W. Gordon, Twickenham, several varieties of Japanese Camellias. They are all semi-double. Worthy of note were the following: Lady Jane, bright red, the petals of good substance; Lady Vansittart, the flowers profusely splashed with red on a white ground; Lady Clara, pinkish shaded; and Lady Vere de Vere, white, splashed with red.

Primula cashmeriana.—I send you blossoms of seedling *Primula cashmeriana*, gathered out of doors the last day of March, to show how effective they are in early spring-time. The plants commenced to bloom four weeks ago, passed unharmed through all the sharp frosts and snow showers of that month, and are now a soft mass of lilac, each plant bearing from six to ten flower-heads. The young plants were pricked out in their present quarters, a cool, somewhat shaded border, last summer.—L. ST. BRIDGD.

* * Large and handsome spikes of flower. We have scarcely ever seen this variety bearing so large trusses.—Ed.

Hardy Polyantheses.—I forward you blooms of two hardy Primroses, viz., Faust and Sovereign. They are taken, of course, from plants grown under glass. The former has hose-in-hose flowers of a very rich crimson shade, which show up well in the sunshine; the latter is a fine yellow variety. I also enclose blooms of Polyanthus William the Fourth, an old red ground, gold-laced variety. These were gathered from plants grown in the open ground all last summer.—A. D.

* * A very fine gathering. That named Faust is very striking, the colour of a deep crimson, with a bright yellow eye. Sovereign, clear yellow, also is very pretty. The Polyantheses were good, the gold lacing being very even and distinct.—Ed.

Arctotis undulata is one of the less common plants among the crowds of showy flowers that now adorn the greenhouse at Kew. Its uncommon look attracts the attention of those who take an interest in the plant. It has flowers the shape of those of a pot Marigold, but much larger and of a glowing bright orange colour. They are borne singly on tall stalks rising above the foliage, which is deeply lobed and silvery beneath. It is a half-hardy plant, and really only suitable for pot culture in a greenhouse; in some places it may be grown outdoors as well as other species of *Arctotis*.—W. G.

Spring flowers at Weybridge.—The late trying winter seems to have made the early spring flowers late, but more beautiful even than usual. At Oakwood we have a bank of loam covered with brown and green Moss; through this small plants of *Hepaticas* have thrown up their flowers; I counted eight shades of pink and as many of blue; these, with two sorts of white, give an effect which could hardly be beaten in Switzerland. In some bays of the rockwork *Chionodoxa Luciliae*, *Scilla sibirica*, a *Galanthus* called *Redoutei*, but as I am told incorrectly, *Narcissus nanus*, and *Helleborus purpurascens* side by side look very pretty. *Chionodoxa sardensis*, when in good chumps, and *Scilla taurica* are, I think, equal in beauty to the favourite *Glory of the Snow* (*Chionodoxa Luciliae*); *Anemone fulgens* is very late, and will not bloom for some days; *Narcissus minimus*, which I owe to the kindness of its collector, is much admired.—GEORGE F. WILSON.

The Neapolitan Allium is a bulb not half enough grown as a pot plant for the greenhouse or conservatory in early spring. All who see the glorious masses of the white *Allium*, which for the past few weeks have been in perfection in the greenhouse (No. 4) at Kew, are charmed with it, and very few visitors know it. We have never seen it better grown than it is at Kew this year, for the slender flower-stems are in some cases over 2 feet high, and have broad heads of pure white flowers which are quite devoid of any Garlic odour. The bulbs have, of course, been forced into bloom, and this needs to be carefully carried out, for if too hurriedly done the result will be a paucity of flowers. One of the most beautiful groups of plants to be seen in this house now is composed of this white *Allium*, the glittering scarlet *Anemone fulgens*, also forced pot plants, and a pale yellow *Hyacinth*—a charming harmony of colour.—W. G.

FLOWER GARDEN.

LENTEN ROSES.

THE real value of this class of Hellebores for decoration at this early season of the year can hardly be over-estimated, and seeing how distinct they are from all other plants used for that purpose just now, the wonder is that they are not more largely represented in some of their many forms at least in every garden. This will be more apparent when we remember that they also have come under the magic influence of the improver or hybridiser; the variety of form and colour already in cultivation is indeed most striking, the large majority of them being highly ornamental. Their value as commercial plants will, of course, be regulated by the supply and demand, but there can be little doubt that if they are brought forward at the right time, they will be as fully appreciated as their merits warrant them to be. Not having had experience, we are unable to say whether they will stand forcing, but we have gathered them early enough for market purposes, simply grown under the protection of a cold frame, dispensing even in severe weather with all artificial covering whatever.

Unlike *H. niger* and its varieties, about which it is needless to speak, so well are they known and appreciated in gardens, the Lenten Roses seem to try the patience of the cultivator to a very large extent, especially in the neighbourhood of London. Out of doors and under similar conditions to *H. niger*, they are very difficult to manage without some means of protection; the prevalent east winds, combined with an impure atmosphere, render their success very doubtful, unless indeed under specially favourable circumstances. At this early season the young growths are most active, and of course very susceptible to injury; the fresh tender leaves and the unopened flowers are often blasted and rendered useless for decoration if exposed to the bitter winds for a single night. In choosing a site for these Hellebores, one completely sheltered from the north and east should be selected, and even then it may be found necessary to use portable lights for their better protection. We have never yet seen their cultivation attempted in the conservatory, where doubtless they would yield a good return, provided a light situation, and one not too far from the glass could be given them; they could be planted out in the borders as an edging, or mixed with other flowers, such as Hyacinths, Snowdrops, &c., with good effect, and without any fear of their suffering. The following are a few of the best distinct types:—

H. ABSCHASICUS.—This plant we believe to be the same as *H. atropurpureus* of the *Botanical Magazine*; it has a fine robust growth, forming neat clumps and numerous rose-purple flowers, prettily shown up by the pure white stamens; unfortunately, it is amongst the first to suffer by the winds, which turn the buds black, their entire destruction only being a matter of time.

H. ANTIQUORUM is one of the most floriferous, not even excepting orientalis. The blooms are produced in great quantity, pale purple with beautifully imbricating sepals; the leaves are also handsome, forming dense tufts of bright green all through the summer months.

H. COLCHICUS is one of the best as regards colour; the flowers are deep plum-purple, covered over with a glaucous hue, enhancing their beauty wonderfully. The young leaves are purple when opening, losing little indeed until they are full grown. The varieties *coccineus* and *punctatus* are really charming, and amongst the best in cultivation. They stand well in the open, with slight protection at night.

H. GUTTATUS with its spotted flowers is very ornamental. It is a free bloomer, comparatively robust, producing large, well-formed, white flowers, with scattered purple spots about half-way up the sepals. This species has had much to do with very many of the hybrids cultivated in gardens; it

crosses freely with *abschasicus*, *colchicus*, and others, the presence of the spots indicating its parentage.

H. OLYMPICUS is a rather weakly-growing kind, with greenish white flowers. Professor Schleicher is a good variety.

H. ORIENTALIS, next to *antiquorum*, is the freest of this section. It produces flowers in great abundance, pure white, large, and well formed. It stands the cold better than most of the others, forming fine, fresh green tufts of leaves.

H. PURPURASCENS, deep purple, dwarf, and very ornamental. Other species or hybrid varieties worthy of notice are *Apotheker Bogren*, rich purple-rose; *Inspector Hartwig*, plum-purple; *Gretchen Heinemann*, rosy purple; *Mrs. Irene Heinemann*, pale purple, spotted carmine; *Councillor Benary*, snow-white, with large purple spots; *Willy Schmidt*, pure white, one of the best. Others are *torquatus*, *luridus*, *dumetorum*, *graveolens*, *Bocconi*, &c., all nearly related to *H. viridis*. K.

THE MOUNT PARNASSUS SCABIOUS.

(PTEROCEPHALUS PARNASSI.)

THIS very neat little plant is valuable for rock and alpine gardening in warm soils in our southern counties, but in other parts its hardiness would be doubtful. Where it does well it is one of the best of plants for covering spaces

The Mount Parnassus Scabious (*Pteroccephalus parnassi*).
Engraved for THE GARDEN from a photograph.

where it is desirable to have a low, close-growing and pretty carpet. It likes a free, open place in full sunlight and a light soil, and grows fast under these conditions. The leaves are a light grey-green and the flowers flesh-coloured.

Soldanella alpina.—This plant, as it may be seen at present in full flower on the rockery at Kew, is an interesting as well as a beautiful hardy alpine. The flowers can hardly be said to be brilliant, but they are produced in such quantities on small plants that it is well worth a place in the rock garden. The flowers droop like a Snowdrop, of a bluish colour, open bell-shaped, and prettily fringed at the mouth with narrow bands of the same tint. In mild localities and in sheltered spots, where water can be given or withheld at pleasure, this plant will do well and flower profusely, and even in exposed localities, where it can be protected from the late spring frosts, it will thrive. A mixture of peat, sand, and a little loam suits it admirably. Almost the same treatment will do for *S. pusilla*, *minima*, *montana*, and their forms, among which the white ones are really handsome, and well worth being cared for in pots.—K.

Hypericum olympicum.—In the article on the above St John's-wort in THE GARDEN, April 2 (p. 302), it is stated to be "perfectly hardy and indifferent as to soil." The same statement as to hardiness is, I see, made in the catalogues of some of the nurserymen. We must, all of us, of course, speak for ourselves, but I can only say that in my own garden, in the favoured county of Kent, considerably south of London, I have entirely failed to keep this plant,

either in common soil or in specially prepared soil, or well-drained and warm situations on the rockery. I have lost it from cold rains and frost. This I much regret, for it is in my opinion the most beautiful of the family, the glaucous foliage giving a softness and richness to the plant which are lacking in other species with which I am acquainted.—J. C. L.

THE FORTUNATE ISLES.

AT this season the delightfully green slopes of the steep hills on the northern side of Santa Cruz Bay, the chief port of the island of Teneriffe, do not belie their promise of flowers on closer acquaintance; indeed, it is hard to imagine anything more interesting to a flower-loving and somewhat botanic student than the flora of these seaside cliffs.

The first thing that claims attention, even while still at sea, is the curious growth of what proves on examination to be the well-known *Euphorbia canariensis*. This *Euphorbia* is so like a Cactus, that it deserves description, being leafless, upright, and closely branching, with four-angled, thick, and fleshy stems, which show short spines at each angle, and of a pale green colour. It is at first hardly possible to believe it aught but a Cactus, but in summer when the small and green Spurge-flower is to be seen, it is, of course, easily identified. Now, the only test is to wound with a knife one of the fleshy

branches, when the white, milky, and viscid juice that oozes out proves its relation to the genus *Euphorbia*. This juice is very acrid, and blisters the skin if allowed to touch it, as one of our party found out to his cost. Sometimes this bush grows to a large and almost tree-like size, but here its upright stems do not rise above 5 feet or 6 feet, and its abundant growth produces a very weird and desert-like effect. Just now, however, the ground is bright with flowers and flowering shrubs that recall summer gardens in England. The Marguerite or Paris Daisy bush (*Pyrethrum fruticosum*) is native here, and grows and flowers most abundantly, being dwarfer and more floriferous than under cultivation. Growing with it, and also in full flower, bushes of Lavender (*L. abrotanoides*) make a pretty contrast by their lavender-coloured and branched spikes of bloom, rising on tall stems from the low-growing and finely-divided foliage. Orange Calendulas of large size are very cheerful on the bare spaces; and nestling among the rocks is a pretty Scilla, with lilac buds and small, whitish flowers in long scapes. A Myrtle-leaved Thyme grows here so exactly like the small-leaved Myrtle in habit and scent, that had I not spied one small twig with a few lilac Thyme blossoms open, I should never have suspected such a mistake. Perhaps the greatest surprise was to find quantities of a small white single Dahlia, apparently identical with our garden plant, save for its diminutive size; how this should be naturalised all over the island in dry and rocky places, and when introduced, would be most interesting to ascertain. Then a wild and sub-shrubby *Celosia*, with woody root-stock and long, thin spikes of pinkish flowers, recalls the brilliant heads of the cultivated Cockcomb, though far inferior to them from a gardening point of view; and here is a curious little Composite, also apparently of American type, with grey-green leaves and yellow-rayed flowers smothered in long, leafy bracts. Behind a big rock, a Hemlock, with pale green leaves divided to Fern-like tenuity, is the only representative of the Umbellifers on this eastern coast; but on the western shores *Sampere* grows freely in company with *Mesembryanthemum crystallinum* (our familiar Ice plant) and a dainty *Arenaria* with shrubby

growth and pinky white blossoms. Perhaps the two most beautiful flowers on the rocks near the sea are the bright pink form of *Statice spathulata* and the grand lilac panicles of the Tenerife *Statice canariensis*, whose neater form, *Statice profusa*, is so much grown in our warm greenhouses. *Echinus*, though not in flower, promise a great variety of beauty, rivalling the stately Madeira form, *Echinus fastuosus*, whose sky-blue panicles and shrubby growth will not stand our northern climate or lend themselves to pot culture.

Leaving the seashore and climbing some two thousand feet up, the Tenerife form of *Cineraria vulgaris* is abundant by the roadside. Here it is almost always red-lilac in colour, with three or at the most four large, but thin-rayed flowers in a head, and with a decidedly pleasant smell, quite distinct from the Canarian form, which is so like that grown in gardens, with large heads of flower with shorter petals and a rather coarse smell like Ragwort. Pale yellow single *Oxalis* and orange *Nasturtium* have naturalised themselves everywhere, and with the *Cinerarias* make every bank gay—a happy feeding-ground for swarms of Red Admiral and Painted Lady butterflies.

One charming feature is the way in which the Hare's-foot Fern (*Davallia canariensis*), *Sedum tubiforme* or a form very closely akin, and a handsome *Sonchus* (*S. squarrosus*), cover the file-topped walls in every village, and grow boldly on the barest possible surfaces in a remarkable way. *Sonchus squarrosus* is so handsome, with its slender flower-stem crowned with a large flat head of clear yellow flowers rising out of a green rosette of leaves, that it is well worthy of cultivation on wall-tops in warm situations, if perchance it be sufficiently hardy. Violets are still sweet in shady and damp ravines, and send up whiffs of scent which mingle gratefully with that of another garden favourite, the well-known *Genista*, or *Cytisus*, which we grow in pots in England. *Genista canariensis* is here growing wild on the cliffs, and as full of flower as possible—a most welcome friend to greet a gardener in a strange land.

But this is the land of Brooms, indeed, and it would be difficult to find a season of the year when no Broom was in flower, so another is soon added to the list. *Genista prolifica*, a Broom from the beautiful isle of Palma, has been introduced here, and is grown largely both as a fence and also as a forage plant. This is now flowering freely, and has quite the effect of a Hawthorn bush in the month of May, for its creamy white blossoms, clustering amid the large bright green leaves, are quite unlike any other shrubby Broom. Although it grows to a height of 10 feet, it seems also to bear cropping or mowing down, and in the hot and dry summer the natives find it more useful than even Lucerne, which dries up more readily. *Genista monosperma*, the white Broom grown in gardens, and the beautiful weeping *Genista filipes*, the pride of Palma, which is all but lost to cultivation, are now and then to be seen, but the latter seeds so rarely that its propagation is difficult. *Genista hispanica*, our Spanish Broom, with its golden spikes of bloom, is, of course, here abundantly wild and more or less in flower. By the roadside it attains a very considerable height, with a trunk 5 inches in diameter. The wood is very hard and useful as fuel.

Yet two more Brooms are peculiar to this island, and seem to refuse to grow elsewhere; both grow high up on the great Peak of Tenerife, where for a zone of 3000 feet they almost

monopolise vegetation. As they do not flower till late in spring at such an elevation, I did not see their blossoms, but their growth, which I was able to see, deserves remark. *Cytisus*, or *Genista*, *nubigenus*, the *Retoma* of the natives, in habit resembles the Spanish Broom, but grows still larger, forming bushes 15 feet in height and at least as much through. Its woody trunks and stems are valued as fuel, and when its small creamy white flowers cluster over the naked twigs of the previous year's growth it is said to be beautiful, while the honey is so abundant, that hundreds of hives of bees are sent up there just as we at home send the hives to the moors in August. The peculiar grey-green of the bare twigs rising out of the snow when I was there was so unusual, that it would be prized for its winter effect could we grow it in English gardens.

The second Broom peculiar to this peak is called by the natives *Codeso*, and is in botanical works now called *Adenocarpus frankenioides*. It is quite distinct from the last. It forms low, close bushes quite like stunted Gorse, but without any prickles. It is evergreen, or "ever brown," with tiny trefoil leaves clustering like Moss on the stems, and its orange flowers, large in proportion, are much admired by natives in summer. Another *Adenocarpus*, *A. viscosus*, is also found in the islands, while *A. decorticans* seems confined to Spain.

The wealth of beautiful shrubs and trees peculiar to these volcanic islands is most remarkable when to these is added the Canary Pine, which still remains here and there in pristine beauty, with rich brown-red bark and long pale green needles, and flat, Cedar-like side branches. Various Hollies and Laurels, not widely differing from known types, grow in the ravines, but on the dry slopes a most beautiful *Cistus* with shining evergreen leaves and aromatic scent is found, and as its blossoms are large and bright rose in colour, it is a most desirable plant for English rock gardens, if seed has been imported. I believe it is now to be placed in a genus apart and called *Rhodocistus canariensis*. *Cistus monspeliensis* is said to grow here, but I did not observe it. *Asphodelus ramosus* seems ubiquitous, and grows everywhere, just as it does in Italy, but other bulbous plants are few, save *Arum Draunculus*, which, in company with *Davallia canariensis*, clothes acres of volcanic boulders that are piled up on every side.

Before leaving the wilds and descending to the gardens and Dragon trees of Orotava, so famous in bygone days, there is one more native plant so beautiful and so rare, that had it not been preserved and propagated in one garden, it might have been lost to us for ever: this is the beautiful *Pico di Palma* of the native, or *Lotus Pylorhynchus*, which grows in one solitary ravine on the southern slopes of Tenerife.

A deep scarlet, trailing Pea, perennial, with slender grey-green leaves, and showing masses of flowers large in proportion, hanging in festoons 3 feet and 4 feet down the terraced walls of a garden facing north, is a treasure that will, I hope, be pictured ere very long in the pages of THE GARDEN. It is represented as being nearly or quite hardy, and will in any case be of the greatest value in a garden, where it will be useful as a dwarf edging to summer beds, or the glory of a sunny rockwork, if our atmosphere allows its crimson and silver sheen to retain its brilliancy. Still, until carefully tried, it is hard to say how it will succeed, though the fact of its flowering on a northern aspect in

winter at Orotava is in its favour; but when Coffee trees, Oranges, and Bananas are growing in the same garden, it is difficult to believe that it can thrive really well in England. The quaint old Dragon trees round which the villages have clustered; the treasures of the botanic garden to which Mr. Wildprecht has devoted so much care; the roadway sides with *Wigandias*, blue with blossom, or *Ferdinandias*, gay with corymbs of orange and white Daisy heads, or *Oleanders* already opening their first rosy flowers; above all, the almost virgin islands of Palma and Gomera, which another year will be accessible to travellers, each and all deserve so much admiration, that I can but say, "go and see;" do not trust merely to the hurried description of a lover of sunshine. E. H. WOODALL.

ANNUAL DOUBLE MARGUERITES.

I AM, of course, alluding to the *C. coronarium* section, and I often wonder these are not more grown for cutting purposes, for they are easily cultivated, very free, and also continuous in bloom. When the Sicilian *C. coronarium* first began to develop the double forms is probably not recorded, but they were known in English gardens three-quarters of a century ago. It is a remarkable fact that it would be difficult to find the single form of *C. coronarium* in any seed list, and it would seem as if it had quite gone out of cultivation. Some three or four years ago I had sent to me some seeds of an African Daisy so-called, and it turned out to be the very subject.

The double forms of *C. coronarium* are white and yellow, and they have flat petals, recurring like those of a Victoria Aster, and there is also a variety of each in which the petals are quilled. Being fertile, they can be readily raised from seed, but they are found to vary—some are semi-double, others are fully double, and the best thing to do is to make a good selection from the latter and then propagate it by means of cuttings, which strike readily enough. Cutting plants are found to be dwarfer and more floriferous than those raised from seed, and therefore better adapted for pot culture. Of the varieties that have been selected and distributed by means of cuttings there are *Aurora*, bright yellow, the flowers small, and wonderfully neat and pretty; and *The Bride*, a white counterpart of this, and equally valuable in all respects. The best double yellow is *Yellow Perfection*, a larger flower than *Aurora*, fuller, and even more symmetrical. A new Continental variety has appeared named *conchiflorum flore-pleno*, which bears white flowers and broad shell-like petals, and is said to be remarkably free-flowering.

Though originally classed with the half hardy annuals, *C. coronarium* and its varieties are really hardy annuals, and grow freely when seeds are sown in the open ground. The soil should be fairly light and rich if good bold branching plants and fine flowers are desired. The seeds should be sown thinly and the plants thinned out as they increase in size, that they may have ample space in which to develop. Those who have to furnish quantities of cut flowers during the season will find these annual *Chrysanthemums* invaluable for cutting from, and should grow them in quantity. R. D.

SHORT NOTES.—FLOWER.

Sea sand for plants.—We have, about 14 miles from this place, a sea sand depot, which is let at £100 a year, and in this way we have a good opportunity of testing the value of this article; we use it largely for all purposes where sand is required, and find it excellent for all kinds of plants. Cuttings root freely in it, large plants are much benefited by it, and Carrots and other crops in the kitchen garden do exceedingly well in it. I prefer it to any other kind of sand. —J. MUR, *Margem*.

Wachendorfia thyrsoiflora and Orthrosanthus multiflorus.—Your correspondent "K." has done well in calling attention to and recommending the former of these beautiful plants in THE GARDEN (p. 295), April 2, and he would confer a further benefit on some of us if he can tell us where it is to be procured. Can he or anyone else also tell us whether *Orthrosanthus multiflorus* is also procurable? I saw these two plants growing side by side in a damp place on the Kew rockery some years ago, and was struck by both

of them. Both are apparently hardy, though the latter comes from N. Holland. I have never seen either of these plants offered in any tradesman's catalogue.—J. C. L.

SOME USEFUL CLIMBERS AND SUITABLE PLANTS FOR WALLS.

As all of the following plants are cultivated in pots in nurseries, they can be planted at any time of the year, but this is the best season in which to do it. Such plants grown in pots are generally what is termed well established, and the roots have coiled themselves round the balls of soil. When, therefore, a plant rooted in this way is turned out of the pot, the outer roots should be carefully unwound, at the same time taking care not to loosen too much of the soil forming the centre of the ball. The outer roots should be carefully spread in the hole dug for their reception. To dig a small hole, and put into it a ball of roots, such as that just described, without unwinding any, is useless. The place in which to plant should be of sufficient dimensions to admit of the roots being spread out as above directed. More than that. Climbers are generally gross feeders, and especially is this true of the varieties of Clematis. In all cases where permanent planting is done, the soil should be dug out to the depth of 2 feet, and a good dressing of well decomposed manure applied, mixing in some good soil with it until enough has been put in to enable the plant to be placed in position, not burying it too deep, so that mulching can be added. The soil also should be trodden firmly about the roots, and, of course, every planter who knows his work will make due allowances for the inevitable sinking of the soil.

The most suitable plants are Virginian Creepers—*Ampelopsis hederacea*, the old North American Virginian Creeper, and its congener from Japan, the elegant *A. Veitchi*. This last clings to the wall or whatever it grows against, and therefore saves a lot of trouble in the matter of nailing. Then comes *Aristolochia Sipho*, a tall, twining plant of rapid growth, with large heart-shaped leaves and flowers of curious form, bent like a syphon, brownish yellow in colour and sweet-scented, but not abundantly produced. *Berberidopsis corallina* is an evergreen shrub of a rather scandent habit; the coral-red flowers are abundantly produced in terminal pendulous racemes on long red peduncles. But it should have some protection during frost, as when it blooms it makes a gorgeous sight. *Berberis dulcis* is a very pretty, early-flowering shrub, quite hardy against a wall, and worthy of being grown in every garden. The flowers are of a deep yellow colour, and followed by edible, globular black berries. *B. stenophylla* is also a most ornamental shrub, profusely laden in April and May with brilliant blossoms, and subsequently with berries; the colour of the flowers is a bright citron yellow. *Bridgesia spicata* is a fast-growing evergreen climbing plant; the blossoms are abundant, but not showy. It is one of the few climbers that are evergreen, and it quickly covers a wall. Who would not plant the fragrant *Chimonanthus fragrans* against a wall? This is all the protection it requires. As a modern writer remarks: "Midst frost and snow, bunches of deliciously fragrant flowers can be gathered each Christmas Day from this winter-loving bush."

Ceanothus azureus and *C. dentatus* are two delightful blue flowering shrubs that bloom abundantly when well established. Of Clematises there are many varieties, spring and summer-flowering, double and single. It is scarcely necessary to give varieties, but this fact should be borne in mind, that the spring-blooming or patens section must not be cut back, because they flower on the ripened wood of the previous year. The vigorous-growing summer-flowering varieties will admit of being cut back close to the ground, much depending, of course, upon the space the plants are required to cover. *Crataegus Pyracantha* is so well known that it simply needs to be described as trailing or climbing against a wall, and as bearing an abundance of red berries through the winter in

large clusters. *Cydonia*, or *Pyrus japonica* makes an excellent wall plant, doing much better in this way than when grown as a bush. Trained against a wall it will grow to the height of 12 feet or 15 feet, and form a really beautiful object. The flowers are bright red, abundantly produced, and expand early. There is a pure white variety also, and one known as *grandiflora* varicolor, that has very large pink and white blossoms. *Wistaria*, or *Glycine sinensis* is a vigorous and rapid-growing climbing plant, and a magnificent ornament to our walls and trellises. It should be planted where there is a good space of wall or fence to cover. Ivies, and especially the common Irish, make excellent wall plants. *Argentea*, silver-blotched; *aurea*, golden-leaved; *palmata*, deeply lobed; *maculata*, mottled; and *tricolor*, various colours, are the best. *Humulus lupulus*, the common Hop, can be used in suitable places with excellent effect. *Jasminum nudiflorum* is one of the most showy of winter-blooming plants, expanding its bright yellow flowers all along its leafless branches from December to February, even midst frost and snow. The common white Cape Jessamine (*J. officinale*) is also a charming subject; and the evergreen *J. revolutum*, a plant that succeeds best against a wall, and produces bright yellow and deliciously fragrant flowers. *Solanum jasminoides* is a pretty climbing plant bearing clusters of white flowers, but it requires a south wall and a sheltered situation, being rather tender. Then there is *Tecoma radicans*, a Virginian climbing shrub, with scarlet and orange trumpet-shaped flowers, which fixes itself to trees or walls by rootlets from the branches, like the Ivy; it is of rapid growth, and soon covers a large space of wall. It is hardy in the south-west and up to the midlands of England. I find I have omitted *Lardizabala biternata*, an evergreen climbing shrub from Chili; the flowers are dark brown, produced in pendulous racemes, expanding in winter. It is a beautiful climber, well worthy of a wall on which to train it, and deserves to be better known. R. D.

Corbularias. The distance between what we have been in the habit of considering typical *C. citrina* and typical *C. nivalis* is wide enough for all practical purposes to warrant the separate names, but from what we have already seen of the variation of the former in the direction of the latter it does not appear difficult to fill all the links in the chain between the two so-called species. Indeed, I should not be surprised that among the recent importations sufficient material to accomplish this will be found before the season is over. Typical *C. nivalis* with us is always dwarf, scarcely rising its pretty flowers above the dwarf, sturdy foliage, the corona orange with slightly deeper-tinted sepals or spurs. In *C. citrina* the corona is as large again, citron-coloured, and no difference between that and the spurs. One variety in the direction of *nivalis* has deeper tinted spurs; and in the other, which I should say is almost intermediate between the two, the flowers are small, two-coloured, as in *nivalis*, about the same tints, the scape being half as long again; the leaves are long and flat, being entirely those of typical *C. citrina*; the habit being altogether more robust than that of *C. nivalis*. The latter is just opening its flowers on the rockery, and we are looking forward to a real spring treat.—K.

White Trumpet Daffodils.—As the season has again come round when we can make progress with the arrangement and classification of our white Daffodils, I should like to ask all growers of them, and especially Irish growers, who have old gardens in which they are established, and who may not previously have paid any very special attention to them, to notice the blooms very carefully, and note down any particulars in which they appear to them to differ from the ordinary common. We have talked a good deal about a trial of white Daffodils, which no doubt will be a very excellent thing when we are ready for it, and have collected all possible materials to ensure its being as successful and as complete as possible. "Eile mit weile" is

a safe rule, and one which in this case we must follow if we do not wish to be compelled to undo each year the work of the preceding. I specially wish gardeners to notice their white Trumpet Daffodils because several beautiful forms which appear to have become extinct in, or may never have existed in English gardens have been found established in old Irish gardens, and I believe that there are still forms which have not yet come into the possession of those who have made a speciality of this section. But although I make the request specially to Irish growers, I by no means limit it to them; I have had several good forms of white sent to me from gardens in different English counties, and I have no doubt but that they are to be found in old English gardens as well as in Irish ones. If the owners of any forms which appear to them to be distinct would be kind enough to forward blooms of them to the Narcissus committee, which meets on April 12, 26, and May 10, they will confer a favour on all who are specially interested in these very beautiful flowers; or if they prefer to send blooms to me, I shall be glad to receive them, and will let the sender know whether they are forms which we already have, or not, and whether they are worth sending on to the committee. Differences might be looked for in the following particulars: Flowers either unusually large or small; trumpets very wide or very narrow; perianth longer than the trumpet or much shorter; perianth divisions very broad or very narrow. H. M. WHITE, *Charleville, Roscrea*.

Spring flowers.—Amongst spring flowers suitable for planting in the semi-neglected or wild garden, none equal, and few are more suitable, than the Glory of the Snow. Where the Grass is not over-rank it does exceedingly well, every year becoming more robust, and sending up stronger flower-stems covered with its charming blue white-eyed blooms. Some Scillas, such as *S. campanulata*, also do well planted in this way. *S. sibirica* and *S. bifolia* are so dwarf that they can only be planted in thin, almost bare spots, where, however, they seem to thrive very well. *Triteleia laxa* and *uniflora* do not seem to be amenable to this treatment, although on sheltered borders in the open they hardly ever fail to produce abundance of flowers. When planted among coarse Grass they begin to dwindle the second year, and in a few seasons disappear altogether. Among Snowdrops, *G. nivalis* seems to be by far the most suitable, and even under trees it yields abundance of its single and double flowers. *G. Elwesii* can hardly be said to be suitable for naturalising, and although apparently more robust than the older sorts, it loses ground when planted in the wild garden.—K.

Eryngium Oliverianum.—In your last week's issue there seem to be some confusion about the plant so beautifully figured on p. 298. It is called *E. amethystinum* Oliverianum, and as these names represent two distinct plants, it may prove misleading to growers who possess either of them. The plant figured is no doubt *E. Oliverianum*, which may be found in nurseries under *E. amethystinum*, and this fact may account for the above. The latter, however, is a dwarf plant, rarely exceeding 18 in. in height, with deeply pinnatifid radical leaves, spiny; the stems are smooth, corymbosely branched, and the involucre leaves, never exceeding seven or eight, lance-shaped with a few teeth at their base, and much longer than the flower-heads; flower-heads, stems, and upper leaves beautiful amethyst-blue. *E. Oliverianum* is more nearly related to *E. alpinum*, and differs from *E. amethystinum* in its being 3 feet or 4 feet high; the lower leaves on long stalks, roundish, and having cordate bases; the stem-leaves are three-lobed; the involucre leaves vary from ten to twelve, lanceolate, bearing five or six teeth on each side. It is readily distinguished by its more robust habit and larger and more numerous steel-blue heads of flowers.—K.

Composition of sand.—I recently read in one of your papers an opinion that sea sand was as good as silver sand for gardening purposes. There are differences of opinion about this matter, and I should like to suggest a reason which does not appear to have gained attention. Our cliffs in this

neighbourhood are composed largely of calcareous sandstone, and if hydrochloric acid be added to a little of our sea sand, there is abundance of effervescence, as it consists largely of carbonate of lime. Now, if the same test be applied to silver sand, there is no effervescence, as it contains no lime. Will not this fact show that the composition of sand, apart from its grit, should be taken into consideration, and will give rise to different results? Having given my theory, I should like the opinion of practical men as bearing on it. — JOHN WHITEFIELD, F.C.S., Scarborough.

ORNAMENTAL GRASSES.

PROPERLY arranged and rightly treated, these Grasses are both pretty and useful. They are pretty when growing, and very useful during the winter in a dried state. The mixed flower borders are the best positions for them, and here the seed may be sown at once thinly in small patches and covered with a little fine soil. Most of the seed germinates quickly, and the seedlings also transplant readily if need be. In some instances, especially where many bulbous-rooted plants are grown, the plan of raising the Grasses in pots or boxes may be preferred. If the seed is sown in little drills, patches of plants can be more readily obtained than by sowing broadcast. On no account should any strong heat be employed in raising the plants, a cold frame being a more suitable position, and the transplanting to the borders ought not to be delayed till they have been starved into premature flowering. Rich land naturally induces the production of stronger flower stems, but ordinary garden soil is quite good enough for such accommodating weed-like subjects.

Gymnopleura latifolia and *Urtica latifolia* grow to a height of about 3 feet, and these, therefore, may go at, or near to, the back of the border. *Diplacne fascicularis*, *Eragrostis cylindrorhiza*, and *Paspalum elegans* usually attain a height of 2 feet, while *Stipa pennata*, *Hordeum jubatum*, *Pennisetum longistylum*, *Bromus macrostachya*, *Briza maxima*, *Chloris truncata*, *Coix lachrymana*, *Grangea maderaspatana*, *Panicum colomum*, *Agrostis argentea*, *Agrostis laxiflora*, and *Agrostis nebulosa* grow from 1 foot to 2 feet in height. For the second row from the front such kinds as *Agrostis dulcis*, *Briza geniculata*, *Briza gracilis*, *Bromus briziformis*, *Chloris radiata*, *Eleusine coracana*, *Eragrostis elegans*, *Eragrostis senegalensis*, *Lagurus ovatus*, *Pennisetum fimbriatum*, and *Tricholena rosea* are suitable. The dwarfest in habit, and the best therefore for the front rows, are *Brizopyrum siculum*, *Chloris elegans*, *Chrysanthus aureus*, *Festuca pectinella*, *Festuca viridis*, *Lasiagrostis argentea*, *Lasiagrostis splendens*, and *Tripsacum dactyloides*.

As a rule these Grasses, or the majority of them, are most appreciated in a dried state, and are extensively grown for house decoration during the winter months. With a very little ingenuity and the display of a moderate amount of taste, handsome bouquets suitable for large vases can be made, while for small vases a bunch of a single variety is usually preferable to mixtures. It must not be supposed that those bright mixtures sold by florists can be obtained by sowing an imported collection of varieties as retailed by all seedsmen, but people with good taste usually prefer the Grasses as grown to those unattractively stained importations. A little judgment is required in the matter of cutting and drying the Grasses. If cut before they are properly matured they keep badly, and are not sufficiently stiff after drying. On the other hand, if left till they are fully ripe much of their beauty is lost. It is when they are approaching ripeness, or when changing colour and quite dry, that they should be cut, at which time they are sufficiently matured to dry and keep well. After cutting they ought to be laid out thinly on paper or mats and in a sunny position, taking care they do not get wet in any way, and in a few days they will be ready for storing. Some of the sorts are suitable for mixing with cut flowers in vases. Many of the wild Grasses growing in the hedgerows, if collected and dried as

advised in the case of the cultivated kinds, are very pretty and serviceable. W. I. M.

CHRYSANTHEMUMS.

E. MOLYNEUX.

ABOUT this time of the year most growers commence to weed out such plants as are not suited for the growth of large blooms. By this time they will show whether or not they are likely to become suitable for the purpose named, as it is useless to grow on weak or delicate-looking plants, and generally it happens that more have been struck than can be accommodated during summer or housed in autumn. Surplus stock can be devoted to the production of cut blooms, or for conservatory decoration they are equally valuable. Those that are not required for producing large flowers will be from 4 inches to 6 inches high, and must be stopped for the production of side branches, shifting as required into larger pots before they are at all root-bound. Neglect of this often causes a loss of the lower leaves later on in the season. Plenty of space should be given to the plants in all stages of their growth; otherwise, they are likely to become weakly. Flowers can also be had later in the season by growing two batches of plants. One stopping is enough for some, while others should be again pinched when the shoots are 5 inches long, and again when the succeeding branches have attained a similar growth. From that period allow them to grow away naturally, so to speak, thinning no more shoots or flower-buds when they appear. Great care must be exercised in watering the plants in all stages of growth, never allowing them to flag. As the plants increase in size they will require supporting. The best method to adopt is to place three stakes in the pots in a triangular form, and pass around the plant a piece of bast, securing it to each stake. This keeps the shoots in position and is quickly performed. For the smallest plants 8-inch pots are large enough; while for the largest, those 10 inches in diameter are ample. Some upright-growing kinds may be potted two in an 11-inch pot, always selecting plants of the same kind, or those of about the same colour and height. For plants of the smallest size, three or four branches to each are sufficient to retain after the first stopping, but in the larger size about eight is a fair number, and sufficient to produce large bushes, this number being retained at the second stopping, selecting always the strongest, and removing any surplus ones not required. The majority of reflexed varieties have weak peduncles, causing the blooms to hang downward and consequently require support. The largest sorts of the reflexed section are more likely to come with hollow eyes. Where choice can be made, the following will be found suitable, preference being given to those naturally upright in habit:—

Mrs. G. Ruadle
Mrs. Dixon
George Glenny
Venus
Nil Desperandum
Mons. H. Jacotot
Cullingfordi
James Saltor
Flocon de Neige
Bouquet Fait
William Robinson
Simon Delaux
Triomphe du Nord
L'Africaine

Margot
La Nympho
Peter the Great
Eldine
Mlle. Lacroix
Jeanne Delaux
Dr. Macary
Dr. Sharpe
Progne
King of Crinons
Père Delaux
M. Astorg
Fair Maid of Guernsey

Some Anemone sorts bloom profusely and are very attractive, the undermentioned being the best:—

Sœur Dorothée Souillé
Fabian de Mediana
Duchess of Edinburgh
Princess Louise

Fleur de Marie
Minnie Chata
Mme. Goderaux

Where white flowers are in much demand early in October, there is no variety to excel *Lady Selborne*, as its pure white colour is most noticeable while the flowers are full, the florets falling in a weeping manner, and rendering them very suitable for cutting or for conservatory decoration. Plants of this variety grown on the pinching system do not succeed so well. The flowers produced are thin in petal, and appear much too flimsy. To develop its true character it should be grown on what is termed the "big bloom method." Another advantage in this variety is its early blooming propensity. Where space is an object, this variety is particularly valuable, as it can be had in perfection by the 1st of October, and therefore can be cut and the plants cleared away to make room for the regular November varieties. When treated as a bush plant it cannot be so used. Cuttings should be struck at the usual time, or even later, but in this instance the plants probably will not grow so strong. Do not stop the plants, but allow them to break naturally into growth, selecting five of the most promising branches, removing all others and securing those left to a centre stake. When the next break takes place, which will generally be early in August, one bloom bud upon each stem must be preserved. Each of these five stems will produce one flower, which will be in perfection by October 1. Eight-in. or 9-in. pots may be used for single plants, but two, and even three plants may be grown in 11-inch ones. When the plants break naturally the first time, allow three branches only to grow instead of five, as before advised. At the next break select three additional ones to those already formed. In this case remove all the flower-buds and retain the six growths; these will in a short time produce flower-buds, which should be retained one on each stem. Such plants do not require much space, as this sort is upright in growth and not branching in character to the extent that some kinds are. Liberal applications of manure applied in some form should be resorted to either in a liquid state or as a top-dressing.

Single varieties of *Chrysanthemums* are specially suited for conservatory decoration or for supplying cut flowers in quantity. These, to my mind, have not yet had that share of attention which their merits deserve, simply because the rage has all been for the double-flowered kinds, the idea of a single *Chrysanthemum* being quite out of the question. A more lively interest is now being taken in this class than heretofore, owing, perhaps, to the advent of more varied forms, both in colour and structure. They only require to be better known. Here we grew about fifty plants on the bush method, all of which bloomed in the greatest profusion the whole length of the stems, quite 2 feet long, and in some instances more; every little piece of side growth produced several flowers in addition to those on the main stems. These plants were arranged in the form of a sloping bank, intermixing the colours, and the effect was quite charming. Another advantage also, which should not be lost sight of, is the time they remain in flower; being light in the build of the florets, there is not the same risk of damp that there is in the incurved or reflexed sections. By the introduction of a few late-blooming kinds the show can be maintained considerably longer. The perfume, too, from some is like that of *Violets*, only in a more powerful form, and their colours are so varied. For filling centre-pieces they are especially valuable. An instance of this came under my notice during a visit to a November exhibition in the past season. Prizes were offered for the

best decorated epergne composed of *Chrysanthemums* and *Ferns*: in one instance only were the single varieties used, the other competitors depending upon the double, and consequently much heavier kinds. There was no comparison whatever in the stands for lightness of arrangement and beautiful shades, as used in conjunction with the delicate fronds of *Adiantum cuneatum* and *A. gracillimum*. These single va-

plants, covered with their snow-white flowers, in Mr. R. J. Measures' garden at Camberwell.

ORCHIDS.

W. H. GOWER.

ANGRÆCUMS.

ALTHOUGH this family contains a great number of species, the flowers of many of them are small

plant stoves, adding considerably to the attraction of our Orchid collections. The following may be taken as the best and most showy kinds: *A. eburneum*.—This is a noble growing species and appears to have been introduced some sixty years ago, as we find the Messrs. Loddiges recording it as being in their celebrated collection at Hackney in the year 1830, they having obtained it from the Mauritius. In 1854 Mr. Ellis visited Madagascar, and describes this plant as being common upon the branches and in the forks of the trees upon the outskirts of the forests, surrounded with numerous Ferns and other plants; these were flowering in the month of June. In our plant stoves under cultivation, however, the plant flowers in winter. The leaves are strap-shaped, some 18 inches long and 2 inches broad, arranged in a two-ranked fashion, and light shining green in colour. The spike is erect, as long, or longer than the leaves, bearing numerous thick, fleshy flowers, some 4 inches across, which last many weeks in full beauty. The sepals and petals are narrow, green, lip large and conspicuous, cordate in shape and ivory-white. This plant attains considerable dimensions, and is exceedingly ornamental when not in flower. Although it grows naturally upon the branches of trees, it succeeds best in a pot under cultivation. *A. eburneum virens* is similar in size and contour to the preceding, but its foliage is intense deep green; the flowers, moreover, are smaller, and instead of the lip being pure ivory-white, it is tinged with green down the centre. *A. sesquipedale* is found growing in the same districts as *eburneum*, and sometimes they are found in company. In their native habitats they appear to grow in situations tolerably exposed to the sun, and therefore should be well exposed to its influence in this country. Mr. Ellis remarked that where the plants were found growing in shady positions, the flowers lacked their pure ivory whiteness and became creamy or yellowish white, and inferior in beauty; this statement is fully borne out by the plants in our houses treated under the same conditions. Its leaves are broad, two-ranked, and of a peculiar blue-green hue; the flowers are ivory-white, with a fragrance resembling the Madonna Lily, some 8 inches or 9 inches across, flat and spreading; lip very large, cordate-ovate, and acuminate, slightly toothed on the margins, and furnished with a very long and stout greenish spur. It blooms during the winter and early spring months. *Angræcums* require a resting season, but inasmuch as they have no pseudo-bulbs to sustain them during a period of severe drought, water should be administered sparingly and the temperature reduced after growth is finished; this should take place about the time they are in flower. *A. Leonis* is a singular plant of somewhat recent introduction from the Comoro Islands. Its leaves are sword-shaped, set vertically on the stem, and the whole plant resembles a deep green fan. The flowers are borne five and seven together, pure white, and very fragrant, the long spur being tinged with green. It should be grown in shallow baskets and suspended in the strong light, although the full sun's rays should not be allowed to fall upon it through the clear glass. This plant is found at an altitude of some 5000 feet, and appears to thrive under much cooler treatment than the majority of its congeners. *A. caudatum* is still a very rare plant in gardens, although it appears to have been introduced so long ago as 1832. It is a native of the west coast of Africa, in Sierra Leone and Senegal, and consequently requires strong heat and an abundant supply of moisture. Being a compact plant, with leaves some 9 inches or 10 inches long, it can be con-

Angræcum Kotschy.

rieties can easily be grown by following carefully a few simple instructions, which I will give in a future issue.

***Cœlogyne cristata* and *Lemoniana*.**—The former, although an old inmate of our gardens, becomes more popular every year, especially as improved forms of it have recently made their appearance. The variety *Lemoniana*, which is stained in the lip with pale citron colour instead of orange-yellow, generally commences to flower about the time *cristata* is past. We recently saw some very fine masses of these

and insignificant. Of these, *A. distichum*, *teretifolium* and *subulatum* may be given as examples, whilst on the other hand *A. sesquipedale* produces enormous flowers, which rank amongst the largest of any of the Orchid family. They are with but few exceptions natives of Africa or the African islands. During the past few years many new and beautiful kinds have been introduced; these have been successfully established in our

veniently grown in a suspended basket, in which position, moreover, it succeeds the best. The spike is longer than the leaves, pendulous, bearing numerous flowers; the sepals and petals are narrow, spreading, and greenish yellow; the lip which stands uppermost is pure white, furnished with a very long, pendent spur, olive-green in colour. The flowers usually appear during the late summer and autumn months. *A. Chaillanum*, a native of West Africa, from the districts of the Gaboon and Num River, should be treated in a similar manner to *caudatum*, which it somewhat resembles in habit of growth, but from which it is totally distinct when in flower. The racemes are pendent; the flowers are pure white, except the spur, which is yellowish green; the sepals and petals are about equal in size; the flowers somewhat funnel-shaped for about half their length, the upper portion of the segments being reflexed. *A. Kotschyi*, which the accompanying cut well illustrates, is a distinct and free-flowering kind from Eastern Tropical Africa. The flowers are ivory white, with a very long spirally twisted, reddish brown spur. *A. Ellisi* is a somewhat similar plant to the preceding; the flowers are produced in a raceme nearly 2 feet long, bearing from one to two dozen pure white sweet-scented flowers, with a deep brown straight spur 6 inches long. It is a native of Madagascar. *A. bilobum*.—This is a very old, but not well-known plant from the Guinea Coast, West Africa. The leaves are very deep green, slightly netted with prominent veins, and deeply bilobed; the racemes are pendulous, many-flowered, the blooms being snow-white, flushed with pink, and sweet scented; spur slender, some 2 inches long, and slightly cleft at the extremity. This plant is very slow-growing, and requires considerable care in its management. We have tried to grow it under pot treatment, but with little success; neither did it thrive long upon a block of wood, and there is no doubt but the small shallow baskets now in use would suit it best. *A. bilobum Kirki* is a small form of the preceding from the east coast of Africa, and should be treated in a similar manner. The leaves are narrow, about 4 inches long, broadest at the points, where they are deeply and unequally bilobed. Scape drooping, bearing three or more flowers, pure white; spur nearly 3 inches long, light brown. *A. gladiifolium*, although not showy, is admirably adapted for block culture. It is an erect-growing plant with lanceolate, acute leaves; the peduncles one-flowered; the flowers are pure white, nearly 2 inches across, and furnished with a straight, slender spur 3 inches in length. It comes from Madagascar. *A. Scottianum*, from the Comoro Islands, is a terete-leaved plant somewhat resembling a small form of *Vanda teres*. The lip is large, and the most conspicuous part of the flower, which is pure white, saving the spur, which is greenish brown, tinged with yellow, and some 6 inches long. *A. pellicidum*, although not particularly showy, is an extremely handsome plant, bearing large broad leaves, from 12 inches to 18 inches long, and somewhat resembles a gigantic *Phalenopsis grandiflora*. The racemes are numerous, as long, or longer than the leaves, and thickly clothed with thin pellicid white flowers. It may be grown upon a block when small, but should be placed in a basket as it increases in size. It is a native of low districts on the west coast of Africa, and enjoys an abundance of moisture and strong heat. *A. fastuosum*, from Madagascar, is a handsome plant, with ivory-white flowers, which are very fragrant. *A. fuscatum*, also from Madagascar, produces a dense-flowered raceme of white flowers, furnished with a long, curved, slender spur. *A. citratum* somewhat resembles

in growth *Phalenopsis rosea*, and produces in mid-winter numerous long, slender, pendulous racemes, densely covered with small, flat, white flowers tinged with citron; spur longer than the lip, rather blunt, pale yellow at the extremity. It comes from Madagascar, a country which appears to abound in handsome forms of this genus. It should be grown upon a block of wood or in a shallow basket, and suspended from the roof. *A. falcatum* is a native of Japan, and thrives best on a block of wood, and should be grown in the *Odontoglossum* house. It is a small plant with very dark green leaves, producing its racemes very freely, which are densely furnished with its pure white, long-spurred, fragrant blooms. Other fine kinds are *A. elatum*, *articulatum*, *descendens*, *Eichlerianum*, *pertusum*, &c.

Angræeums require considerable care to maintain them in good condition, and are, perhaps next to *Phalenopsis*, the most difficult Orchids to cultivate. They enjoy a high temperature and an atmosphere well charged with moisture, but a free circulation of air must also be maintained. A season of rest is necessary to induce them to put forth their blooms in due season, but they cannot withstand much drought, which injures their foliage, except in the case of the large growing kinds with thick leathery leaves, which are less susceptible. In order to meet these requirements, it will therefore be found most conducive to their well-being to reduce the water supply, both to their roots and in the atmosphere, and to lower the temperature rather than to maintain strong heat and severe drought. This resting period should be about the time they are flowering, and as the majority of the kinds are winter bloomers, this course of treatment can be easily applied. For those grown upon blocks of wood, a little *Sphagnum* Moss about their roots is all they require, but for those in pots and baskets, we have found some good-sized lumps of rough peat and nodules of charcoal to suit them admirably, whilst thorough drainage is of the most vital importance.

Cymbidium eburneum.—This very fine species is now in bloom in Mr. Williams' nursery at Holway. It is a large-flowered variety, and bears two flowers on some of the scapes; the sepals and petals are pure white, as is the entire flower, except a slight stain of yellow on the lip. This species obtained the reputation of being a shy bloomer until its wants and requirements were understood. Formerly it was kept in the very hottest part of the East Indian house, but now, when grown in a cool house, it flowers freely.—G.

Lælia elegans Measuresiana.—This is a new and distinct variety, which we recently saw blooming with Mr. Sander at St. Albans. The plant is robust in growth, and has nothing, either in pseudo-bulb or leaf, to distinguish it from the type. The flowers, however, are both distinct and handsome; sepals and petals clear sulphur-yellow, the latter flashed with purple at the tips; lip broad; front lobe rich, deep velvety purple; side lobes rolled over the column, and pure white in colour. The typical *Lælia elegans* is a rare plant in its native country, and the quantities of it that are imported are not large; consequently, its varieties, especially such a beautiful one as this, are not plentiful.—G.

Cœlogyne cristata.—Mr. Page, in THE GARDEN (p. 275), March 26, says that the bulbs of this produced under cool conditions were small. I leave that for you to judge, as I have sent you a sample of bulbs so grown. I also remember that two of my largest plants in pots each 1 foot across, which were taken more than twelve months ago from the cool house some time after the bulbs were made and placed in the East Indian house to get a few early flowers, had respectively twelve and sixteen spikes of four, five, and six flowers each. Requiring more room last

spring in the *Masdevallia* house, I shifted them into warmer quarters, viz., the back stage of one of the lean-to houses. The bulbs they made were about the same, with, I am sorry to say, a tithe only of the flowers they produced in the cool house.—H. VICARY, *Sudbury House Gardens, Hammersmith*.

* * * The bulbs received were large and plump, and certainly showed that under cool treatment these plants will do well.—ED.

— In reference to Mr. Page's remarks on this beautiful Orchid in THE GARDEN (p. 275), March 26, a few years ago I saw a batch of this Orchid at Wortley Hall that had been grown under what might be termed cool treatment, as heat was only applied in cold or dull weather. The plants were flowering very freely, and many of them had two spikes from each bulb, several of the spikes having seven flowers on each. One plant growing in an 8-inch pan had fifty spikes on it.—C. R., *Seelberg*.

ORCHIDS AT WILTON HOUSE.

THE Orchid houses in these gardens are very gay just now, nearly a hundred species and varieties contributing to the display; amongst this number are some very notable plants. *Odontoglossum Edwardi*, the first plant that flowered in Europe, is bearing a spike some 4 feet in length, with a much-branched panicle carrying upwards of a hundred and fifty blooms; the individual flowers are over an inch across, and a deeper shade of violet-purple than we have hitherto seen; the peculiarity of its colour added to its fragrance renders this a great acquisition. It is a native of high mountains in Ecuador, and appears to grow robustly under the very coolest treatment. *O. roseum* is another departure from the usual colour of the genus, and its rosy crimson flowers are now conspicuous among numerous forms of *O. Alexandre*; it also requires a very cool atmosphere. Associated with these are some fine examples of *O. triumphans*, *pulehellum majus*, *Sanderianum*, *maculatum*, and others. Of *Oncidium*s, *O. Weltoni* is very conspicuous, with a spike about 3 feet long bearing upwards of fifty flowers; it is now relegated to the genus *Miltonia*, and is known as *M. Warscewiczii*. It comes from the cool regions of Peru, and thrives well with *Odontoglossum*s of the crispum section. In the same house are some of the finest forms of *O. Phalenopsis* we have yet seen, the flowers being very large and highly coloured; the markings varying in the different forms from blotches and spots of maroon-erimson to purplish violet. We also noticed that in some plants the lateral sepals were joined together (connate) for their entire length, whilst others were free, except at the base. This species, with its near relative *O. eucallatum*, cannot well be kept too cool. *O. sarcoades*, a Brazilian plant which requires more heat than the preceding, is here represented by a fine variety bearing a spike of nearly eighty flowers. The variations in *Lycaste Skinneri* are very great; indeed, these plants are quite an exhibition in themselves, several of them bearing over fifty flowers upon a plant. These have for several years been grown upon the cool plan, and have become grand specimens. In the warm house *Dendrobium*s are very gay, being represented by such kinds as *Wardianum*, *Devonianum*, *lituiflorum*, *crassinode*, *primulinum*, and others, all of which have remarkably fine growth. *Jamesianum*, in particular, has pseudo-bulbs 2 feet in length, bearing as many as twelve flowers on each stem, the ivory-white sepals and petals being beautifully set off by the stain of red at the base of the lip. *Cypripedium*s are well represented in this collection, the most noteworthy example at present in flower being *Dominianum*, with seven spikes of its long-petaled flowers. *Cymbidium Lowianum* and *eburneum* are both extremely beautiful, as also are various *Cattleya*s, but the winter-flowering section is now on the wane. *Masdevallias* are not yet at their best, but good examples of the brilliant *Vcitchiana grandiflora* are in full beauty, associated with *ignea* in various forms, *amabilis*, *Harryana*, and *Chelsoni*. Many other kinds are now flowering of less importance.

Suffice it to say, the cool treatment of all the species both from the eastern as well as the western hemisphere is carried out here, the condition of established plants and seedlings proving how congenial this is to their well being. G.

Dendrobium fimbriatum Will some one inform me how to cultivate this beautiful Dendrobe? I have three plants under my care which fail to bloom satisfactorily. They are grown in a stove with Crotons, Gardenias, and other fine-foliaged plants which do well. They are potted in peat, crocks and charcoal; one has made growth 3 feet in length, and one of the others 2 feet to 3 feet; yet I have only one spike of bloom each on two of the plants. I put one plant in a cool house in December and kept it dry for two months, so that the growths began to shrivel.—ALBERT PARRY, *Shendish, Hemel Hempstead*.

Odontoglossum triumphans—This species, which is now flowering with Mr. Jacomb, at Stamford Hill, appears to have been very much neglected by Orchid growers, the reason for which it is difficult to imagine. It is a bold-growing plant producing a many-flowered raceme of bloom, the individual flowers being upwards of 3 inches in diameter, sepals and petals broad, rich deep yellow, more or less profusely blotched with chestnut; lip large, white at base, but deep reddish brown in front, the toothed crest being also white. It is usually a late spring and early summer flowering kind, but it is now in fine condition in this collection, and affords a rich contrast to the white flowers of *O. Alexandre* and *O. Pescatorei*. Its flowers are very persistent; it may be grown successfully under the same treatment as the coolest of the *Odontoglossums*.—G.

Cypripediums at Clapton.—Amongst the thousands of Lady's Slipper Orchids which Mr. Low has in his nursery some very good examples are now flowering. Trade collections, however, can never be so effective or showy as the collections in private establishments, for whilst the latter conserve, the former are only too anxious to distribute the gems. *C. Lawrenceanum*, conspicuous and handsome by its remarkably marbled leaves, is doubly attractive when in bloom, its large and showy flowers having few equals in the section to which it belongs. *C. villosum* and *C. Boxalli* are represented by many examples. *C. Lowi*, although early in the season, is just beginning to unfold its lovely blossoms. *C. Haynaldianum*, which somewhat resembles *C. Lowi*, is also in fine form, and blooms twice in one season. *C. Swainianum*, which is a hybrid between *C. Dayanum* and *C. barbatum*, is both distinct and handsome, the beauties of both parents being happily blended; whilst *C. Sederi* and *C. Roezli* appear never to be destitute of flowers.—G.

SHORT NOTES.—ORCHIDS.

Phalenopsis Schilleriana.—This species is now to be seen in great beauty in Mr. Bonny's nursery, near Swanley. The plants are in most vigorous health, producing numerous branching spikes, each bearing from twenty to thirty of their beautiful mauve-coloured blooms.—G.

Odontoglossum cuspidatum.—This is a very distinct and handsome species; the sepals and petals are soft primrose-yellow, blotched with chocolate; the lip is white, tapering gradually to a sharp, stiff point (cuspidate), and spotted with dark brown. We recently noticed it blooming in Mr. Williams's nursery at Holloway.—G.

Ada aurantiaca.—This is a free-growing Brassia-like plant, and requires very cool treatment. It bears a nodding raceme of bright cinnabar flowers, rendering it very attractive and useful for arranging with light-coloured flowers. We recently saw it in quantity flowering in Mr. Bull's nursery at Chelsea.—G.

Dendrobium micans.—This hybrid is now flowering with Messrs. Veitch at Chelsea. The growths measured 3 feet in length, and are well furnished with 1 vely tinted flowers. The sepals and petals have a bluish tint suffused through the pale purplish colour; in the centre of the lip there is a dense purple-maroon blotch. This has been raised by crossing *D. Wardianum* with *D. lituiflorum*.—J. D.

Phalenopsis Stuartiana.—A seedling *Phalenopsis* now in flower in Messrs. Veitch's nursery at Chelsea has proved to be the same as the imported *P. Stuartiana*. It was raised by crossing *P. Schilleriana* with the pollen of *P. amabilis*. The white petals, the peculiar spotting and formation of the labellum is the same. This is one more problem solved. It will be remembered that the parentage of *P. casta* was verified by the flowering of a hybrid raised in this nursery.—J. D.

Paphinia Randi—This is a new species of this curious family which we recently saw flowering with Mr. Williams at Holloway. It is about the same size as *P. cristata* both in growth and flower; the sepals and petals are deep chocolate-brown, with a narrow marginal border of white, the lower sepals being streaked irregularly with broad lines of white; the lip is deeper coloured with a white frill, but differs in shape to any other species we have seen.—G.

CALANTHES AND THEIR CULTURE.

It would be quite impossible to name any plants or bulbs which bloom so freely in the late autumn and early winter months as the *Calanthes*. Their long arching spikes are most graceful, and the form and colour of the blooms of all the varieties are charming. In many cases, plants which are well grown and promise to bloom freely are shy in making a display. Careful spring and summer culture will always result in abundance of flowers during autumn and winter. The bulbs are perfectly at rest during the blooming season, especially towards the end of it, and the best treatment they can receive until March is to keep them quite dry. They ought to be started into growth again in March. The growths push forth from the bottom of each bulb, and we have seen them appear whether the bulb was planted or not, but one of the best ways of treating them we ever tried, and which we now follow, is to place the bulbs in a layer in a shallow box; stiff between them firmly with Moss to the depth of 2 inches, place them in a warm house, and allow the growths to break in this way. The short roots penetrate the Moss, and the growths push freely through it. When these are about 2 inches in height they are lifted carefully, without breaking root or top growth, and potted. We have potted them in all sized pots, sometimes placing four or five bulbs in an 8-inch pot, or three in a 7-inch pot; but of all ways, we have invariably found the best to be that of potting the bulbs singly in 6-inch pots. They are put into these and never shifted or repotted afterwards. Careful potting is the secret to their successful culture, and we attribute more to it than anything else. The roots are rather fleshy and produced in great abundance, consequently they require plenty of drainage and a rough mixture. Mere quantity of drainage is not the only point, as a pot containing one quarter of drainage at the bottom carefully arranged is more effectual than another half filled, but improperly arranged. We have used oyster-shells for draining *Calanthe* pots with good results, but whatever is used should be lumpy and not liable to get choked up. The potting compost should consist of little fibrous lumps of peat and loam in equal parts, charcoal and sand, and a few rough horse droppings. After the bulk of it has been mixed up, and before adding the sand, it is a good plan to give the mixture a shaking in a sieve, to remove all the small material, as small stuff is not only useless, but injurious, and hinders their progress. After draining the pots, a quantity of the potting mixture should be put over the drainage. Make it very firm, and rest the bottom of the bulb on it; filling up all round should then be done, making it firm, and finishing off with the bulb about one quarter above the soil. I approve of keeping them pretty well under, as when the pot becomes full of roots, the bulb is apt to become displaced if not given a good hold of the soil at first. There is another important point. When potting is finished, many would be inclined to finish off with a good watering at the root, but this is the worst practice that could be followed, as they are very slow in starting into growth in a wet soil, and do not root half so freely and quickly as in a rather dry soil. Some six or eight years ago I visited a first-rate *Calanthe* grower, who had shown me on previous occasions some of the best bulbs and spikes I had ever seen, and after showing me many other good things, I inquired: "Where are your noted *Calanthes*?" He informed me that the man in charge of them had watered them too early, and ruined them for the season. The atmosphere in which they are placed may be—in fact, must be—damp, and the syringe used over and under them, but keep the watering-pot away until a number of roots have

been formed and they show signs of growth. When growth is active, water without stint, give manure water frequently when the pots are full of roots, and as soon as they can bear exposure to the sun, place them in a moist atmosphere where the temperature averages 70°. CAMBRIAN.

FERNS.

W. H. GOWER.

ASPIDIUM.

This name comes from "Aspidos," in allusion to the indusium being round like a buckler or shield, and hence the vernacular name for this genus is Shield, or Buckler Ferns. These names are also frequently given to the plants belonging to the genera *Lastrea* and *Polystichum*, but are only applicable to them when they are treated as *Aspidiums*. The plants belonging to this genus are characterised by their erect habit of growth and by their fasciated fronds, which are usually twice or more or three-times divided, the segments being more or less lobed. The veins are compoundly reticulated (not free, as in *Lastrea* and *Polystichum*), and the indusium is orbicular, with the attachment in the centre. The most of the plants included in this family produce bold and massive fronds. They are very effective when grown into specimens, either as pot plants or planted in a fernery constructed on the natural system. The species appears to be somewhat widely distributed over the islands and mainland of the tropical portions of both hemispheres, but none are found in Europe. Notwithstanding their being natives of the Tropics, they are robust and vigorous in constitution, their stout and leathery fronds enabling them to stand a somewhat low temperature unharmed. The following are the most showy and distinct kinds in cultivation: *A. latifolium*, known also by the name of *nigripes*, is a native of the Fiji Islands. The fronds are from 1 foot to 2 feet in height and about 8 inches broad; the stems jet black and naked for about a third of their length, the crown of the plant and the base of the fronds being furnished with numerous black chafly scales. The fronds are membranous in texture and deep green, pinnate in the lower half, the pinnæ more or less deeply divided into broad acute segments; the upper portion only deeply lobed. It is one of the handsomest and most useful species. *A. Barteri* is a native of West Tropical Africa and requires strong heat; its fronds are from 1 foot to 2 feet in height, once-divided and bearing from two to three pairs of segments beside the terminal one, which is the largest. The segments are winged to the midrib (pinnatifid), lengthened out into tail-like points and bright green. *A. Pica*, also known as *ebenum*, in allusion to its black stems (but this designation is equally applicable to *latifolium*), is a bold growing plant, but dwarfed than the majority of *Aspidiums*, seldom exceeding 1 foot in height, and 5 inches or 6 inches in breadth. The fronds are usually more or less deeply lobed, none of the lobes being divided to the main stem (rachis); upon rare occasions, however, we have observed them pinnate in the lower part, having a single pair of lobed segments at the base, in which condition it somewhat resembles *trifoliatum*; but its ebony-black stem renders it easily distinguishable from that species. It forms a handsome specimen when grown in a pot, and is also very effective planted in a prominent position in the rock-fernery, not too far above the line of sight. It is a native of the Mauritius and grows freest in stove heat. *A. coadunatum* is a handsome Fern from Ceylon, producing fronds from 2 feet to 3 feet long, and

6 inches to 8 inches broad; the stems are brown, bare for about a third of their length. The fronds are somewhat triangular in outline, the upper portion pinnate, having the lobes divided about half-way down; the lower pair of pinnae, however, are again divided on their inferior edge, whilst the colour is bright cheerful green. In *A. repandum* the fronds are about 18 inches high, pinnate in the lower part, the basal pair of segments being one-lobed on their inferior edge, but the upper ones are winged with the stem at their base. They usually bear five or six pairs of pinnae and a terminal one, each being about 5 inches in length, with smooth edges, deep green in colour. It comes from the Philippine Islands. *A. subtriphyllum* is a handsome species, a native of Ceylon, the fertile fronds usually somewhat narrower than the sterile ones; the stems are naked for about half their length, fronds oblong in outline, the terminal pinnae forming the greater part of the whole; this is obtusely lobed, and tapers to a point; at the base are a pair of pinnae entirely separated from the terminal one, these again being lobed on their inferior edge. They are deep green in colour, and bear copious dark brown sori. *A. variolosum* is a plant which closely resembles the preceding and also comes from Ceylon. *A. decurrens*, another Ceylon plant, produces fronds of two kinds; in the very young state the sterile ones are simple, but as they increase in size they produce a single pair of obtuse lobes a little below the middle; these infertile fronds are from 6 inches to 12 inches high, and 2 inches to 3 inches broad, undulate at the edges and deep green. The fertile fronds are very distinct and about double the size of the sterile ones; they are deeply pinnatifid, bearing four or five pairs of segments and a terminal one. These segments are distant, and are connected with each other by a very narrow wing running down the stem; they are 6 inches long and upwards of an inch broad, obtusely notched, the lower pair being again once-divided on their lower edge. The sori are very copious, large and conspicuous. *A. Pteropus*.—This is said to be a variety of the preceding, but under cultivation it is very distinct; it produces fronds of two forms, the sterile ones being broad, deeply pinnatifid and lobed, whilst the fertile ones are very much narrower, the decurrent segments being less than half an inch wide. It is sufficiently different in aspect to be grown side by side with *decurrens*. It is a native of Ceylon. *A. Plumieri* is a massive, bold Fern from Jamaica, making fronds from 18 inches to 2 feet in height, and from 8 inches to 10 inches wide. It bears one pair of pinnae at the base, these being obtusely lobed on the lower edge; the terminal segment also is once pinnatifid at the base, 4 inches across, the ends being lengthened out into tail-like points, deep green on the upper side, sori copious beneath. *A. trifoliatum* in its immature form somewhat resembles *A. Pica*, and when fully developed it assumes very much the appearance of *A. latifolium*; from these, however, it may be distinguished at a glance by its brown (not black) stem; it has derived its name from usually bearing one pair of pinnae and a terminal one, all of which are deeply lobed and undulated on both edges; it, however, not infrequently bears a middle pair of pinnae in addition. It is of a rich, deep green on the upper side, profusely ornamented beneath with large conspicuous sori. It also bears the name of *heracleifolium*. It is a native of Jamaica and various other West Indian Islands, and is a very hardy plant. *A. cicutarium* is an elegant species, more finely divided than any of the

preceding. The fronds are from 18 inches to 3 feet high, somewhat triangular in outline, bipinnatifid, and pale green with obtuse segments. It comes from the West Indian Islands and Tropical America. The above-named Ferns are by no means fastidious in their requirements, most of them being easily grown into good specimens in the temperature of an intermediate house, although it cannot be denied but that they become larger and more fully developed in stronger heat; their fronds, however, are sufficiently thick and leathery to enable them to stand for a very long time in the dwelling-house without any heat, and thus the majority of them are available for the embellishment of any place where broad, massive fronds are required. If these plants have not yet been repotted this season, no time should be lost in doing it, as the young fronds are now pushing up; more care is necessary perhaps in repotting broad-fronded Ferns than any others, because any deformation which comes about through injury to the roots is more plainly discernible. They should be potted in peat and loam in about equal parts, adding some sharp river or silver sand. Being strong-growing plants they require ample pot room. They enjoy a copious supply of water, and a little application of soot greatly assists the colour of the fronds.

Stenosemia aurita.—This is the name of a very handsome, but by no means common, plant belonging to the reticulated-veined section of the *Aerostichoid* Ferns, and is nearly allied to the genus *Polybotrya*. The fronds are of two distinct forms, although sometimes we have seen them intermediate in character. The sterile one is a foot or more high, triangular in outline, and somewhat resembles *Aspidium trifoliatum* in general appearance. It bears a little bulbil on the stem at the base of the lower pair of pinnae, which eventually forms a young plant; it is leathery in texture and deep green. The fertile frond is about the same height as the sterile one, and the divisions are similar, but instead of being broad and leafy, they are all reduced to narrow, linear segments, which are completely covered with brown sori. This makes a neat and compact specimen in the stove, and is by no means a delicate plant; it usually produces its fertile fronds annually, and when thus furnished it becomes a most attractive object. Pot in peat and sand, using small pots. It is the only species in cultivation, and is found in various islands in the Eastern Archipelago.—G.

Trichocarpa Moorei.—This is a remarkable and handsome Fern from New Caledonia. It is named in honour of Mr. Charles Moore, director of the Public Gardens in Sydney, and is the only species yet discovered. Hooker places it in the genus *Deparia*; from this genus it is, however, very distinct, and easily distinguished by its reticulated veins, those of *Deparia* being forked and free. The fronds rise from a short decumbent root-stock, and seldom exceed a foot in height. They are triangular in outline, twice or thrice-divided (bi-tripinnatifid), membranous in texture, and bright green in colour. A characteristic feature of this plant is the peculiar hair-like veins, which extend beyond the edge of the fronds and form footstalks, which support little cup-shaped receptacles, in which the sori are situated. This forms a neat and handsome specimen in a stove temperature. Care must be taken in watering it, however, as if wetted overhead its fronds lose their brilliant green colour. It should be potted in peat and sand in small pots with plenty of drainage.—G.

SHORT NOTES.—FERNS.

Juan Fernandez Fern (*J. C. Bristol*).—Your Fern is *Thyrsopteris elegans*, a species peculiar to the island of Juan Fernandez, but we believe it is by no means plentiful there. It is the only species known, although it would appear to have some affinity with *Balanium culcita*, a native of the Azores and Madeira. It is a plant very seldom met with, although it has been in cultivation for some years. In its native country it is said to rise upon a slender stem, and is

found in mountainous districts growing in moist shady woods. The sterile fronds somewhat resemble a gigantic form of *Davallia canariensis*, but when fertile the lower pinnae of the fronds are reduced to rachiform segments, bearing the large cup-shaped involucre. It would certainly be worth importing.

Llavea cordifolia.—This is a singular and handsome Mexican Fern, which appears to be nearly allied to *Allosorus* and *Gymnogramma*, although totally distinct from either. It grows some 18 inches or 2 feet in height, and is three-times divided, the sterile segments being stalked, oblong, or ovate-cordate in shape, finely toothed on the edges, and from 1 inch to 2 inches long. In this state the fronds much resemble small specimens of *Osmunda palustris*. When fertile the whole upper portion of the frond becomes altered in appearance; the segments are narrow, linear, and pendulous, from 2 inches to 3 inches in length and pinnulate, with the margins rolled inwards, forming a universal indusium, which nearly encloses the sori. The whole plant is of a pale green hue, and the stems (especially towards the base) are profusely clothed with large white chaffy scales. It should be grown in small well-drained pots in peat, loam, and sand, and placed in a somewhat cool, but not cold house. This plant is also known by the name of *Ceratodaetyle osmundoides*. We recently noted fine examples of this Fern in Mr. Laing's nursery at Forest Hill.—G.

GARDEN FLORA.

PLATE 591.

THE PURPLE GUM CISTUS.

(*CISTUS PURPUREUS*,*)

THIS is one of those delightful shrubs that are classed among what are called old-fashioned flowers, and very old it is, seeing that it was cultivated in England as far back as 1550, and was cherished and loved by Gerard, Parkinson, and other fathers of English gardening. It therefore possesses much interest as well as exquisite beauty, but for all this it is not in common cultivation, being found only in gardens where old-fashioned plants abound and in botanical collections. There is, however, some allowance to be made for these, because this and most all other species of *Cistus* are unquestionably tender, only thriving to perfection in the warmest gardens in this country and on the lightest of soils. But there are numberless gardens along the coast and in other warm localities where all the Gum *Cistus*es and Sun *Roses* (*Helianthemum*) would thrive and create an effect totally different from all other shrubs, and even where they cannot be grown in the open they would flourish against a sunny wall, and how could a wall be more beautifully clothed than with these sun-loving shrubs. The best of all spots for them is a sunny knoll, open to the south and well sheltered to the north and east. The place must be well drained and the best soil is a deep sandy loam. In such a spot one could plant the best of the tall *Cistus*es, and fringe the group with the dwarfier species and the finest kinds of *Helianthemum*.

The finest of the *Cistus*es include, besides *C. purpureus* (a good coloured plate of which is here given), the following species: *C. ladani-ferus*, which grows about 4 feet high and has large white flowers; *C. crispus*, flowers purple; *C. hirsutus*, white flowers, golden centres; *C. salviifolius*, large white flowers; *C. monspeliensis*, white; and *C. laurifolius*, a very hardy species, with Laurel-like leaves and white flowers. These are all natives of the south of Europe and all evergreen bushes, producing an abundance of flowers generally in the height of summer. Though the blossoms are very short-

* Drawn for THE GARDEN by Miss Lowe, at Woodcote, August 18, 1886, and printed by G. Severeys.

THE GARDEN

lived, they are produced in such profusion and in such quick succession, that their short duration is not noticeable. Some of the species named are deliciously fragrant, particularly *C. laurifolius* and *ladaniferus*. In every good garden where the climate is favourable there should be a spot set apart for a group of Rock and Sun Roses; and where space cannot be afforded for a distinct group, they should be planted here and there about bold rockeries.

W. G.

STOVE AND GREENHOUSE.

THE HYACINTH.

WE are now in the height of the Hyacinth season, and the gorgeous displays to be found in most gardens are proofs of the great popularity of these beautiful spring flowers. They have become during the last decade almost as important adjuncts to the numerous spring exhibitions as the *Chrysanthemums* are to those of autumn or winter. As a rule the trade exhibitors display their plants to the best advantage, but the opposite of this holds good as regards amateur collections. In many instances the plants are not well grown, and where placed for exhibition the arrangement of the plants leaves much to be desired. An instance of this might be found in the exhibits at the Crystal Palace, where the trade exhibitors made an excellent display, but the whole of the amateur growers failed to satisfy the judges that their exhibits were of sufficient merit to obtain the highest awards offered. As a successful exhibitor of the Hyacinth, I will offer a few remarks on its culture that might be of service to those intending to exhibit in the future. In the first place, it is necessary to obtain the best bulbs, which may cost a little more money, as they should be four years old. They must have careful cultivation, for everyone knows that the grower in this country cannot produce large spikes unless the rudimentary part is formed in Holland the previous year. Our object is to get the largest amount of beauty from them by developing the spikes and flowers perfectly. The Hyacinth requires good open soil to grow in, and in order that the compost may be well incorporated, we mix it up about three months before it is required—loam two parts, decayed cow manure one part, one part leaf-mould, and one part coarse sand. The bulbs are potted about the third week in October, one in the centre of a 6-inch pot. They are potted so that the crowns are left above the surface, the bulbs being pressed in moderately firm. When they are all potted arrange them close together out of doors on a hard bottom of ashes, and cover them well over with some Cocoa-nut fibre refuse. There let them remain to allow them to form roots until the middle of January, when they may be taken out and placed, in the first instance, in a cool house and removed to a warmer temperature if necessary to hasten their flowering. The spikes develop very rapidly after this, and require manure water frequently to bring them to perfection.

As the spikes develop they must be supported in some way. The best support is a stout iron wire bent at the base, to avoid injuring the bulb; the upright wire is worked in amongst the bells, so that it is not seen at all when the plants are arranged in the exhibition, the greenhouse, or conservatory. The best spikes for exhibition are those on which the bells are closely arranged, so that they form a very compact, symmetrical head of bloom. As a rule, the bells do not take this form naturally, but require some little arranging with an ordinary pencil. It can scarcely be called dressing, though some critics say it is, but whether the plants are required for exhibition or merely to be arranged in the greenhouse, this is a necessary part of their culture, and those who object to assist the natural habit of the plant in this way must be content to take a lower place. A spike with the bells drooping is not nearly so effective as one with the bells arranged in a horizontal position. A very important matter is the

selection of varieties. The catalogues enumerate a much larger number than is really required, and as many new varieties gradually find their way into cultivation, the difficulty of selection every season becomes greater instead of less. I have before me a catalogue of an extensive Dutch grower, in which are enumerated 120 double varieties, most of them having very fascinating descriptive remarks attached. At one time double Hyacinths were the most popular. Now they are not much esteemed. For exhibition purposes they are, with one or two exceptions, worthless. The only double varieties we care to grow are the following: *Laurens Koster*, indigo-blue; *Louis Philippe* and *Van Spayk*, pale blue; *Koh i-noor*, salmon-rose; *Princess Louise*, red; *Lord Wellington*, pale rose; and *Miss Nightingale*, white. The same catalogue enumerates 236 single varieties. It is far too many, and those wishing to select their own bulbs must have great difficulty in doing so unless they have some personal knowledge of the varieties. Amongst newer varieties to be obtained at a higher price than the older well-known sorts, *King of the Blacks* has been very fine this year, and is certainly the best blue-black variety, and produces a more handsome spike than the old variety *General Havelock*. It is superior to *Masterpiece*, which does not produce a long spike. The best of the older dark blue varieties are *King of the Blues*, *Marie*, *Souvenir de J. H. Veen*, and *Mimosa*. There are now some very handsome light blue varieties; *Electra* and *Princess Mary* of Cambridge are amongst the best of the newer ones obtainable at a reasonable price. *Lord Derby* took the lead this season as the best light blue. These, with *Biondia*, *Czar Peter*, *Grand Maitre*, and *Lothair*, are the best. The good old variety *Grand Lilas* must not be omitted. Amongst the darker red varieties, *Vurbaack*, rather expensive, is still the best. *Linnaeus* is very distinct and beautiful; *Etna* is a handsome new variety, forming a massive spike; *Lina*, *Von Schiller*, and *Prince Albert Victor* are very fine. Amongst pale red or rose the best are *Cavaignac*, *Fabiola*, *gigantea*, *Princess Amelia*, and *Grandeur à Merveille*. In the single white class, by far the best is *La Grandesso*; next to it is *Mont Blanc*. *Alba maxima* and *alba superbissima* may also be grown, but I do not care for any others. *Sir Henry Havelock*, *Haydn*, and *Jeschko* are mauve tinted, and may be grown for variety.

The best yellow as yet is *Ida*, but *King of the Yellows*, *Bird of Paradise*, and *Obelisque* may also be grown. Those who would like to grow a larger selection may find no difficulty in obtaining them; but intending exhibitors would do well to select a larger number of bulbs of the above rather than grow a greater variety, which may fail them on the day the plants are wanted.

J. D.

How plants fared in a cold house during the winter.—I have no doubt that there are others who, like myself, have had to experience great losses of plants from frost in a cold house during the past winter. The slaughter has been unprecedented. My house is about 24 feet by 10 feet, a lean-to on the south side of the dwelling, having a flooring of thick slabs of slate, which are about 5 feet from the garden level and fully open underneath. Thus the frost attacked the house not only on three sides and the roof, but through the flooring also. I gave up *petroleum* stoves two or three years ago on the ground that they were dirty and disagreeable, on account of their fumes, expensive and useless. All that I could do in the way of precautionary measures was to allow the plants to become fairly dry at the roots, keeping the interior of the house, and especially the shelves, quite dry, and covering up with newspapers as securely as possible. Alas! all was in vain. Not a *Fuchsia*, large or small, remains alive, and not a zonal *Pelargonium* either. The plants were of various sizes, but all came to grief. Large well-established specimens of *Agapanthus umbellatus* are very much shaken; good plants of *umbellatus albus* and *variegatus* are all dead, and not a *Richardia aethiopica* saved. *Primula obconica* and *floribunda* soon went; a *Beaucarnea* that I had kept through three winters

succumbed; and in its wake went *Eupatoriums*, *Scilla longibracteata*, *Cannas*, &c. Some large plants of *Eucalyptus globulus* are well-nigh destroyed. Of those saved there is a pretty Indian *Azalea* that looks as fresh and full of buds as if it had been kept in a warm greenhouse all the winter. A good piece of *Phormium tenax variegatum* is damaged certainly, but not much disfigured; *Begonia metallica*, *Plumbago capensis*, some fine plants of *Pachyphytum bracteosum*, *Agave americana*, and *A. picta* are saved. There appears to be something peculiarly destructive about the wintry weather in January and February. For some ten years past, and even through the bitter time of January, 1881, I had managed to save soft-wooded things, such as zonal *Pelargoniums* and *Fuchsias*. I shall make no further attempt; when autumn leads the way for winter they will be thrown away to the rubbish heap, as unworthy the care required to bring them safely through the winter in an unheated structure.—R. D.

THE FAMILY LABISIA.

THE genus *Labisia*, which belongs to the Natural Order *Myrsinaceae*, is very little known at present in cultivation, owing, no doubt, to the fact that its representatives are few, consisting of only three or four species, which are all natives of the Malay Archipelago, singling out Borneo as their chief habitat. The plants of this genus are known under the not very popular name of "Spoon-flowers," on account of the lobes of the corolla, which resemble the bowl of a spoon. As regards systematic arrangement, it is a near ally of the well-known genus *Ardisia*, which has contributed so many beautiful plants to our collections.

The genus is represented in gardens now by three species, viz., *L. Pothoina*, *L. alata*, and *L. Malouana*. The first and earliest known, *L. Pothoina*, has been in cultivation more than forty years. It is a stove plant, having the habit of a *Pothos*, as its specific name implies, and thrives in a humid atmosphere. It has sessile leaves swollen at the base and small white flowers. *Ardisia pumila* is a synonym of this plant.

L. ALATA is a pretty soft-wooded stove plant, which may be readily distinguished from the preceding species by not having the leaves sessile, but clasping the stem by means of a very short dilated petiole. The graceful habit of the plant is due to the pretty spreading leaves, which are contracted at the base. The colour of their upper surface is glaucous green, while the under surface is of a dull green. The flowers are small, white inside, red on the outside, and arranged in small clusters on the flower-spike.

L. MALOUANA is quite a recent introduction, and is named in compliment to M. Jules Malou, a French botanist. It is a pretty ornamental stove plant with woody copper-coloured stems, profusely covered with small white warts, which give them a variegated appearance. The leaves are entire, ovate, and, like *L. alata*, clasp the base with a short dilated petiole. The upper surface is dark green and velvety, with a light green mid-rib, gracefully ornamented on each side with a broad band of a leaden-white colour. This band is composed of numerous minute spots lying very close together, and give the central portion of the leaves an appearance as if flour had been sprinkled over them. The under surface is reddish purple on each side of a brownish red mid-rib, but assumes a green colour adjoining the margins. When the leaves are young they are smooth and shining and of a reddish purple hue. The chief attraction of this species lies in its compact habit and ornamental foliage, characters which cannot fail to recommend it. A plant may now be seen in flower in the stove at Kew. A. Z.

Anopteris glandulosa.—This is a greenhouse shrub belonging to the once popular, but now neglected class known as New Holland plants. It is rather a sturdy growing bush, of erect habit, with very dark green leaves of a stout, leathery texture some 6 inches or 8 inches long, while the flowers, which are borne in terminal racemes, are bell-shaped, and of a white, wax-like character, reminding one to a great extent

of some of the Andromedas. Though it attains a good size in its native country, this *Acropteris* will flower freely enough in a small state if struck from cuttings.—T.

CAMELLIAS.

THAT fine new bright scarlet American variety *C. M. Hovey*, with its large and handsomely formed imbricated flowers, is one of the best for pot culture. It is handsome in growth, and also free-flowering. Those who saw the fine specimens in pots shown by Messrs. W. Paul and Son on the 5th of March will have realised its value.

The most striking of the red and crimson Camellias will be found in *C. M. Hovey*, *Madame Lebois*, *Beali*, *corallina*, *Andrea Doria*, and *Mathottiana*. Of pink and rose shades there are *Countess of Derby*; *L'Avenir*, a charming and very free variety; *Bella d'Ardiglione*, a finely formed flower with the inner petals a little paler than the outer ones; *Beauty of Hornsey*, a charming variety which sometimes comes with white lines on the petals; and *Marchioness of Exeter*. Those of a blush or delicate pink hue are *Comte de Hainault*, *Madame Ambrose Verschaffelt*, sometimes pink and sometimes white, with flakes or bands of pink, very fine; and *Eugène Massena*. Of pure white flowers there are *Montironi*, very fine, the petals remarkably stout and solid; *Princess Charlotte*, closely resembling the foregoing. *Cup of Beauty* is a variable variety that is sometimes pure white, sometimes tinted with flesh, and sometimes white streaked with rose, which is its true form, and then the white should preponderate; occasionally the rose is the principal colour, having on its stripes of white; *Countess of Orkney*, sometimes pure white, but should have stripes of carmine; *alba plena*, *imbricata alba*, *candidissima*, and *Mons. d'Offey*. The leading striped and flaked flowers are *Storeyi*, *l'Insubria*, *Bonomiana*, extra fine; *Archiduc Carle*, *Adelina Benvenuti*, and the fine old *Donckelaari* with its pleasing semi-double flowers.

The cause of dropping the buds in Camellias is no doubt mainly attributable to injudicious watering. I have known plants to fail where they had a little water given frequently which had only moistened the surface soil, while the main part of the ball remained quite dry. The simple rule to be observed with Camellias is not to water till a plant really requires it, and then thoroughly soak it. These plants are well grown in the Royal Nursery, Slough.

R. D.

Azalea mollis under glass.—Great numbers of this beautiful flowering shrub are now every year imported from the Continent, and find a ready sale in this country, which cannot be wondered at, as they lift with such close compact balls of soil that they do not at all suffer from the journey, and may then be potted up for flowering under glass, after which they can be hardened off, and are then available for planting out with other hardy shrubs. Besides the imported plants, great numbers are grown in this country for the same purpose, and many instead of being planted out are kept over year after year in pots, and flower well treated in this way, provided they are assisted with some stimulant during the growing season. When the blooms expand under glass they are thus rendered safe from late frosts, and also from the effects of very heavy rains, which often injure the expanded blossoms a good deal. This *Azalea* varies considerably in the colour of its blooms, but the range is not quite so great as in the other hardy *Azaleas*; the flowers, however, are more massive than in any of those kinds.—T.

Rubus rosæfolius coronarius.—Some four or five years ago this little double-flowered *Rubus* appeared likely to become very popular as a pot plant for winter blooming, but since then it has made little if any headway though its pretty white blossoms are by no means to be despised during the dull months of the year. It reaches a height of 1 foot or 2 feet, and when growing freely forms a rather dense specimen by reason of the numerous erect shoots that are pushed up from the base of the plant. If cuttings are struck now and grown on during the summer they form pretty little flowering plants by autumn,

when their blooms will be much appreciated. In the earlier part of the summer the plants must be encouraged to grow as freely as possible, by keeping them in an atmosphere favourable to quick growth, but by the end of July they may be hardened off and placed out of doors for a time. So treated, they will later on, when removed into a warmer structure, flower freely, and maintain a succession of flowers for a long time. Cuttings should be formed of the young shoots, which strike readily. This *Bramble* can also be increased by pieces of the roots. Red spider will need constant watching throughout the different stages of growth, as they increase very rapidly on this plant, and soon cause the leaves to turn yellow and drop.—H. P.

The Snowball tree (*Viburnum Opulus*).—Nearly everyone is familiar with this plant, which is largely planted in shrubbery borders, for the globular heads of snow-white flowers render it very conspicuous and attractive. It may not, however, be so well known that this is one of the very best plants for early forcing either in a small or large state, and is specially valuable from Christmas until February, either for the embellishment of the conservatory or dwelling-house, or for the production of cut bloom. This shrub is largely grown in this manner at Beddington House, Surrey, by Mr. Penfold, who describes it as one of the very easiest of subjects to manage.—G.

Azalea rosæflora.—This beautiful Japanese *Azalea* is now flowering profusely in Mr. Bull's nursery at Chelsea. The flowers are very double, made up hose-in-hose fashion; the petals are close, and form a beautifully imbricated double bloom, that when young resembles in shape the bud of a Tea Rose. The colour is a delicate salmon-pink, and so persistent are the blooms that they usually die upon the plant, unless picked off by hand. It would be interesting to learn the parentage of this plant, for although it was introduced from Japan by Messrs. Rollisson and Sons, of Tooting, it is not reasonable to suppose that it was found in a wild state; it probably having been brought about by cultivation in some of the Japanese nurseries. It is somewhat slow in growth, but is a most profuse bloomer, and is extremely useful for producing button-hole flowers, especially in the bud state. A coloured plate of it appeared in *THE GARDEN*, Vol. XVIII., p. 254.—G.

Monstera deliciosa.—This Aroid, which is a native of Mexico, and known also by the name of *Tornelia fragrans*, is tolerably well known as an ornamental-leaved stove plant, and is sometimes used with considerable effect in sheltered nooks in the open air during the summer months. It is remarkable for its large, leathery, deep green leaves, perforated with holes, and also for its long snake-like roots. It produces fruits about the length and shape of the Pine-apple. These when ripe are pinkish in colour and have a delicious flavour, quite distinct from any other fruit we know. In the gardens of Wimbledon House, the residence of Sir H. Peek, it grows vigorously upon a wall in the stove, and is at the present time bearing six large fruits.—G.

Bananas.—The fruits known by this name are mostly the produce of *Musa sapientum* and its varieties, which are very numerous. It is a tall-growing species, with stems that rise some 10 feet or 15 feet in height. These bear enormous bunches of fruits, which weigh from 40 lbs. to 60 lbs. or more. *M. chinensis*, however, which is perhaps better known by its garden name of *M. Cavendishi*, is a dwarfer plant, its stout stems seldom exceeding 5 feet or 6 feet in height, and produces large bunches of fruits in abundance. It is a plant that was more often seen in gardens some years back than it is at the present time, but it still receives considerable attention in Sir Henry Peek's garden at Wimbledon House, where several fine examples are at the present time ripening enormous bunches of fruits.—G.

Lachenalias at Beddington.—These old-fashioned Cape bulbous plants are far too seldom seen in our gardens, their spotted leaves and brilliantly coloured tubular flowers being extremely handsome. *L. pendula* and *L. tricolor* are two kinds which have for years been largely grown by Mr. Penfold at Beddington House, where he treats them as basket plants, and where they usually begin to dis-

play their beauty about Christmas. We observed on a recent visit that *L. pendula*, which is the largest-flowered and the showiest of the two, was just passing over, and that *L. tricolor* was ready to take its place. Treated in this manner, and by the use of open baskets, fine masses are obtained, as the shoots push out through the sides in all directions, while the spikes laden with tubular flowers stand at all sorts of angles, and have a very pleasing effect.

AMARYLLISES AT MESSRS. VEITCH'S.

THE display of these gorgeous spring flowers for the present season has, during the past month, been much better than usual. Owing to the late season it will be continued during the present month. To those who have closely watched the raising of these plants from seeds during the past ten years it is most interesting to note the progress towards perfect development of leaf and flower. A raiser of seedlings soon learns something of the initial difficulty in obtaining seeds from the best formed flowers, but it is only from such that real progress can be expected. The Messrs. Veitch have spared no expense in obtaining the best seedlings of other growers when it was thought the infusion of fresh pollen would be beneficial, or when a vigorous constitution could be infused into their own seedlings with well-formed flowers. The result has justified the means, and now there are to be found new colours such as have not hitherto been seen in the *Amaryllis* family, and with the new colours the flowers are also perfect in form, and as many as six of them on one scape. Form and size were obtained five or six years ago, and during the last two or three years the new colours have been developed. The greatest progress has been made in the light ground varieties, white or cream, flaked and marked with rose, red, or crimson lines. The parent of these fine light varieties was one of their own seedlings named *Lady of the Lake*. The most recent seedling from this is a variety named *Her Majesty*. The flowers of this measured 22 inches round the broadly opened corolla, the petals creamy white, slightly flaked with red. Hon. and Rev. J. T. Boscawen is also very fine, the flowers a mottled salmon, with a white band in the centre of each petal; *Marian*, white with scarlet feather; *Empress* has well-formed recurved petals, white ground, very pure light scarlet feathers; *Flowerdale*, creamy white, pale rosy red netting; *Atlantes*, white, neatly recurved petals lightly shaded with rose; *Norma*, white ground, feathered bright scarlet-crimson, creamy band.

To the above light-ground varieties must be added *Giantess*, a seedling from *The Giant*. It is quite distinct, has large and well-formed creamy white flowers, with greenish star and deep rosy red lines.

Great advance has also been made in the dark-coloured varieties, even the celebrated *Empress of India* having been left far behind. *Giganteum* is a remarkable variety, a seedling from *Tennyson*, but an improvement on that variety in form, size, and colour; the flowers measure 8 inches across, reddish scarlet. *Ensign*, scarlet, with a shade or suffusion of lake, fine form; *Lord of the Isles* is a distinct variety, rich in colour and of dwarf habit; *Amazon*, deep scarlet, pale green centre; *Rupert*, rich crimson with maroon tint, whitish star; *Hortense*, pale red, very handsome, broad white band in centre of each petal; *Eurasian*, dark crimson; *Endymion*, crimson, with cream coloured margin on each petal; *Antilles*, rose-tinted lake, conspicuous greenish star. *Purpurea* is quite a distinct type. The flowers resemble *Solandraflora*, and are of a distinct reddish purple on a whitish ground.

There are quite a thousand seedlings in flower, and the above are a selection of the very best; at the same time it is but fair to say that there are many more superior to the best-named older varieties now in cultivation. J. D.

Achimenes as basket plants.—Hanging baskets of mixed plants, flowering and foliage, are often a failure, through, as is too often the case, being inconveniently crowded or by blending to-

gether what may be termed incongruous subjects. Hanging baskets at flower shows are very frequently an unsatisfactory feature; they are planted for the occasion and then slung up in a hot tent without ventilation, with the result that in an hour or two they are not fit to be seen. I have a very lively recollection of the huge baskets of Achimenes I saw at Chatsworth a few years ago in the lifetime of the late Mr. Thomas Speed. They were very large, but with the branches hanging over and about in all directions, perfect masses of bloom. Moss, or some such material, lined the inside of the huge wire baskets, and then sufficient plants of one variety were put in to fill them. They soon established themselves, and when well in flower were objects of great beauty in the Victoria Regia house. The best varieties for the purpose are Ambrose Verschaffel, Baumanni hirsuta, Dazzle, Carl Wolfarth, Henry Williams, longiflora, longiflora major, Margaretta, Mauve Queen, and Mauve Perfection. R. D.

The Lace-leaf plant (*Ouvirandra fœnestralis*).—This vegetable wonder is peculiar to the island of Madagascar, from whence it was brought to this country by the late Mr. Ellis. Upon its first introduction it caused great excitement in the horticultural world, and realised high prices. Now, however, the novelty of its structure has passed away, and it has become comparatively rare, although by no means a difficult plant to manage. We were, therefore, recently agreeably surprised to find a fine specimen of this plant growing in an ordinary tank in one of the houses in Sir Trevor Lawrence garden.—G.

Lilium Harrisii. Whether this Lily differs from some of the varieties of *L. longiflorum* already in cultivation is a very open question, but at all events as seen in flower now it is very beautiful, and a useful subject at this season when white flowers are so much in demand. Great numbers of this Lily are imported every year from America, and also from the island of Bermuda, and though English-grown bulbs are to all appearances equal to imported ones, these latter can be induced to bloom earlier in the season, no doubt owing to the fact that they are ripened off sooner than they would be in this country. To have them in bloom now they should be obtained by September at the latest and at once potted in good open loam, enriched with well-decayed manure. Sand should be liberally used, especially around the bulbs. After potting they must be placed in a greenhouse temperature and kept slightly moist till the roots become active, when more water can be given, and directly the shoots appear the plants should be kept in as light a position as possible. So treated, the foliage will quickly become developed, and by the new year the plants may be placed in a structure maintained at about 55° by night, with a corresponding increase by day. In this way they will come on rapidly, and by about the middle of March the first flowers will expand, and at this season they remain in beauty a considerable time. One caution to be observed in the case of these Lilies when growing is to see that aphides do not effect a lodgment upon them, as in a few days they will injure the blooms to such an extent that they never open in a satisfactory manner. As they take shelter in the cluster of young succulent leaves at the top of the plant, they are not easily dislodged therefrom, except by fumigation.—H. P.

SHORT NOTES.—STOVE AND GREENHOUSE.

The Rose-flowered Butterwort (*F. inguicula rosea*).—This is a large-growing species forming quite a dense crown of its soft, bright green leaves. The flowers are borne upon long foot-stalks, and are large and flat, of a beautiful soft rosy purple colour. It is now flowering in Mr. Bull's nursery at Chelsea.—G.

Day Lilies in pots.—I have seen the beautiful yellow-flowered Day Lily (*L. flava*) grown in pots, and brought on in a gentle heat, so that by this time of the year it was in full flower. The blooms were remarkably attractive, for they were not only beautiful in themselves, but differed so widely from the majority of plants in flower at this season, and when grown in this way the perfume was most agreeable.—T.

Gas injuring plants.—Our plants get spoiled at intervals and do not flower. We can smell gas—which must be escaping from the main which is laid along outside the

walls—rising through the soil in the greenhouse. I would be obliged if any reader could inform me if this would injure the plants, or would the gas require to be burned before any injury would follow.—H. H. LANDMAN.

Begonias at Beddington House.—In the warm conservatory here numerous kinds of Begonias are planted out, and just now their spikes of bloom are both numerous and effective. The most noticeable are *B. Carrieri* with pink and white flowers; *B. insignis* (which is a large form of fuchsiodoid), vermilion-coloured trusses; and the old *B. manicata*, which has its leaf stalks curiously frilled with bright red. This produces large branching cymes laden with numerous delicate pink blooms.—G.

SEASONABLE WORK IN PLANT HOUSES.

STOVE TABERNÆMONTANA. The double-flowered variety of *Tabernæmontana* is amongst the most useful as well as beautiful stove plants in cultivation. The dense bushy form of a well-grown specimen, clothed with its glossy green foliage and thickly studded with pure white flowers, presents a very fine appearance. The twisted petals give a pleasing irregularity to the character of the flowers, that relieves them from the over-formality existent in many double flowers. The blossoms are deliciously fragrant, and are preferred by many to the favourite *Gardenia*, as the perfume is more delicate, and never elays in the way the flowers of *Gardenias* often do. For small arrangements of cut flowers, such as button-holes, sprays, bouquets, or wreaths, where white is required, the double *Tabernæmontana* is unsurpassed. Not the least of the merits attached to the plant is that it is easily grown, and gives a long succession of flowers. Like most other inhabitants of the stove, its time of blooming depends upon the amount of heat it receives. Plants that flowered last autumn and were cut back during the winter will now have made some progress, and if not already re-potted they should be shifted at once. It is not well to attempt to remove much of the old soil, except in the case of old specimens that have been partially headed down, as the disturbance of the roots would delay the time of flowering. Give pots a size larger, bearing in mind that this *Tabernæmontana* does not require so much root-room as some plants. In the case of specimens that are large enough they may be kept in the requisite condition by the help of manure water given frequently, with an occasional application of some concentrated manure. Plants in good condition will bloom two or three times before autumn. This *Tabernæmontana* strikes freely from cuttings made of the young shoots, which should be taken off when the wood is comparatively soft. Examples that were cut back about the beginning of the year, and have been kept in a genial growing temperature will now afford suitable cuttings, and where young stock is required no time should be lost in getting them struck, as the plants will then have time to attain strength before autumn. If the cuttings can be secured with a heel they will root quicker and with more certainty. They may be put, several together, in small pots filled with sand, and placed in a close atmosphere, with a brisk heat, and shaded, they will strike in a few weeks. When sufficiently rooted move them singly into 3-inch pots. The plant will grow in either loam or peat, but it succeeds best in peat, which should contain plenty of fibrous matter and have a moderate amount of sand added. During the growing season it enjoys a brisk heat. Keep the little plants well up to the light, giving a little shade in sunny weather. Stop the points as soon as top-growth is fairly in motion; this may require repeating a second time in the course of the summer, during which the plants will want pots 2 inches or 3 inches larger. Syringe freely in the afternoon at the time of shutting up the house. So treated nice thriving examples will be secured by autumn.

BORONIAS. The different species of *Boronia*, of which there is now a number of desirable kinds, including *B. pinnata*, still one of the best if not the very best—*B. elatior*, *B. Drummondii*, *B. megastigma*, and the new and beautiful species, *B. heterophylla*, are all deserving of especial notice by those who have a conservatory or greenhouse to keep gay with flowers through the late winter and spring months. Their natural disposition to bloom pro-

fusely, even whilst the plants are young, is such that small examples in 5-inch or 6-inch pots flower with the greatest freedom; their endurance is such, that in several of the kinds named they will last for six or eight weeks. In the case of *B. pinnata*, they keep on opening in succession, which, combined with the length of time they last, enables the plant to maintain a gay appearance for three or four months. Young plants should, after flowering, have their last summer's shoots shortened back to about one-third of their length, after which they must be potted. *Boronias* are freer rooters than most hard-wooded subjects, consequently, to do justice to them, they should not be stinted for pot room during the early stages of their existence. Plants that are now in 5-inch pots may be moved into others two sizes larger; the best fibrous peat should be given them, to which add a liberal amount of sand. It is important that the peat should be of a nature that will admit of its keeping in a suitable state for the roots to grow in it for a lengthened period, as the plants, with fair treatment, will live and maintain a healthy flowering condition for many years, and there must be no attempt at shaking the old material away. After potting, treat in the ordinary way that answers for hard-wooded greenhouse stock.

DAPHNE INDICA. The time of flowering these plants varies according to the treatment they receive in respect to warmth. Where wintered in an intermediate temperature they bloom so much earlier than if located in a cool greenhouse. Although, strictly speaking, these *Daphnes* do not require more heat than a cool-house affords, they still succeed better when kept in intermediate warmth, particularly whilst the plants are young, and after this during the time their annual growth is being made. Where the blooming is over the plants should at once be moved to where they will have the requisite warmth with a moist atmosphere. Where more root room is needed larger pots should be given, but those who have not had much to do with these plants will do well to be careful not to over-pot, as unless the plants are exceptionally strong and are kept warmer all the year round this is usually looked upon as necessary, large pots frequently cause their loss. Good fibrous peat answers best with some rotten manure and sand added. In this the roots make headway better than where loam is used.

DAPHNES PLANTED OUT.—I am no advocate for planting bushy-habited stove or greenhouse plants out in beds and borders to the extent that some now advise, on the score that they require less attention in watering and grow faster. Free-growing things, when turned out with their roots unrestricted, push ahead at a rate that often leads to the supposition that it is the right method, but after a time the plants get too large, and have either to be headed back or removed altogether to make room for young stock, either of which courses generally ends in a gap in the supply. To speak of turning *Daphnes* out in a border after giving a word of caution about their dislike to large pots looks like a contradiction; but there are some things that cannot bear much root-room when grown in pots that thrive freely if planted out, and the plants under notice are amongst the number. Where a place can be found for them on the wall of a low house or pit facing southwards, and where they will not be too far from the glass, they will grow at a rate that no amount of attention and skill can bring about under pot culture. Needless to say the bed must be well drained and made of good lasting material. The plants before being turned out should be in strong vigorous health, and have attained some size; small examples when planted out rarely do well. Care must also be taken to see that the soil is not over-watered, especially during winter when no growth is going on, and immediately after flowering when the energies of the plants are weak, and somewhat sluggish through the effects of blooming. The white variety *D. indica alba* requires similar treatment to the ruby tinted sort; its flowers are less showy, but the scent is more powerful, and on that account it is preferred by some.

CROWEAS.—Of the few hard-wooded greenhouse plants that bloom in autumn, these, when well managed, are amongst the most useful. Their flowers individually are less conspicuous than those of some plants, but what they lack in this respect is made up for the quantity produced and the unusual length of time the plants keep on blooming. These Croweas are very useful for standing about the side stages in conservatories and greenhouses, as being comparatively small growers they are suitable for a front position. To have them in flower early in autumn the plants should, if possible, be kept after blooming and during the spring in an intermediate temperature. Where they can be thus accommodated, and have manure water occasionally, the crop of flowers will be much more plentiful than when the growth is made in cool quarters.

ROCHEA FALCATA.—There are few things that have a brighter appearance in the conservatory or greenhouse in autumn than this pretty little succulent. A dozen plants interspersed amongst other things with their dense glowing scarlet heads of bloom studded with yellow anthers do much to enliven the whole at a time when flowers are not over-plentiful. The plant is easily increased from leaf cuttings; these will strike if put in at any time when the leaves are matured, but if the propagation is carried out early in spring, time will be saved, and the young stock will attain more strength. The leaves should be put in whole, inserting them about an inch deep and 2 inches apart round the sides of 6-inch pots filled with sand. Stand them in an intermediate temperature and give no water for several days, otherwise the leaves, from their soft, fleshy nature, will be likely to rot; for the same reason they must not be confined in a striking frame or under propagating glasses. A shelf where they will be close to the glass is the best place to put them. Give water in moderate quantity before the sand gets so dry as to cause the leaves to shrivel, but it is well to err on the right side by not applying too much or too soon until the roots are present, after which top growth will soon appear and then they may be watered more liberally. When an inch or two of growth has been made, put them singly with the old leaves attached into small pots well drained and filled with a mixture of loam and sand, or peat and sand. Keep them near the glass in a growing temperature during the summer. The plant is a native of the Cape, but is a little more impatient of cold than many that come from the same country; consequently, it is better kept during winter in a temperature of from 45° to 50°.

T. B.

BOOKS.

RECENT WORKS ON THE LARGER FUNGI.*

Now that the warm and showery weather of spring is swiftly approaching, many of the larger vernal fungi will appear in our pastures and

Agaricus (Amanita) vaginatus (quarter natural size).

hedge-sides and on our downs. The Morels are peculiar to the spring months, so is the delicious

* "British Fungi—Hymenomyces." By Rev. John Stevenson. Wm. Blackwell and Sons.
 "Text-Book of British Fungi." By W. Delisle Hay. Sonnenschein.

St. George's Agaric and many other fungi, both valuable and worthless.

Mr. Stevenson's two volumes treat of the Hymenomyces only, but this immense family

Agaricus (Leptota) procerus.

includes all the Mushroom-like fungi and all the Boleti, as well as many of the minor genera, which contain esculent species. In general terms Mr. Stevenson's volumes may be said to contain descriptions of all the larger British fungi, exclusive of the microscopic species; this, however, would not be strictly correct, as there is a considerable number of large species to be found amongst the Ascomycetes, a family not included in Mr. Stevenson's work.

We may say at once that Mr. Stevenson's two volumes are simply invaluable; the fulness and general accuracy of the descriptions, which are all brought up to date, are admirable. An enormous number of British species are here described for the first time in hand-book form; indeed, very few species indeed have ever been so fully described before in any work published in this country. Mr. Stevenson has founded

Agaricus (Volvaria) volvaceus (one-fifth natural size).

his work on the great masterpieces of the illustrious Swedish botanist, Elias Fries. There is a glossary of terms and a good index, with derivations of all the generic and specific names.

No student who works at the higher fungi can afford to be without these excellent and cheap volumes; with a moderate amount of care even the beginner should be able to correctly name the larger fungi from living examples. The labour in preparing the MS. and checking the numerous references must have been enormous, and all mycologists must feel under a debt of gratitude to the author. The work must have been entered upon as a pure labour of love, regardless of time or money recompense. The publishers have done their part as admirably as the author, for the volumes are first-rate examples of good paper and typography.

We have noticed a few slips and omissions amongst the derivations and the specific descriptions, but, taking the two volumes "all in all," we are not likely to see an improvement upon them for many years to come. Every genus and

sub-genus, 103 in number, is illustrated by a small wood engraving, by Mr. Worthington G. Smith, made either direct from Nature, or from that gentleman's water-colour drawings from Nature, now in the British Museum, South Kensington. Each illustration is drawn to scale, and shows a section, as well as the mere external appearance of the fungus. By the courtesy of the publishers we are enabled to reproduce six of the wood-engravings.

Mr. Delisle Hay's work belongs to a very different class from the above; why the book should be termed a "Text-Book of British Fungi" we cannot imagine, for the work only

Coprinus cornutus (quarter natural size).

discusses the so-called edible and poisonous species of the larger fungi. All the hundreds of botanical species of unknown quality are entirely omitted, and not a word is said about the enormous number of smaller species. The work contains a considerable amount of descriptive matter in reference to fungi in general, but we have observed so many errors in different parts of the work, that we have but little faith in any part. Even amongst the edible and poisonous species the slips are serious, although it must be acknowledged that the author appears to be familiar with the objects he describes. The work is published at such a low price that no doubt it will find purchasers, and these will find a good deal in the volume worth referring to—i.e., if the book be used with discretion and some previously acquired sound knowledge. It may then not be without its use.

The author has supplied "popular" names for all the fungi described. These names are

Nyctalis parasitica (half natural size).

atrociously ill-chosen and absurd, and ought to be mercilessly expunged in any future edition. If a few names are quoted our readers will appreciate their absurdity. We have, then, "Beelzebub's Cushion," "Bladder Elfcup," "Dark Jelly-sprout," "Guilty-sprout," "Infamous (Litocyebe)," "Sickener's Sister," "Pill-sprout," "Stinker," "Wrinkle-twig," &c. To make the case worse, the species are all *indeed* under these idiotic names. The result, of course, is that the index is perfectly useless, for no one

at present knows, or is ever likely to know or accept, this ridiculous and extensive series of so called "popular" names.

The book is advertised by the publishers as containing about a hundred plates and figures. Now, plates and figures are often the best part of fungus books, for whilst few persons can understand, or will care to attempt to understand the superfine jargon in vogue with some professional mycologists, yet everyone can understand a "plate and figure." Many persons buy books (especially foreign ones) for the plates alone, and no doubt many persons may be tempted to buy the work before us solely on account of the "100 plates and figures." Such persons will be bitterly disappointed to find that these plates are a mere hash-up of the little illustrations used sixteen years ago in Cooke's "Handbook." Most of the figures are illustrative of microscopic species, and not a word of description is given of such species in the book. Besides this, some are upside down, others only show a single spore, and one is a leaf-hair, and not a fungus at all. The "100 plates and figures" are perfectly valueless, for even if they had been described they would have

Lentinus cochleatus (quarter natural size).

been very little good, owing to the advances that have been made during the last sixteen years. Without description they are worse than nothing, for they spoil good paper and occupy space. We cannot understand this wholesale and unacknowledged use of the entire series of illustrations belonging to another author's book.

W. G. S.

ROSE GARDEN.

T. W. GIRDLESTONE.

GROUPING THE SPECIES OF ROSE.*

IN his most recent contribution to the literature of the Rose, M. Crépin, of the Botanic Garden at Brussels, has devoted himself to a minute analysis of the Systyle. The species which M. Crépin refers to this group are described in detail, particular attention being directed to various characteristics which, it is suggested, have been unduly neglected by botanists; such as, for instance, the form of the inflorescence which is made to constitute a basis for the division of the Systyle into two sections—those having an umbelliform and those having a pyramidal inflorescence; and a critical examination is made of the recent Japanese and Chinese forms out of which three new species are created. By the addition of these and the re-arrangement of others, the group is made so different from that of Mr. Baker, of Kew (as published not long since in the horticultural press), that it is worth while to compare the two side by side:—

GROUP I. (CRÉPIN) SYSTYLE.	GROUP II. (BAKER) SYSTYLE.
1. <i>R. microcarpa</i> (= <i>amyensis</i>)	
2. <i>R. multiflora</i> (= <i>polyantha</i>) (Sieb. and Zucc.), <i>intermedia</i> (Cart.), <i>thyrsoidea</i> (Leroy), <i>Wichurae</i> (Koch), <i>Calva</i> , <i>microphylla</i> , <i>trichogyne</i>	2. <i>R. repens</i> (= <i>arvensis</i>) <i>capitata</i>
3. <i>R. Luciae</i> , <i>Savaterii</i> , <i>firma</i> , <i>Luciae</i> , <i>adenophora</i> (?), <i>cratægina</i> , <i>yokosensis</i> (?), <i>genouina</i> , <i>hakonensis</i> , <i>platyphylla</i> (Hort. var. <i>Jap.</i>)	3. <i>R. sempervirens</i> <i>prostrata</i> , <i>scandens</i> , <i>Leschenaultiana</i> , <i>longicuspis</i>
4. <i>R. Wichuriana</i> , <i>fimbriata</i> , <i>poterifolia</i> , <i>adenophora</i> (?), <i>cratægocarpa</i> , <i>yokosensis</i> (?), <i>Maximowicziana</i>	4. <i>R. meschata</i> , <i>Dupontii</i> (= <i>nivea</i>), <i>Brunonis</i>
5. <i>R. tunquinensis</i>	5. <i>R. multiflora</i>
6. <i>R. anemone-flora</i>	6. <i>R. abyssinica</i> (= <i>Schimperiana</i>)
7. <i>R. setigera</i> (= <i>rubifolia</i>) <i>fenestrata</i>	7. <i>R. polyantha</i> (= <i>Luciae</i>)
8. <i>R. phœnicia</i> (= <i>chlorocarpa</i>)	8. <i>R. phœnicia</i>
9. <i>R. moschata</i> (= <i>Brunonis</i>), <i>abyssinica</i> , <i>Leschenaultiana</i> , <i>longicuspis</i> , <i>ruscinonensis</i> , <i>Pissarti</i> , <i>Godefroya</i>	9. <i>R. setigera</i> (= <i>rubifolia</i>)
10. <i>R. sempervirens</i> <i>prostrata</i>	10. <i>R. stylosa</i> (= <i>collina</i>) <i>leuco-livida</i> , <i>stylis</i>
11. <i>R. arvensis</i> (= <i>repens</i>)	

It will be seen that M. Crépin brings *R. microcarpa*, placed by Lindley under *Banksiana* and allowed to remain there by Mr. Baker, among Systyle, apparently on the ground of the extrusion of the styles beyond the disc in spite of their not being united, those of *Banksiana* being completely included, for although M. Crépin dwells on the fact that *R. microcarpa* has free stipules like *R. Banksia* (the stipules of all other Systyle being adnate), he expresses a very strong opinion that it cannot be classified elsewhere than among Systyle. It really seems as if it were the connecting link between the two groups, combining in itself some of the characteristics of both.

Second in the arrangement under notice comes the important species *R. multiflora*, near to which evidently are the various forms recently sent to Europe by Messrs Franchet, Takasima and others, and from which M. Crépin selects three as sufficiently distinct to be considered as separate species. A source of difficulty is probably present in dealing with these imported specimens of Roses, as of other plants from China and Japan, in the fact that so many forms have been from time immemorial in cultivation in those countries, that it is not by any means a simple matter in many instances to get at the true wild species, and some botanists would in all probability be inclined to class M. Crépin's three species *R. Luciae*, *R. Wichuriana*, and *R. tunquinensis* as sub-species or varieties of *R. multiflora*. But until more numerous examples and growing plants are compared, M. Crépin's opinion is entitled to especial consideration in view of the fact that he is by no means one of those botanists who are disposed to raise every slightly varying individual to the rank of species. Indeed, his remarks on botanists of this tendency, "who belong to the school of specific sub-divisions," and whose "hair-splittings (which, of course, may be repeated for every individual plant, and be made to furnish quasi-species into infinity) have yielded us hundreds, if not thousands, of species of *Rosa*," are much to the point, and contrast well with the sound rules laid down for obtaining evidence for the definition of true species, for which "it is necessary to take into account circumstances which may have an influence upon the form, the proportions, and the number of organs, to avoid losing sight of the action of dwarfing and its converse in growth, to bear in mind the inter dependence of various characteristics, not to forget the highly important fact of parallel variations, and lastly, to work upon sufficiently abundant materials collected as far as possible from all points of the area of distribution of the species." A botanist, therefore, working on such broad lines as are implied in the last para-

graph is not likely to constitute new species without good reason, and that M. Crépin is one of those who essay classification broadly under well marked types is further evidenced by the fact that he places *R. abyssinica*, which Mr. Baker allows to remain as a good species, as a variation of *R. moschata* in company with *Leschenaultiana* and *longicuspis* (sub-*sempervirens*, Baker) and *Brunonis*. On the other hand, *R. anemone-flora* (sub-*indica*, Baker) is elevated to the rank of species.

M. Crépin appears quite convinced that the original and true type of *R. multiflora* is the now well-known *R. polyantha*, often called in this country the Bramble Rose, from a certain resemblance of its flowers to those of the common Bramble. The arrangement of the prickles in pairs at the base of the leaves pointed out by Lindley as characteristic of *R. multiflora* is especially distinctive of *R. polyantha*; the fringed stipules also are very noticeable, and in other points, such as the pyramidal form of the very many-flowered inflorescence, the short round buds, the small corolla, and the leaves with nine leaflets, *R. polyantha* (Zucc. and Sieb.) agrees exactly with the description of *R. multiflora* (Thunb.).

Now that *R. polyantha* is so generally cultivated in Europe, it will be no easy matter to obtain general acceptance for the name *multiflora*, and in all probability the two names *polyantha* and *multiflora*, oddly enough identical in meaning, will have to continue side by side.

The point chiefly relied on for the differentiation of *R. Wichuriana* is the habit of growth of its shoots, which are procumbent, as with *R. arvensis*, but beyond this, *R. Wichuriana*, *R. Luciae*, and *R. tunquinensis*, all seem to have many characteristics in common with *R. multiflora*, the points of approach and divergence being easily comparable by means of the three very careful analytical tables which have been drawn up.

Some interesting remarks are made under the head of considerations of the relative value of species referred to the group Systyle, in which M. Crépin shows his consciousness (which, indeed, he makes no attempt anywhere to disguise) of the proximity of *R. Wichuriana*, *R. Luciae*, and *R. tunquinensis* to *R. multiflora*, by grouping, for the purposes of his discussion, the four together. He then goes on to point out that the more isolated types have a greater distinctive value than those that have several characteristics in common, the former representing the actual branches of the genealogical tree of the genus *Rosa*, the latter a secondary branching, probably due to evolution. But if this be so, the right of *R. Wichuriana*, *R. Luciae*, and *R. tunquinensis* to be considered good species will assuredly be questioned, for modern botanists are very loth to admit as species any form which can be directly traced to an earlier type. The suggestion that in the future fresh subdivisions may arise and be ultimately admitted as species, only renders it all the more imperative upon botanists now to avoid unnecessarily complicating the task of subsequent workers in the same field, and for this end to make it as clear as possible to what types already existing forms may be referred, or wherefrom they have originated.

Sweet Brier.—This can hardly be regarded as an attractive plant. It does not become conspicuous in size and its blossoms are very small compared with a good Rose, but for all that it is a sweet and pleasing old-fashioned subject that might be much more used in all gardens than it is. Plants of it in odd corners are sure to be found out by those who tire of the glare of Geraniums, and a hedge of it in the kitchen garden or pleasure grounds is far more charming than Privet or Laurel, the delicate fragrance of the Sweet Brier giving it a peculiar and uncommon charm. (CAMBRIAN.)

Rose Her Majesty.—The character which comes from America, that this Rose is much liable to be affected with mildew, is, I fear, but too well deserved. I had two plants of it as soon as they could be procured, and although they were grown for some time in a light, airy house, both plants

* "Rose Systyle." Par François Crépin. C. Annot-Bracekman, Ghent. 1887.

were severely attacked with mildew and no remedies that we applied had any effect. I then turned them out of doors and plunged the pots to their rims in a warm border. Still the disease spread on every newly made leaf. In the autumn I noticed that the disease had spread over the bark in large brown patches, as if it had eaten its way through to the woody stem. I fear this Rose is likely to be subject to this serious enemy of the Rose grower.—J. C. C.

TEA ROSES FOR FORCING.

THESE are the most valued flowers in our gardens during the early spring months, especially when in good health and free from greenfly, mildew, and other parasites. The buds and partly opened flowers are most beautiful cut with their foliage and placed in clear glass vases of small size. In gardens where no regular forcing-houses are available, or even ordinary greenhouses in which to grow the plants, it is not easy to make sure of a plentiful supply of blossoms, but the difficulties are not insurmountable. Pits or frame lights may be used to keep the plants in a growing condition. As the plants go out of bloom there is a tendency to neglect them, as they are often pushed into corners of vineries or other houses at a considerable distance from the glass, and where they scarcely receive any circulation of air. Instead of this, they should be placed in an airy place quite near the glass, and if they are stood in pits or frames, the lights might be removed altogether in fine weather. This is conducive to stout, healthy growth and leathery leaves of good substance. While being forced into growth in the spring, the flowers will not be first-rate unless the plants are placed near the roof-glass, where any air that it is necessary to admit can circulate amongst the leaves. Another error in culture is that of potting in a compost that is too heavy, and into which the roots do not enter freely. The turfy loam used in potting seems open enough at the time it is used, but after twelve months' watering it gets very close in texture, and many of the small rootlets die when they may inadvertently receive an over-supply of water. If a third part of good fibrous peat is used this may be avoided, and the plants are not so likely to suffer should it be necessary to place them outside where they may be exposed to drenching rains. Tea Roses ought not to be exposed in this way; it is much better to protect them with glass even during the summer and autumn months, abundant ventilation being provided. Many varieties of Tea Roses are furnished with flower-stems that are too weak to support the flowers in an upright position. A notable exception to this is furnished in a beautiful variety named Princess Beatrice, raised by Mr. Bennett, of Shepperton. It is a true Tea variety, raised by cross-breeding, and the stems bear the flowers erect, like a Hybrid Perpetual. A tray of blooms was exhibited at the spring exhibition of the Crystal Palace on March 26, and was much admired. The flowers are paler in colour, but more full than Madame Falcot, and are exquisitely perfumed. Madame Falcot is a free-growing, very useful old sort for cutting in the bud state; so also is the white variety Niphotos. Safrano is well known and greatly valued. A few other desirable varieties which have been well tried are Belle Lyonnaise, Madame Berard, Madame Eugène Verdier, Anna Ollivier (fine in the bud state), Catherine Mermet, Comtesse de Nadaillac, Hon. Edith Gifford, Madame Jules Margottin, Marie Van Hontte, Perle des Jardins, President, Souvenir d'un Ami, Sunset, and The Bride.

J. DOUGLAS.

Hybrid Teas.—The fulfilment of the hopes expressed by "J. C. C." on p. 275 was intended to have been effected in the notes on these Roses on p. 225, where a list being given of all the varieties of proved merit, it was left to be inferred that those not mentioned were of little value or attraction. There is little doubt that the less the names of worthless plants appear in print the better; many people will remember the name of a plant when they have forgotten any remarks that may have been

made about it, and though a flower may have been mentioned only to be condemned, it may yet under such circumstances be selected for planting because its name "has been seen somewhere." If, however, only varieties of merit are ever enumerated, the chance of their names becoming generally familiar is not then reduced by the frequent mention of worthless sorts which in turn are liable sooner to attain deserved oblivion. The varieties mentioned by "J. C. C." as well as many other hybrids of the same date have been carefully grown in considerable numbers since 1880, and all those not included in the list on page 225 have this year been finally discarded on account of some essential objection, such as lack of colour, constitution or attractiveness. Those discarded number nearly two dozen varieties, for which it has been found impossible to discover a use, either for exhibition, for supplying cut flowers, or as ornamental plants out of doors, and which consequently it is not worth anybody's while to grow. From Beauty of Stapleford it has not infrequently been found possible to obtain finely formed flowers for exhibition, but their production is not in any way worth the pains involved, as their dull colour always mars the brilliancy of a collection of cut blooms. Under these circumstances it is not obvious that any useful purpose would be served by the enumeration of these discarded Roses, especially as those growers that possess them can judge whether or not they are valuable to them, while those who have not got them will be less likely to obtain them if they are not reminded of so much as their names. The raiser of many of these discarded Roses has since given us such far finer and more beautiful sorts, that it is also hardly worth while to associate his name with varieties which, however useful they may have been as indications of the probable outcome of a definite experimental procedure, have not proved themselves of value to Rose growers in general.

KITCHEN GARDEN.

W. WILDSMITH.

MANURES FOR KITCHEN GARDEN.

AS regards the above, I have never had the good fortune to be in the enviable position of always having at hand abundant supplies of stable manure. I am satisfied that for every description of vegetable crop, stable manure stands unequalled; other descriptions of manures may, in some instances, prove equal to this for certain crops, but this suits all crops and soils alike. Then, in respect of its application, that the most nourishment may be extracted from it, there can be no doubt that the most certain mode of procedure is to bury it in a fresh state, a plan that we always adhere to when ground is being trenched, the decomposed supplies being reserved for ground that there may not be time to trench, but only to dig; so that long, strawy manure would not admit of cropping, drill drawing, &c., without some disturbance of the litter. Another way of applying the manure in this long state is as a mulching to such vegetable and fruit crops that in our judgment would be likely to benefit by the application. Peas, French Beans, and Scarlet Runners in the summer season are all thus treated, and that the crops may gain immediate benefit from it, a good watering is given as soon as it has been spread. All our wall fruit trees are thus treated, from 4 feet to 5 feet of border, next the wall, being at all times covered. In a decayed state this manure suits all vegetable crops, and for Lettuce, Radish, Coleworts, Cauliflowers, Turnips—in fact, any description of vegetable that readily absorbs whatever is put into the ground—it is specially well suited, as being mild in its action no taint is imparted to the produce, which taint is always present when sewage or other putrid manures are used. My indiscretion once led me to use in quantity on an Asparagus plot undiluted sewage from a cesspool that was

made to receive the refuse from kitchen, scullery, and stables. It was put on just as the Asparagus was breaking through the soil, and from the first few cuttings no complaint was made, but as the season advanced questions were asked as to what was the matter with the Asparagus, the taste was so bad. This was quite true. Since that occurrence we have been most careful in the use of any kind of manure, either liquid or solid, that owing to its strength would be likely to make the produce unpalatable. The sewage we still use, but in a greatly diluted state, and judging by its effects on both fruit and vegetables, the weaker form has the same stimulating effect on all crops as had the stronger dose, and there is none of the unpleasant astringency of taste in the vegetables. Another kind of manure that for lack of better we have to use is composed of garden refuse of every description—weeds, decayed vegetable matter, sweepings-up of walks, refuse soil, &c. This we collect in a heap, and once or twice during the winter it is turned over, soot and quicklime being intermixed with it as the turning over is being performed; these ingredients destroy all insects, and the lime neutralises any ill effects that, but from its presence, might arise from putridity. This we have tested as an excellent fertiliser for Potatoes planted on light soil. Wood and peat ashes, mixed with decayed leaf-soil, make an invaluable manure for short-lived crops, such as Lettuce, Turnips, Radish, and summer Spinach, and ensure a quick, succulent growth, and therefore mild-flavoured produce. As a manure for flower-beds, I question whether any other can touch it. For many years we used guano, but the quality at last so deteriorated, that crops that had no manure of any kind were just as good as those that had a dressing with guano. Bone-dust is too dear for kitchen gardening, although we use a limited quantity for fruit-growing with the best results.

LETTER FROM BURGHEY.

TO THE EDITOR OF THE GARDEN.

SIR,—We have just passed through a very cold month—14° to 17° of frost, with 6 inches of snow, and it has left its mark in my vegetable quarters. Lettuces, which I grow in quantity, are simply dead; Spinach, which I have never known to fail before, is killed. The borders are all dug and Ashtop Potatoes planted. Cabbage has stood better, and what a fine early Cabbage is that which is being sent out by Stuart & Mein, Kelso, N.B.; they are absolutely hearting. Nevertheless, after all these mishaps, I venture to predict March will be found to have been our very best friend. It has kept the fruit blossoms in their right places, with the exception of a few trees of very early Peaches, such as Amsden, Hale's Early, and Waterloo. The principal varieties are just bursting. Pears, Apples, Plums both on standards and dwarfs are studded with blossom buds. It will be perfectly well known that clear frosty nights are generally followed by fine sunny days. This has been the case all through March, and never have I seen a greater promise—Brussels Sprouts just making their appearance under glass, and fine La Grosse Sucrée Strawberries now ripe. All are satisfactory, so that should my prediction be right respecting a cold March, we shall all have much to be thankful for. My November-sown Peas are still looking fine. I am told that I do not preach what I practise; therefore I will try to do so, taking my text from the words "A cold March." My opinion is that a cold March is the best friend a gardener can have. I feel sure all your readers will agree with me when I say cold, frosty nights generally mean fine sunshiny days, and of all the helpmates we possess, the glorious sun stands a long way the first in all matters relative to forcing. I am indeed pleased to report that all my forcing houses give great promise; the same

may be said of flowers, vegetables, &c. It is said to be dangerous to prophesy "unless we know;" still I fully believe we shall reap a rich harvest of all kinds of outdoor fruit, which in a great measure we owe to a cold March. A noble lord and fruit land proprietor tells me that he always gets his rents better when we have a cold March. We also owe to the works of my text not only all these good things, but we have great opportunities of noting the hardiness of numbers of subjects under our charge; among them Strawberries may be noted. The great majority of our outside Strawberries are killed down to the ground line, but we see indications of growth in the hearts of the plants, though they look poor and puny. These varieties include President, Vicomtesse Héricart de Thury, La Grosse Sucrée, and Oxonian; but what a different look there is in those quarters planted with Pauline and Laxton's Earliest of All! The old leaves are fresh, green, and beautiful, thus showing they are not only improvements on existing varieties so far as the fruit goes, but are very much hardier. There is a great difference between these and the others mentioned, the former showing strong crowns and look vigorous, while the others, as I have said, are puny indeed. R. GILBERT.

Hardy Broccoli—Opinions differ greatly as to the hardiness of Broccoli and the ways of obtaining it. Mr. Gilbert's system of planting with the crowbar might do well enough in free, open soil, but on heavy, wet land I cannot see how it would succeed. It has been tried here, but with no success. We can grow good Broccoli on trenched ground. Out of a batch of 8000 plants I have only counted twenty vacancies; all the rest are looking well and not in the least damaged by the recent severe weather. The seed was sown the second week in April, and planted out the second week in June with the dibber on well-manured land. The varieties grown are Backhouse's Winter White, Veitch's Model, Knight's Protecting, Sander's Goschen, and Gordon's Niddrie. We are now using Backhouse's Winter White; the plants are not even laid in with the heads facing north.—OLIVOR.

The small-pot fallacy.—I am surprised to see Mr. Gilbert believing in small pots and mentioning Tomato plants nearly seven months old from cuttings just coming into bloom in support of it. I have seedlings sown in January as far advanced as his in 6-inch pots, and at least showing flower freely, and another 75 feet row of cutting plants struck later than his in big pots all about 3 feet high, with their first set well swelled and some nearly colouring. Yet I fancy I am behind. I do not believe in small pots in the sense advocated by some gardeners, nor does it appear to answer in Mr. Gilbert's case when he has to resort to stimulants; this would not be needed if his plants were not already starved. It will not do, this small-pot theory. Every plant needs a pot of a certain capacity to yield a maximum result in a given time. You may call the pot big or little, but that is the gist of it. There is such a thing as over-potting, but that is not what the small-pot advocates mean. The best crop of Tomatoes I ever had was from plants put out in a vinery border on the back wall, when the Vines were young in front and did not obstruct the light. These Tomatoes had abundance of root-room, were 12 feet high, and bore long and enormously such as I never saw before nor since. I am greatly surprised at Mr. Gilbert's winter Spinach being killed by frost; never knew such a thing in England or Scotland in the hardest winter. We have suffered bad enough from frost here this winter, and March has been the severest on record, but the Spinach is most luxuriant and abundant considering how little growth there has been.—J. S. W.

SHORT NOTES.—KITCHEN.

Dwarf French Bean Ne Plus Ultra—We are now gathering large quantities of this Bean; and after trying every sort that ever possessed the recommendation of being early, I have arrived at the conclusion that Ne Plus Ultra is the earliest and most prolific. It is very dwarf in growth, bearing heavily, and the pods are long, slender, and excellent in quality.—J. CURR, *Maryona*.

Early dwarf Peas for small gardens.—Tall-growing Peas should not find a place in small gardens. Probably the very best and earliest dwarf Pea in cultivation is William Hurst, a wrinkled variety with finer pods than those of American Wonder or Little Gem, and also more productive; while it rarely exceeds 1 foot in height. Then there is a great favourite of mine, Omega, a dwarf late Ne Plus Ultra, excellent alike in cropping and table quality, and not more than 2½ feet in height. A gentleman writing to me a few days ago speaks of these two as the Alpha and Omega of Peas. Here, then, is an early and a late variety that can be highly recommended. Sturdy can be grown for an intermediate crop; it is the same height as Omega, but perhaps scarcely so good, though that may be a matter of taste. But they are as useful in large gardens as in small ones, and by those requiring early Peas the variety William Hurst may be profitably grown. R. D.

KITCHEN GARDEN NOTES.

POTATO PLANTING. The fine weather has this week made us so busy in other departments of the garden, that this has been somewhat neglected; still, we have been able to plant a good breadth of the following varieties of Potatoes: Reading Hero, Abundance, Lapstone, and Schoolmaster. All the American varieties we long since discarded, as being much inferior in quality and very little more prolific, if any, to our best English-raised sorts. We give space, less or more, according to the height and spread of haulm of each sort. For strong growers we allow a yard between the rows, and the short-topped kinds from 2 feet to 2½ feet, and the same in respect of distance of sets in the rows, the dwarfed growers from 14 to 18 inches, and the stronger 2 feet. All are planted in drills and covered to a depth of from 4 inches to 5 inches.

PEAS.—Another good breadth of these has been sown on our very best land in shallow trenches to prevent the necessity of earthing up higher than the ordinary ground line. This sowing will be in a full bearing state in the height of summer; consequently any little item of culture that may conduce to the prolongation of the bearing state is worthy of consideration, hence the non-earthing up, that rain or artificial watering may have the fullest effect, which can hardly be the case if ridged up. The varieties now sown are several seedlings of the wrinkled marrow section, Ne Plus Ultra, Royal Jubilee, Telephone, and Satisfaction. By sowing several kinds at the same time there is greater reason to expect a longer succession, as no two varieties are ready for use at exactly the same date. It is not always practicable, but whenever we can arrange the cropping, so as to have the rows of Peas a long distance apart, we do it, and crop the immediate space with any quickly maturing crop, such as early Cauliflower, Lettuce, Spinach, and even early Potatoes. But whether such cropping be done or not, the rows should not be nearer together than 6 feet, as if crowded the pods seldom fill out, and there is great waste from the breaking down of the haulm when gathering the Peas. The earliest sown lot, if not already done, ought to be staked. We never defer this work, for if not done at time of sowing—which sometimes we do—the work is done the moment the Peas break through the soil, and thus they are protected from cold winds and destructive birds.

BROAD BEANS.—These we have thinned out to about 8 inches apart, and the ground being rather loose at their base from the action of frost, they have had a slight earthing up. The Spinach sown between the rows we found it necessary to dress with soot as an antidote against the attack of snails and grubs. Broad Beans are not valued very highly, so that they are only grown in limited quantity, and our last sowing has already been made, Broad Windsor being the variety. The cottagers in this district dibble in here and there a seed in their Potato quarters, so that their Bean crop takes up no ground, and being planted so thin, from 8 feet to 10 feet apart over the whole plot, it has no injurious effect on the Potatoes.

HOEING. After such a recent and lengthened season of snow-storms, it seems strange to be already at this kind of work, but it is a fact, nevertheless, and the soil works well. Purple-sprouting Broccoli, Curled Kale, and that hardiest of winter greens, Cottagers' Kale, are all having the ground stirred deeply between them to get as much and as quick a growth as possible, for the bulk of the Broccoli crops being a failure makes the demand on other green crops the greater. The ground occupied with autumn-sown Cabbage, which was previously cropped with Onions, not having been dug at time of planting, had got so hard that instead of hoes we thought it advisable to use forks to stir the soil to a depth of about 1 inches. We grow only the dwarfest varieties, and soiling up is, therefore, never required, as they are planted but a foot apart in the rows, so that weeds have but a poor chance.

VEGETABLES AND RIDGE CUCUMBERS.—It is time that these were sown. We raise both in heat and grow them on in pots, and if handlights or frames can be spared to place over the beds when the plants are first turned out, we press them into service till danger from frost is past, and the plants have started well into growth. Bottom-heat is not essential for either, but as regards Cucumbers, they start much more kindly if a little can be given. Marrows are more hardy and do not need it, nor are they fastidious in regard to soil. The beds that have been cleared of early Potatoes are first-rate positions for them, and as they are usually cleared of their crop by the middle of May, they come in just right for them, for without protection it is not wise to plant out earlier than that.

WORK IN PROSPECT.—Planting out remainder of Cauliflower plants that have wintered in frames; also Lettuce and Coleworts that have been raised in heat; pricking out Celery and a later sowing of Cauliflower; potting off seedling Globe Artichokes; planting Sea-kale; also preparing to sow both this and Asparagus, have engaged our attention. If showery we will give another slight dressing of salt or soot, or both, to Asparagus plots. None of our crops are so persistently attacked with slugs as these, and two or three such applications we are, therefore, obliged to give. W. W.

TREES AND SHRUBS.

W. GOLDRING.

THE FUCHSIA-FLOWERED CURRANT.

(RIBES SPECIOSUM.)

AMONG the earliest spring flowering shrubs this Californian Currant is one of the most beautiful and interesting, as it is so different from any other. It is aptly named the Fuchsia-flowered Currant, as its glittering red blossoms are more like those of a Fuchsia than those of any other Ribes. They are of similar shape, with long, protruding

The Fuchsia-flowered Currant (*Ribes speciosum*).

stamens, and hang on the branches in the same gracefully drooping way as a Fuchsia. It is altogether an elegant growing shrub, as its long shoots hang gracefully on all sides. Although

it is perfectly hardy in the southern parts of these islands, it is so beautiful that it is worthy of wall culture, and if the place is warm and the aspect of the wall is south or west the flowers appear as early as April, long before the open bushes flower. It, moreover, quite preserves its evergreen nature when against a wall, an advantage not to be overlooked. It likes a light, loamy soil, and no attention is required beyond that of encouraging new shoots by cutting away the old at pruning time. It thrives well along our south coast, and the finest plant of it I ever saw was growing in the Victoria Park, Bath. It was an isolated specimen on the lawn, and was 6 feet high and as much across, and covered with bloom.

HEDGES V. WALLS.

No one, I should imagine, would advocate the use of hedges in preference to walls for enclosing a garden. At the same time hedges are, in my opinion, of more value than some people suppose. They are not only useful for forming dividing lines, but they afford a great deal of shelter, and in many cases would have a more natural appearance. Those who have had much experience in growing kitchen garden crops on borders with a good aspect near to a well-furnished evergreen hedge must be aware of its capacity to afford shelter. The difference in the amount of shelter furnished by a wall is not much greater. However, that is my experience. There certainly is not the same power in the wind sweeping along a border next to a hedge as there is by the side of a wall. Perhaps someone will say a border next to a hedge cannot be so warm as one against a wall, but in practice there is not so much difference in the relative earliness of crops as might be supposed. It is proved in many cottage gardens all over the country. The vegetables are often as early as in those sheltered by high walls. At the same time I must not be understood as advocating hedges in preference to walls, and I acknowledge the fact that hedges harbour vermin, which is a serious drawback to their extended adoption.

There are several Evergreens suitable, but no doubt green Box makes the most compact and closest hedge. The large-leaved form of the common Box will form a hedge in much less time than is generally supposed if the leading shoots are not stopped until they get the desired height. There is no danger of the bottom getting thin if the sides are clipped once a year. If the plants are small when planted, it is best to put in a double line, allowing a distance of 1 foot between the lines and the same from plant to plant. The greatest objection to Box is its making so many roots; nothing will grow near it. This applies to all evergreen hedges, but with greater force to the Box. The only satisfactory way of getting over this objection is to make it a rule not to plant nearer to the hedge than 2 feet or 3 feet. Next to Box, the green-leaved Holly is undoubtedly the best to form hedges from 6 feet to 8 feet high. The common green form is the one generally used, but for the sake of variety and for securing a quicker growth I prefer the Minorea Holly, better known, perhaps, as balearica. This is a very distinct variety. For forming hedges or lines in any part of the dressed grounds, I think the variegated sorts are the most ornamental. If shelter only is the object which it is desirable to obtain with as little delay as possible, Lawson's Cypress (*Cupressus Lawsoniana*) is the plant to select; but, in my opinion, when this plant is clipped in the form of a hedge it is too stiff and formal to be pleasing.

Where there is sufficient space to allow the side growth to extend a little every year the Yew makes an imposing hedge, but it is hardly suitable in any position, except as a dividing line between the pleasure ground and the kitchen garden, because it impoverishes the ground so much for several feet on each side that nothing will grow near it. Hedges for boundary lines where cattle can reach them are best formed of White Thorn or Holly. The former is the most suitable, and where the land is fairly good and a double line of plants put in, a thoroughly impenetrable hedge may be formed in a few years

Not unfrequently Thorn hedges do not make the progress they would do owing to the indifferent preparation of the soil. In every case the ground should be dug up 18 inches deep over a space 3 feet wide, and then there will be no fear of the result. Unless the land is suitable for the growth of Holly I do not advise its use. J. C. C.

THE EUROPEAN BOX THORN.

(*LYCIUM EUROPEUM*.)

ALTHOUGH this thorny, rambling shrub is so commonly seen in cottage gardens, generally climbing over a porch or out-house roof, its

The European Box Thorn (*Lycium europæum*); branch with flowers and berries.

value in large gardens is not recognised. One often meets with steep, and exposed, and dry banks where ordinary plants or shrubs refuse to thrive, and if I am asked to name a few plants that will grow upon them I invariably include the Box Thorn, or Tea Plant, as it is more commonly called. For such a spot it is invaluable, as it is so indifferent as to soil, and

is no further trouble when once well planted, and, moreover, is an extremely rapid grower, for when established in good soil it makes annual shoots from 10 feet to 20 feet long, and if against a wall the shoots are even longer. It is highly ornamental from early summer, when it blooms, till autumn when it carries a profusion of small scarlet berries. Indeed, it is in flower and fruit at the same time, and the purple unripe berries, the purple and white blossoms, and the scarlet ripe berries on the same shoots have an extremely pretty appearance. On a bank the shoots spread out in all directions, and become in a short time so dense that the plant monopolises the space for several feet around it. It is a capital plant, too, for arbours and porches, as the shoots can be tied to pillars, and then allowed to spread in a canopy, dense enough to form a screen from the sun, and the flower and berry-laden shoots droop in a graceful way from the top. It is a cheap plant in nurseries, and the variety with yellow instead of scarlet berries may also be obtained. There are a few other so-called varieties of *Lycium*, but they do not differ much from the common European species; indeed, they are considered only varieties of a very widely distributed species. The names of these species are *L. barbarum*, *chinense ruthenicum*, and *ruthenicum*, but only the first-named is common in nurseries.

***Euonymus japonicus variegatus*.**—This *Euonymus* is a capital plant for covering walls, as when growing luxuriantly—as it does when planted in good soil and watered freely during hot, dry weather—its effect is charming. The variegation is more clearly defined, the foliage being larger, while the colour of the stems is bright golden. The leading branches should be laid carefully in close to the wall, while those shoots springing from the breast of the plant may be clipped in closely.—E. M.

***Araucaria imbricata*.**—This tree certainly forms a distinctive feature in the nursery of Mr. G. W. Piper, at Pittdown, Sussex. Some years ago two irregular lines of it were planted along the side of the nursery, running parallel with the main road; these have now developed into large trees, forming a beautiful avenue. The largest specimen is nearly 70 feet high, with a stem girthing 9½ feet, while its branches sweep the ground. We are told that the male and female catkins are produced on separate trees, but this fact is set at variance by what I saw here, both being produced on one tree, this circumstance, I was informed, being of annual occurrence. Moreover, Mr. Piper has raised a great quantity of seedlings from seed obtained from the trees in question.—A. HERRINGTON.

***Eucalypti in East Norfolk*.**—In July, 1883, I planted some trees of the Blue Gum (*Eucalyptus globulus*), the Mountain White or Cider Gum (*E. Gunnii*), the Spotted Gum (*E. gonicalyx*), in a corner that is sheltered from the north, and north-east, and north-west, and partially from the south-west (it had been an old sand pit), but exposed to the full force of the south and south-easterly winds; they have grown well and are fine trees; the *E. globulus* are 35 feet high, measuring round bole of trees 15½ inches 1 foot from the ground; *E. Gunnii*, 25 feet high, round bole 12½ inches; *E. gonicalyx*, 16½ feet high, round bole 9 inches. In the winter of 1883 I put some mulching of long manure from the stables about 1 foot up the boles, and they did not show any signs of being hurt by the frosts and winds until the following spring, when they looked a little browned for a short time. In 1884 I put a much heavier mulching on all, but more especially on the tallest of the *E. globulus*, which was then 22 feet high, to which I packed the mulching 2½ feet up the bole with the result that it died—I have no doubt from the dampness, being constantly close to the bark, so that it excluded all air. Since then I have only put a very light covering over the roots, which, so far, has been satisfactory. Just now they all (except one of the *E. globulus*)

look very much withered, but I hope they will start again after being cut back in May. E. Gunni has flowered here, but the flowers are insignificant. E. globulus has shown plenty of blossom-buds the last two seasons, but never has been able to open them. My object in writing this is to learn from other readers of THE GARDEN how their Gum trees have withstood the effects of the past three or four winters, and whether they have had any protection or not. South-east and south-west winds are very prevalent here in early spring and autumn, which is a great disadvantage to them, for their foliage is so heavy that now and again a branch will twist off.—J. E. SENDALL, *Brundall, Norwich.*

Acer Schwedleeri.—This hardy, free-growing, purple-leaved Maple should not be lost sight of by planters. It is a real acquisition, as far as effective contrast is concerned, amongst trees of light green foliage. Its leaves are of a bright reddish purple when newly unfolded, very brilliant and glossy, and as large as those of the common *A. platanoides*, or Norway Maple, of which it is a variety. W. G.

Privet hedges.—I am not in favour of introducing tender or very valuable plants as hedges in places where the main object is to secure shelter or shut out objectionable views, and, considered from all points, I know of no more satisfactory plants for hedges generally than Privet. The plants are very cheap, and if the evergreen and oval-leaved varieties are planted in mixed fashion they will form a fine hedge. They grow freely in every situation, and form a dense mass sufficient to obstruct cattle or break the current of wind; they bear cutting or clipping into any form, and when well trained are very ornamental.—J. MUIR.

Ampelopsis Veitchi This is a climbing plant that never requires the least attention bestowed upon it, as it will clothe even the smoothest wall with a dense covering of its beautiful foliage. It is, however, deciduous, thus losing its effectiveness during winter, though the gorgeous colouring of the decaying leaves in the autumn is some compensation for the bareness later on. The young growth attaches itself so firmly to the wall by means of the sucker-like points of the tendrils, that even if a large plant be removed, all that is necessary is to secure the principal branches in position, and as soon as growth recommences the young shoots attach themselves to the wall. I have moved several with great success, but find that the roots form very few fibres, so that in shifting them every root should be carefully preserved, and the plant attended to in the way of watering until established. H. P.

Undergrowth in pleasure grounds.—Those about to plant evergreen undergrowth under large trees in pleasure grounds should intermix, especially with Rhododendrons, the yellow Ghent Azalea. There are many colours of this fine, hardy, flowering shrub, but the yellow is the most robust, and makes the best rabbit-proof covert next to the Rhododendron. Being sweet-scented, moreover, gives it an advantage, and for coverts, in connection with dressed grounds, it is a decided gain. The yellow-flowered, black-berried *Berberis Aquifolium*, too, is a better rabbit-proof covert than the Laurel, which with us is more eaten by rabbits than any other Evergreen. Evergreens should never be planted in great sweeping masses, but should be divided and sub-divided by deciduous plants, and for this purpose the Ghent Azalea is well adapted.—W. G.

Zenobia speciosa.—This deciduous shrub grows about 3 feet or 4 feet in height, and bears pure white bell-shaped Lily of the Valley-like flowers in great profusion during the summer months. As often seen, however, it has a stunted and unhappy appearance, owing to being planted in too dry a situation. It is a native of swampy districts in North America; therefore it does best with us in damp, shaded parts of the American garden, conditions under which the *Clethras* and others of its more immediate allies succeed. A very distinct variety of this *Zenobia* is that called *Z. pulverulenta*, a plant covered all over with a white meal, and its flowers are larger and opener than those of the typical form. The *Zenobias* form pretty

objects for conservatory decoration when forced into flower in the spring; the pure white blossoms have a very chaste appearance, and the distinct hue of the variety *pulverulenta* shows up conspicuously amongst its green-leaved associates.—W. G.

The Red Maple (*Acer rubrum*) is a beautiful object in the landscape when it is unfolding its leaves in early spring. Its vermilion-red hue is sufficiently distinct to make it conspicuous. It has two distinct seasons when it assumes this striking colour—spring and autumn, but I think the tone of red is brighter in the autumn than early in the year. It is to be regretted that the Red Maple—for it is only in very old gardens that fine trees of it can be seen—is so scarce in the form of large trees.—W. G.

Rhodotypos kerrioides.—There is such a striking resemblance between this and the old Japanese *Kerria* (*K. japonica*), that it is difficult at first sight to distinguish the one from the other when not in flower. The *Rhodotypos* is a handsome shrub of slender growth, having opposite leaves with much wrinkled surfaces and large pure white flowers. It appears as yet to be very little known in cultivation, but it is a shrub that certainly deserves attention, as it is a beautiful object when in flower in summer. In a light warm soil in the neighbourhood of London it grows about 4 feet or 5 feet high and is perfectly hardy. It is a common garden shrub in Japan, but it does not appear to have been found in a wild state. Siebold, who first brought it into notice, believes it to be a native of the island of Kiusiu. W. G.

Varieties of Cupressus Lawsoniana.—Probably one reason that the variety of Lawson's Cypress known as *intertexta* is not so often met with as some of the others is the fact that it does not root from cuttings so easily as most of them; indeed, among the varieties of *Cupressus Lawsoniana* a very great difference exists in the readiness with which they can be struck. Generally speaking, the open, loose-growing varieties do not strike so readily as the more compact forms, and of these latter the easiest to root is the upright-growing *erecta viridis*, while *intertexta*, which is the most widely removed from it in habit, differs to the same extent in its rooting qualities. A good deal of the success or otherwise in striking cuttings will depend to a great extent on the conditions under which they have been grown, but where all are situated alike the peculiarities of each are rendered still the more manifest. The great difference between the varieties of one species in the matter of propagation is by no means limited to Lawson's Cypress, for many other examples could be quoted, though none perhaps to such an extent as in those mentioned above.—T.

PROPAGATING.

FOLIAGE BEGONIAS.—A stock of this class of Begonias can be easily obtained, as they grow readily from leaf cuttings, and quickly form effective little plants when increased in this way. Of course, division can be resorted to where large plants are at hand, and ordinary cuttings readily strike whenever obtainable, but the usual method, and the only one available for rapid increase, is to put in cuttings of the leaves. For this purpose, the leaves selected should be well matured, and at least 2 inches or 3 inches of the stalk must be allowed to remain on. This stalk is then inserted in the soil, leaving the leaf flat on the surface, when a few incisions made through the principal ribs will form a seat from whence the young plants are likely to spring. Pans or pots of soil may be used for laying the leaves on, or a little soil may be placed in the bottom of a propagating case, and the leaves dibbled therein without employing pots. This last method possesses the great advantage of economising space. Besides the stalk which is inserted in the soil, a few small pegs should be employed to hold each leaf in position, and to ensure its being in immediate contact with the soil. After a time young plants will make their appearance, generally at the base of the leaf, and where

the various incisions have been made. They may then soon be removed, and quickly make sturdy little plants. Where the loss of a plant or two is not so important a matter, a space that is often wasted may be utilised for the increase of these Begonias, but the same measure of success cannot be hoped for as when carefully attended to in a propagating house. I allude to a bed of Cocoa-nut refuse, or other plunging material in the stove, in which good-sized subjects are grown. A considerable amount of bare fibre is often seen, and on this the leaves may be placed in the manner recommended above. The overhanging plants will serve to keep the leaves shaded, and prevent them becoming shrivelled.

Another way of treating these Begonias is to cut the leaves up into strips and then dibble them in perpendicularly as cuttings, but this cannot be depended upon to the same extent as the other method. Save for the increase of any particular variety, Begonias of this section can be raised from seeds almost as readily as the tuberous-rooted kinds. By intercrossing about half a dozen distinct plants I obtained a large and varied assortment, most of which were equal to the named varieties. From the minute character of the seed it should be sown on the surface of the soil, and simply covered with a pane of glass till germination takes place. Then if pricked off carefully, the young plants grow away rapidly, but will need some time to fully develop their markings. From the appearance of my plants in their earlier stages, I fully expected to have a few distinct varieties amongst them, but as they increased in size these prominent markings disappeared and no new varieties resulted from this batch of seedlings. Other classes of Begonias are by no means difficult of increase, for those of the shrubby section can all be readily propagated by cuttings of the young shoots, which should be taken now, for especially in the case of the winter-blooming varieties this is the best time, as cuttings struck now and grown on throughout the summer will make good plants for flowering in the winter. The pretty and distinct *B. socotrana* admits of increase in rather a peculiar manner, for when in full growth small bulbils are formed at the base of the stem, which, when separated and placed under conditions favourable to growth, quickly root and form young plants. Those of the tuberous section that are now growing will yield cuttings if desired, the principal thing to guard against being to see that they are not kept too close and moist, otherwise from their succulent nature they are liable to damp off.

PINGUICULA CAUDATA.—Another instance of successful leaf-propagation is to be found in the case of this pretty Mexican Butterwort, which can be readily increased in this way, though on its first appearance in this country it by no means seemed like a plant that would be amenable to such treatment. To propagate this, the large leaves should be taken during the summer and stuck into pans filled with Sphagnum Moss, and a little sand sprinkled over. If the Moss be moist, the leaves will not require to be watered for some little time, and from their succulent nature they must not be put into close or moist quarters. A shelf in not too hot and dry a position suits them well, all that is necessary being to keep the Moss merely damp. In this way the old leaf will root, and push up a young growth from its base, and when large enough to handle they can be potted off, using for the purpose a compost largely composed of peat and Sphagnum Moss.

CROTONS, IXORAS, BOUGAINVILLEAS, FRANCISCEAS, and many other stove plants may now be readily increased from cuttings. As it is by no means difficult to strike the majority of the plants above mentioned, care should be exercised in the selection of the cuttings, which should be clean and well grown, as upon this the future of the plants will to a great extent depend. The cuttings should consist of good sturdy shoots of the current season which have become slightly woody in texture. Those with large leaves are best put singly in small pots, and secured to a stick to keep them steady. The soil for most things may consist of peat, loam, and sand, in equal parts, but for *Ixoras* the peat

and sand may with advantage predominate over the loam. If the cuttings of these different stove plants are plunged in a gentle heat, in a close propagating case, they quickly root, after which they should be hardened off, and without delay shifted into larger pots, as if checked in their earlier stages they will suffer later on.

LILACS.—Where these are forced into bloom they will be by now in full growth, and should it be desired to increase any, these young shoots may be taken off and struck in the same way as Fuchsias and similar subjects. Though such a method is scarcely likely to commend itself for the increase of the common Lilac, it may with advantage be employed for the propagation of the newer kinds, a great many of which have been put into commerce from the Continent within the last few years. In consequence of these new kinds being generally budded or grafted on the common Lilac, the suckers from the stock require constant attention. This is avoided by striking the cuttings, and where dwarf bushes are needed, this last is a very suitable means of increase.

EPIPHYLLUMS may now be readily grafted, and can safely be trusted in the hands of a beginner, for they are about the easiest of all plants to unite in this way. The stock mostly employed is the Pereskia, and all that is necessary is to cut the stock down to the required height, and having cleft it, insert therein the scion of Epiphyllum, which must have had its base fashioned wedge shape, in order to join well together. To keep all secure some cultivators pass a thorn or two of the Pereskia through both stock and scion, which is sufficient; the union, however, is not so neat as when they are tied with matting, which may be done without injury, for even should it cut through the wing-like part of the scion, no harm will result. After grafting, the plants should be kept close for a fortnight or so, but the case must not be too moist, neither should they be plunged in bottom heat.

GRAFTING is by no means absolutely necessary for the propagation of Epiphyllums, though from their drooping character of growth they are seen to the greatest advantage when elevated, and for this reason they are generally grafted. When grown in hanging baskets no grafting is needed, all that is necessary being to stick pieces of the Epiphyllum into the baskets wherever required, and when placed under favourable conditions they quickly strike root and establish themselves.

GARDENING BY THE SEA.

OUR climate along the southern coast of England is of such a favourable character that it offers a wide range for the cultivation of plants suitable for the open-air garden and as climbers against walls. There is a greater choice amongst climbers suitable for walls than any other, and to these I will first direct attention.

TECOMA JASMINOIDES. This plant is well known as a greenhouse climber, but it is not generally known that it thrives in a warm aspect on walls in the open air on the South Devon coast. At Dawlish, a mile inland, it thrives and flowers in the most satisfactory manner much better, in fact, than ever I saw it doing under glass, as the flowers are larger and produced in greater numbers, and the foliage is larger and of a darker shade.

BIGNONIA RADICANS. Although this creeper grows luxuriantly enough in many inland counties, one requires to see it in some of the gardens on our south-western coast to understand its capacity to produce a brilliant effect during the autumn months. No creeper with which I am acquainted is capable of covering so large a space in so short a time, or has such a singular and distinct character. It requires a rather rich and deep border for the roots to develop its qualities.

LIANTHUS PUNICEUS. In a suitable climate this is unquestionably the most brilliant creeper grown, as it will clothe a wall from 20 feet to 30 feet high with large bunches of its bright crimson flowers almost from top to bottom, and being an Evergreen further enhances its value. I am only surprised that it is not more grown

in the south and west than it is, for in a good soil after the first year of planting it will increase in height at the rate of 5 feet each year, and being naturally of a branching habit it fills up the wall without any pruning. Unless anyone has seen this plant draping the walls at Dunster Castle, with its gorgeous masses of brilliant flowers, it is hardly possible to conceive the striking effect it has, as it continues flowering for some time, the youngest wood being the last to flower. This Lianthus is not very particular about soil, for I have seen it thriving in a bed of lime rubble, and also in a loamy mixture. Cuttings of the half-ripe wood strike as freely as Pelargoniums in the early autumn, but they should not be planted out until the following spring.

STAUNTONIA LATIFOLIA.—This is another evergreen climber that is much harder than is commonly supposed; the growth and foliage render it a suitable subject as a climber; the flowers are of a dull brown colour, which make them somewhat unattractive. Its greatest merit is, I think, that the blossoms are highly fragrant.

PITTIOSPORUM TOBIRA.—This is another sweet-smelling Evergreen, suitable either for a wall of moderate height, or for growing in the form of a bush. The flowers are creamy white and are produced at the points of the shoots. It has rather a neat and stiff habit, and well furnished with growth down to the ground when the plant is not crowded by other subjects. There is also a variegated form, which is a counterpart of the other, except in the colour of the leaves, which have a creamy variegation. It will be found to make the best growth when a little peat is mixed with the soil.

BERBERIDOPSIS CORALLINA.—This plant also makes much more growth on open warm walls than it does under glass. It is not a striking plant even when in flower; the flowers are more remarkable perhaps for their singular form and colour than for their capacity to make an effective display.

FUCHSIAS.—As flowering plants for covering walls, or for growing into the form of huge bushes, there is nothing amongst what may be called half-hardy plants to equal them. Only in a few instances have their merits been recognised as suitable for the shrubbery border in a form large enough to render them conspicuous objects. I have seen a lower formed of hardy Fuchsias in a Devonshire garden, and in several instances they have reached to the tops of walls 10 feet and 12 feet high. Riccarton is, no doubt, the hardest of all Fuchsias for planting to form bushes, and the old corallina is the best for covering walls. For warm and sheltered corners, many of the better forms do exceedingly well even close down to the sea. I have seen the double-flowering varieties as well as the single flowered very beautiful in cottage gardens where only a low wall separated the garden from the sea.

BENTHAMIA FRAGIFERA.—This evergreen plant would certainly do well on warm walls all along the south coast, and it is quite hardy in sheltered shrubberies in some of the gardens in South Devon; as a wall plant its growth is of easy management. We have it growing on an east wall where it occasionally bears fruit, which are coral-red.

ROSE CLIMBING DEVONIENSIS.—Although this Rose may do fairly well in some inland gardens, I have never seen it doing half so well anywhere as on the sea-coast, where its growth is very remarkable, and the number of flowers far exceeding those produced on plants grown under glass. I can recommend this Rose for sea-side planting; of course it requires a good soil and plenty of room for its branches to extend, and only moderate pruning until it has filled up the space allotted to it.

MAGNOLIA GRANDIFLORA.—This is well grown in the form of standards at Sea View House, Dawlish. In this instance the plants were in the most satisfactory condition, many of the trees being nearly 40 feet in height with an ample spread of branches, which, when I saw them, were carrying many large flowers. The condition of these trees made it evident that they had not suffered in any way since they were planted; as a matter of course, they

were not fully exposed to the sea-storms of wind and rain, but were well sheltered by surrounding trees. I believe there are many sheltered gardens by the sea in which this Magnolia would do equally well as standards or bushes. Amongst other subjects which are suitable for the lawn or the shrubbery border I may mention *Choisya ternata*, which grows in the form of a low shrub with leathery shining foliage and sweet-smelling cream-coloured flowers.

OLEARIA HAASTI is of similar habit of growth, and suitable for planting either on the lawn or the shrubbery. It bears large heads of small white flowers. *Desfontainia spinosa*, sometimes called the flowering Holly, is also a useful Evergreen, suitable either for planting against a low wall or in a sheltered position in the shrubbery.

TEA-SCENTED ROSES. I am surprised that this very beautiful class of Roses has not been more grown round the coast. There are many gardens that can afford the requisite degree of shelter, and in these they may be grown with a degree of safety that is unknown to Rose growers in less favoured places. If the zonal Pelargonium will live for several years in open borders without injury, it is certain that Tea-scented Roses, being much more hardy, may be planted with safety. J. C. C.

Double Primroses. I see several correspondents in THE GARDEN have an idea that the double Primroses are descendants of *Primula vulgaris*. With one exception (called New Giant Yellow), I believe they sprang from *P. altaica*, a species flowering a month earlier than the typical forms of *P. vulgaris*, and certainly the parent of the best of our coloured Primroses. Pompadour is one of these, so I think is Double Sulphur, Ruby, &c. In Mr. Frettingham's nursery is a large collection, mostly *altaica* hybrids, and they come into flower any time in the winter during spells of mild weather, and in the spring they are masses of flower, more so than any selections I have seen of *P. vulgaris*.—WM. ELLIOTT.

We have received from Messrs. James Carter and Co., High Holborn, a pamphlet dealing very fully with the making and after-management of lawns, lawn tennis and cricket grounds, their formation and after-management.

From the director of the Royal Botanic Gardens, Kew, the April number of "Bulletin of Miscellaneous Information," containing notes on *Manilla Hemp*, which is obtained from the fibres of *Musa textilis*, the fruit of which is green and hard, and useless as food. Notes are also given on the fibre obtained from *Musa sapientum* and the Pine-apple.

WOODS & FORESTS.

"YORKSHIREMAN."

PINUS PATULA.

WE have little hesitation in saying, and most tree-lovers will agree with us, that as an ornamental Pine the above species is second to no other, and is well worthy of a far greater amount of attention than it has hitherto received. Once a tree or shrub, in fact any plant, is branded with the too-oft-bestowed title "half hardy," erroneous though it may be, it is hard to lift the veil and disabuse the public mind of the fallacy; and so to a great extent with the present tree—yes, and a dozen others that I could name. It is usually classed as a tender subject, only fitted for the mild climate of Southern England and the Channel Islands, and to be coddled in a shady nook and exposed to full sunshine.

This pretty Mexican Pine may not be so hardy as our Austrian and Corsican, but that it is by no means a tender subject may be inferred from the fact that from Edinburgh southward, throughout Ireland, and on the Isle of Man it does fairly well; indeed, in the latter place, wind-swept and cold though it be, it is, according to my friend, Mr. Farrant, healthy and well, and a much-cherished occupant of his well-arranged pinetum of choice subjects.

Pinus patula is, in truth, a lovely tree, and one that is quite wanting in the stiffness and formality that characterise the majority of its brethren, the long, lithe, and gracefully-irregular branches, draped with the finest and softest of foliage, being totally different to those of any other species that I can think of, and rendering the tree distinct and beautiful in the extreme. Usually the branches ramify to a great extent, in most British specimens the spread of these exceeding the tree's height; but, for all this, the stem never looks naked and bare, the long, soft, delicately green leaves hanging and swaying about with the least breath of wind, imparting to the tree, when viewed from a short distance, more the appearance of a mass of green velvet than anything else that I can recall to mind.

In most Pines the leaves are arranged in a certain order, but not so in the one in question, for although it is classed in most books and catalogues as ternate, or with three leaves in a sheath, yet I have nearly as often counted four as three; indeed, so as to arrive at some definite conclusion, I counted the number of each on a branch, and found that there were nearly as many threes as fours, but this I likewise noticed that invariably the four-leaved sheaths were arranged on the inner side of the branches, and those containing three on the outer. They are, in the specimen now before me, $7\frac{1}{2}$ inches long, remarkably fine and soft, and much recurved. The cones are arranged in whorls of about four, are fully 2 inches long by $1\frac{1}{4}$ inches in diameter, and either stand out at right angles to the stem, or are pointing downwards—usually the latter. As differing from most other members of the Pine family, the cones of this tree are produced on the stem at a distance of 2 inches or more from the previous shoot, and on stout, short footstalks. Before expanding, the buds are apt to attract attention owing to their long, narrow, sharp-pointed shape and fluffy appearance. Although *Pinus patula* cannot be ranked with the giants of its race, for it rarely, we are told, exceeds 60 feet or 70 feet in height, still it has proved itself to be a fairly rapid grower in this country, and soon forms a bole of 6 feet or 7 feet girth, and, in some instances, fully 40 feet in length, and well clothed from the ground upwards with plenty of branches and foliage. It is a tree above all others of its kind that wants plenty of room, and where this is allowed it, and a kindly soil provided with shelter from our worst winds, it grows rapidly after the first five years or so, or when it becomes quite established. Coddling it cannot abide, and even were it in its nature to do so, the loss sustained by the non-development of its long lower branches would be great indeed, for these are so cosy in appearance, and so well clothed with leaves, that half the charm of the tree would be wanting in their absence.

For planting in an open space and contiguous to

some of the more strict-growing members of its tribe this Pine is particularly well adapted, and in such a place—if on the greensward so much the better—its peculiarities are most readily recognised, and its fine, easy, sweeping character most appreciated. There are plenty of suitable positions for it in every park, but it is well before planting to study the tree's nature and under what conditions it has done best in England, for to unsuitable positions and soils may the death of several fine young trees be wholly attributed. Several of the southern counties of England can boast of possessing some of the largest and oldest trees of *Pinus patula*, but in other places as well and where climate cannot compare with these favoured spots it likewise feels quite at home, and puts on its best and most enticing garb. We are frequently told that it is difficult to procure, either "for love or money," young plants of this Pine, and this is perfectly true, for a perusal of a dozen of the catalogues of our biggest nurserymen reveals the fact that in not two of these does the name *Pinus patula* occur.

Home-grown seeds are scarce, if not, indeed, wanting entirely, for we have not yet seen male catkins on any specimens of this Pine, even on trees that have borne abundant crops of cones for many years. Now, however, that the tree has been found to be tolerably hardy in this country and of so ornamental an aspect, some plant dealer more enterprising than his neighbours will, no doubt, import seeds, and in a short time offer plants at a fairly moderate cost. It would be interesting to know how far north this Pine has been cultivated successfully, for I do not remember, save in Midlothian, of having seen any specimens or even young trees. Perhaps some reader will kindly let us know.

One of the finest and largest specimens we know of is growing at Pencarrow. It is upwards of 35 feet in height, with a girth at a yard up of $7\frac{1}{2}$ feet. Another, at Bieton, is of almost similar dimensions to the latter; while at Carelew, in Cornwall, there are several large and healthy specimens of 30 feet and upwards. The largest tree of this Pine at Balamoor, in the Isle of Man, is in good health and growing rapidly, its present height being fully 20 feet. In various other English counties it is likewise doing well, several specimens we know of being well-furnished, healthy-looking trees of from 15 feet to upwards of 35 feet in height, and with a spread of branches equalling, if not surpassing, in diameter the total height. On the Mexican hills at elevations of nearly 10,000 feet it occurs in considerable quantity, and was introduced to us by Lambert about half a century ago. A. D. WEBSTER.

Tree planting in Ireland.—It is admitted that fully one-half of the 4,000,000 acres of the waste land in Ireland is profitably reclaimable in the sense of [the capitalist or the speculator, but every acre of it is profitably reclaimable in the sense of the enduring prosperity of the country. The bleakest mountain-side, the worn-out bog, will produce timber, and an abundance of timber in Ireland would give it a new climate, new industries, and a higher civilisation.

Estate management. Will "Agent" kindly say what periodicals or books are best suited for study by one who is just about to undertake the management of a large estate?—J. W. L.

* * * "The Book of the Landed Estate," by Brown; Johnstone's "Agricultural Chemistry"; "Book of The Farm," by Stephens; "Book of Farm Implements and Machines," and "Book of Farm Buildings," by Stephens; Lindley's "Descriptive Botany and Vegetable Physiology," and Brown's "Forester," are all books every land agent should be possessed of and be familiar with. He should also see two or three of the best agricultural, horticultural, and other papers devoted to rural pursuits, such as *The Field*, *THE GARDEN*, *Farm and Home*, a good Scotch agricultural paper, and any others of the same class he can procure that are likely to meet his special wants. Books alone, however, will never fit a man for any post without practical application and keen observation at the same time, and in a land agent, practical knowledge on a great

variety of subjects is simply indispensable, otherwise he is almost certain to be frequently imposed upon by subordinates, dealers, contractors and others. Capable and trustworthy foremen in the different departments are a great help to an agent, but unless he has some experience himself he is no judge of such men, and it is not good for him to be dependent on their assistance. AGENT.

BARK AND BARK STRIPPING.

THE period of bark stripping and harvesting is one of the most anxious seasons of the year with the forester, as the quality of the bark is so largely dependent upon the weather during the time which intervenes between the stripping and the delivery, as well as upon the carrying out of the work at the proper time, to secure easy and expeditious peeling. In most cases, the time when the bud is just expanding into the leaf is that which gives the greatest weight of bark of the best quality, and with the smallest amount of labour. By deferring the work even for a few days there is often a loss in weight amounting to as much as 10 per cent., and a great deterioration in quality.

Even in the most favoured situations it is but seldom that the season for stripping extends beyond from twenty-five to twenty-eight days. In this district (Kent) it often reaches from about the 20th of April to the 20th of May in an early spring, and from about the first day of May to the end of the month in a late one. Much depends upon latitude and the exposure of the situation, and further north it is often from about the middle of May to the middle of June. The healthiest trees in the most sheltered situations break out earliest, and generally strip easily and yield good bark, while those of unkindly growth or in exposed situations linger in the bud, strip with difficulty, and yield bark deficient in tannin. Whenever hammering has to be resorted to, the cured bark is generally deficient in that bright inside creamy colour which denotes abundance of tannin matter. Such bark is also more liable to deteriorate upon the drying stage during the wet season.

Trees growing in sheltered hollows having a southern aspect yield the best bark. Under twenty years old the trees have not arrived at perfection for stripping, and after thirty years the yield both of tannin and other extractive matter diminishes. The astringent property upon which the value of the bark so much depends is most abundant in trees of middle age.

A calculation of the quantity of bark to be stripped may be made from the following data: A flourishing, well-proportioned, and full-grown tree will produce from 5 cwt. to 6 cwt. of bark for every ton of measurable timber it contains. Trees of medium age, averaging 10 feet each, will produce a ton of well-cured bark for every 150 feet of timber; hedgerow trees in favourable situations about a ton of bark to 3 tons of timber. The yield from plantations or coppice Oak will be proportionate to the space afforded to the growing timber. Where this is ample we may estimate a ton of bark for every 4 tons or $1\frac{1}{2}$ tons of timber. Small Oak poles will not average more than 1 ton of bark from 5 tons. All branches of 1 inch in diameter should be peeled, as these contain in proportion more tannin matter than the trunk bark.

The number of hands required to strip and stack a given quantity of bark in a stated time will depend upon the size of the timber as well as other circumstances. As a general rule, the larger the trees the fewer the hands. Taking the average of several years, I have found that about six or seven men, with two strong boys, will fell the trees and strip and stack 1 ton of bark in the day. The price paid per ton has for some years been £1 12s.

Before felling a tree, care should be taken to ascertain if both the body bark and that of the branches will run easily. An experienced eye will generally tell this at a glance. The necessary tools for felling and cutting up are the heavy and light axes and the handbill. For peeling the peeling-iron and the wooden mallet, made of Ash, about 4 inches square at the head and 7 inches long, with

a wooden handle. This will sometimes be found necessary for loosening refractory bark, but the less it is used the better the quality of the bark.

Various methods of stacking bark are adopted in different places. One of the most common consists in placing it upon a raised stage formed of strong forked sticks driven firmly into the ground, and upon which are placed longitudinally other peeled rods, so as to form a secure platform; upon this is placed the smaller shreds of bark, the whole being securely thatched or covered in with lengths of the body bark, averaging from 3 feet to 3 feet 6 inches. If the bark be well stacked, no turning will be necessary in an average season, when it is fit for delivery in about a fortnight; but should a long spell of wet weather follow, choose a fine day and open and re-arrange the stack. When the bark will snap between the fingers or under pressure and not bend, it may be considered fit for delivery.

During the process of curing, the inner side of the bark should never be exposed to the sun or rain. The stage should be raised sufficiently high to admit a free current of air under the bark; about 2 feet will be sufficient for this purpose. Bark generally loses about one-third of its weight in drying if properly harvested. A dull inside colour indicates bad curing or the presence of but little tannin. This matter, which gives the chief value to bark, is found mainly in the white cortical layers, which are situated next the albumen or sawwood of a tree.

In felling trees of an age to leave reproductive stools, great care should be taken not to strip off the bark down to the roots, as is often carelessly done, as this destroys the continuity of the dormant buds. While smaller poles may be advantageously cut down with the axe, all trees having a diameter above 6 inches to 8 inches are felled by the aid of the cross-cut saw; this will be found to be economy both of time and timber.

In delivering bark, it is customary to tie it up in bundles with withies for the convenience of loading. Formerly it was chopped in small pieces and afterwards delivered in bags. The cost of tying up is about 1s. 6d. per ton. Chopping costs 6s. or 7s. per ton.

As soon as the stripping and stacking are finished, no time should be lost in cutting up the cord-wood and fagots, and getting the whole of the produce removed from the fall. As the speedy curing of the bark depends so much upon the airiness of the situation in which it is staged, an open sunny and airy spot should be chosen, well removed from the shade and drip of trees. A. J. B.

Park and other roads.—After reading the very excellent remarks by "J. S." and A. F. Paterson on the above in THE GARDEN, pp. 292, 314, I think next to the importance of a good road is that of having it free from Moss and weeds, which I find is no easy matter, especially where the paths or roads are near to Grass which is allowed to seed. Last year I was induced to try Smith's weed-killer on the park roads here, as well as in the pleasure grounds and stable yard, and the result was that not a weed was to be seen all the summer, and even now, April 5, there is scarcely one visible. It not only destroys all vegetation, but gives a bright appearance to the roads, and I can with confidence recommend it. Care, of course, must be taken not to touch the Grass edges or the clothes of the user with the liquid. I have discarded salt in favour of the above, as I consider that after the strength is gone salt acts as a stimulant to the weeds. Another consideration is that it costs considerably less than salt.—ARTHUR LEE.

Spiders and trees.—Dr. C. Keller, of Zurich, claims that spiders perform an important part in the preservation of forests by defending the trees against the depredation of aphides and insects. He has examined a great many spiders, both in their viscera and by feeding them in captivity, and has found them to be voracious destroyers of these pests; and he believes that the spiders in a particular forest do more effective work of this kind than all the insect-eating birds that inhabit it. He has

verified his views by observations on coniferous trees, few broad-leaved trees, and Apple trees.

CARRIAGE DRIVES.

In the formation of carriage drives there are several points of importance that should be considered before the work is begun. In the first place, a graceful and easy line should be chosen, so as to bring into view as many features as possible. A circuitous route may in some cases be necessary on account of the undulation of the ground, but the case is altogether different when an indirect line is taken for the purpose of bringing into view some particular feature of the place. It is not advisable to convert a pleasing curve into a straight line for the sake of bringing any particular feature into view. The next point of importance is the width, and the consideration of this opens up others. These are the cost of the first formation and the after maintenance. I hold that to form a drive that will be pleasing from all points, the width must be in proportion to the extent of the surroundings. A narrow drive through wide stretches of open country has, to say the least, a poor appearance. A width of 16 feet is the least that should be allowed, and in many cases 18 feet or 20 feet would not be too much; whilst where space is limited less width may be given.

As regards the cost of construction, that will vary considerably according to locality and the kind of materials available. It is a general rule to use that which can be found in the district. This is right enough in its way, but may not be the most satisfactory in the end. As an instance, much of the red sandstone in some parts of the country is so soft, that it quickly grinds into mud in wet weather, and many of the flints obtained from pits are not much better. The cost of blue lias stone is prohibitive in many cases, but it is so superior to all others, that it proves quite as cheap in the end. If I had my choice of materials, I should prefer, for the foundation, a depth of about 5 inches of chalk and the same quantity of blue lias stone, broken into two sizes, the first layer being larger than the other, the top layer being about the size of a hen's egg, with just a sprinkling of fine gravel spread on the surface. This sort of stone has such an irregular surface when broken rather small, that it requires something to bind it into a firm bed, which when done no ordinary wear will disturb.

Drainage for the surface-water is a subject that will also have to be dealt with in a thorough manner, or the result will be subsequent vexation and trouble. Unless they are absolutely necessary, I have a great objection to underground drains, for if they are not regularly cleaned out they soon become useless. But if they must be used (and I am aware they are sometimes necessary) they should be large enough to take the maximum quantity of water. When it is possible, the surface-water should be led away by channels, and in the case of steep inclines there should be a space on each side about 18 inches wide, paved either with houlders or thiu, flat stones placed on edge. This space should be 3 inches lower in the middle than the outsides. To lead the water from these channels there should be outlets formed either with the same materials or wide, half-round pipes, which will prevent the washing away of the sides in cases of heavy rains. This brings us to the subject of the formation of the road. My conviction is that the form of the bottom when it is ready to receive the materials should be convex, and not concave, as some advocate. I am in favour of the convex form, not only because it is a saving of materials, but because it secures an equal distribution of the material; and whereas in the case of the concave form the bulk of the materials is in the middle, in the other there is the same depth where it is most wanted, *i.e.*, in the wheel-tracks. Solidity is a matter of the greatest consequence in the foundation of a road. It is, therefore, necessary to see that the form is correct, and that it is also made sufficiently firm, so that there will be no unequal depressions when the materials are all in their place. When the drive is made over unequal ground, it is a good plan to first get a rough level by filling up all depressions and levelling down any rising points, so that when laying the stones an equal quantity will be required over all the surface.

As to the depth of the materials, it should be in proportion to the amount of traffic likely to be upon it and the character of the ground. In a general way the depth should vary from 6 inches to 9 inches. If the road has to pass through damp and swampy places, the centre should be raised considerably, so as to admit of the surface-water running quickly away. The depth of the material should decide the size of the first layer. I believe there is nothing gained by using the material too large either at the top or bottom. There is more resistance and quite as much wear in a depth of 6 inches of stones put together in a compact mass as there is in a greater depth, where, owing to the large size of the stones, there are unoccupied spaces between them. With a thin layer of fine gravel scattered over the surface and a heavy roller to follow, a new road may be made both agreeable in appearance as well as easy to ride over. Repairing the road comes within the province of this article. I refer to it principally with the object of raising an objection against the common practice of doing the repairing in patches. I am aware that it is sometimes the case that roads and drives wear more in one place than another, and that judicious repairing is both useful and economical. I object to the practice of laying down narrow strips of fresh stones, which, in the majority of cases, are avoided by the drivers of vehicles, and roll about, to the manifest discomfort of both pedestrians and horses. The proper way to repair a drive is to break up the whole width of the road where faulty places exist, and after the surface is levelled to put on fresh material where it is wanted. When this is done the whole width will work down again to its original level, and as regards appearance and wear will be equal to a new-made road. J. C. C.

Tree roots choking drains.—A cure for this evil is coal tar. In using it, mix it with sawdust to the consistency of ordinary building mortar. A layer of this should be spread on the bottom of the drain; on this set the drain pipes, and then cover all over with the tar mortar. If the work be carefully performed, and the mortar applied in sufficient quantity—say 1½ inches thick all round—success may be guaranteed.

A curious geological phenomenon exists in the vicinity of Bebring's Strait. At Elephant Point, Kotzebue Sound, a ridge 2 miles wide and 250 feet high, seems to be a vast mass of ice, thinly covered with clay and vegetable mould. In this soil Birches, Alder, and berry-bearing plants grow luxuriantly, with the stratum of perpetual ice as the underlying rock within less than a foot from their roots.

Rabbits and trees.—During the late severe weather much damage has been done here by rabbits barking nearly everything before them. Many readers are misled by lists of trees and shrubs which, it is said, rabbits will not touch, but on this estate, I observe, nothing is safe from them, unless protected, except Rhododendrons. Sad havoc has been made amongst the common Laurel, with which many of the woods here were quite thickly planted some time ago; they are now in a pitiable condition and gradually getting thinner. The Portugal Laurel has also suffered, but not to such an extent as the common one. I also observe loppings of trees in the coverts entirely cleared of bark. Larch, which they even bark in summer, rabbits appear to have a great liking for. All kinds of forest trees are liable to be attacked when first planted; therefore it is better to plant one hundred trees and carefully protect them, than plant five hundred to be mutilated, and take their chance of surviving in a deformed and stunted condition. Newly formed plantations should be protected by placing wire-netting not less than 3 feet high around them. It should be fixed to upright posts, and in pegging down, 3 inches at the bottom should be turned out and laid flat on the ground, taking care to have it well fastened down. Where we cannot use wire-netting we place pieces of stick, dipped in tar, against the trees, which practice serves to protect them a little.—OLITOR.

No. 804. SATURDAY, April 16, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

STOVE AND GREENHOUSE.

T. BAINES,

EPACRISES.

EPACRISES when well grown flower almost from end to end of the preceding season's shoots, forming densely clothed sprays of elegant blossoms, that not only last long when allowed to remain on the plants, but also stand well when cut. When the plants are in rude health their long, profusely flowered shoots have an elegant appearance associated with other flowers of more formal character. To those who have to provide a continuous supply of cut bloom there are few things so reliable, as when properly treated they never fail to flower. The extent to which the flowers of most plants may be cut is limited, as in some cases, if too much of the growth is cut away in gathering them, the plants suffer in future. Not so with Epacris. To keep them in shape, it is necessary each spring, before growth commences, to shorten all the preceding summer's shoots by removing two-thirds of their entire length.

Epacris are more easily grown than most hard-wooded plants, proof of which is seen in the large healthy old examples that are met with in the hands of cultivators who attend fairly to the wants and particular requirements of the plants they grow. They are moderately free rooters, but do not like too much pot-room. A careful and judicious use of the water-pot is one of the essentials to success in their cultivation. In common with most plants indigenous to the same countries—New South Wales and New Holland—they require the amount of moisture to be regulated by the more or less active condition of both root and top growth. When in gathering the flowers the plants have been to a great extent denuded of the preceding season's shoots, or after the blooming they have been shortened back previous to growth commencing in spring, the soil should be kept much drier than in the summer, when the tops and also the roots are in an active state.

Though Epacris do not require more warmth than an ordinary greenhouse affords, still, if the plants after being cut in can be kept slightly warmer, it will accelerate growth, and assist them in getting over the weakening effects of flowering and of cutting in. Plants that began to bloom in autumn, and that after flowering had their shoots shortened back in the way described, will, if they require more root-room, now be in right condition for potting, having had sufficient time to enable them to break freely. Good fibrous peat, neither too light nor too heavy in texture, with a liberal addition of sand, is the best material in which to grow them. In potting use the lath freely, so as to make the soil quite solid. Where light potting is adopted the soil holds water like a sponge, a condition that will not answer for any plant that does not like its roots being in contact with saturated material. After potting keep the atmosphere a little closer than ordinary by giving less air. Shade when the weather is bright; the material used must be thin, such as will break the sun's rays without darkening the plants. After the roots have begun to move in

the new soil no shade will be required, except in the case of small plants that necessarily are in little pots.

Epacris are such free flowerers, that they will bloom whilst quite small; when they are large enough to occupy 6-inch pots and have made a season's growth in these they will yield an acceptable amount of flowers for cutting, or where required the plants will be equally useful for the greenhouse. To admit of their producing the full quantity of bloom they are able to, it is necessary that they should have their shoots thoroughly ripened. This is best effected by standing them out of doors where they will be fully exposed to the sun, allowing them to remain out until there is danger from frosty nights or drenching autumn rains. There is a considerable difference in the time that some varieties flower as compared with others. The autumn and early winter bloomers are mostly erect in their habit of growth; in these the plants do not attain so large a size as the late-flowering, more robust, drooping growers, which are represented by such kinds as *E. grandiflora rubra*, *E. miniata splendens*, *E. Eclipse*, and others of like character. These last are best for blooming in spring, from April to the end of May or later, but if required late the blooming must be retarded by keeping the plants through the spring in a north house where little sun can reach them. The time of flowering in Epacris can be regulated by the time the plants are turned out of doors in summer, as immediately they are exposed the flower-buds begin to form; this occurs whether shoot extension is completed or not. Consequently where a long succession of flowers is required, all that is necessary is to have a sufficient number of plants, and to turn them out in batches at different times. Plants that are forward enough in their growth may be stood out about the middle of July. This refers to the earlier blooming section already described; the strong growers flowering in the spring must be put out at the same time as the second set of early bloomers, about three weeks later. During the first few days of exposure it is well to place the plants where they will not be under the full influence of the sun in the middle of the day, as it sometimes browns the leaves. In the case of small examples they should be stood as near together when out of doors as they will bear without overcrowding; by these means the sun's rays will be prevented from reaching the sides of the pots. It is necessary to guard against this with all hard-wooded plants when in the open air in summer. With both large and small examples means must be taken to prevent worms getting into the pots. A bed of fine coal ashes 5 inches or 6 inches thick on which to stand the plants is the best preventive.

Each season the plants should have their shoots shortened back in the manner already spoken of; this ought to be done immediately the blooming is over, as then they begin to make growth more or less according to the time of the year, and when this is allowed to go on and the cutting back is effected afterwards it is so much of the energies of the plants wasted. Treated as advised, Epacris will keep in a healthy flowering condition for a very long time. I have had plants as strong and full of vigour when a dozen or fifteen years old as they ever were.

One of the advantages connected with the cultivation of these plants is that they are rarely attacked by insects, unless they are stood so that their shoots are in contact with some other plant on which scale exists. If affected with

the brown species it can be easily killed by washing and dipping in insecticide; this should be done when the plants are cut back after flowering. White scale is more difficult to deal with, yet can be destroyed by repeated applications of insecticide.

MIGNONETTE CULTURE IN POTS.

By growing in pots this may be had in flower from the beginning of December until the end of April, and the wonder is that it is not more cultivated in this way. To have it in perfection during the period named two sets of plants are required, one set to be grown on what I will term the bush method, and the other set as standards. These latter plants are most useful for the decoration of the conservatory during February, March, and April. By this method the best spikes of bloom are produced; we have had several measuring from 12 inches to 15 inches in length, the variety being Miles' Spiral. Its habit of growth is robust, while the flower-spikes are strong, erect, and the flowers very sweet, while the individual blossoms are large. Another good variety is Golden Queen, which has a somewhat yellow appearance; it is very sweet and of good habit of growth. To have the plants in perfection at the time stated, the seed should be sown about the middle of May, as if later, the plants do not get sufficiently strong to ensure the best results. Some growers affirm that Mignonette does not transplant successfully from the seed-pot, but this is a mistake, as no harm need be apprehended if ordinary care is taken with the seedlings. The best way to ensure good results is to sow the seed in small pots, three or four seeds in each, using half loam and leaf-soil, with a liberal sprinkling of coarse silver sand. The best position at this time is a cold frame placed under a north wall, where the seeds quickly germinate; when the plants are well through the soil give air freely, to induce a stocky habit, which is essential to their future success. As soon as the plants can be handled, remove all but one from each pot. If a sufficient number of pots was not previously prepared, the seedlings taken from the others may be potted into small pots and kept close for a few days. When the pots are nicely filled with roots and before the plants become pot-bound, they should be transferred into 3½-inch pots, using the same sort of soil in which the seed was sown. When the plants are 3 inches high it must be determined for what purpose they are intended—bush-plants or standards. Twelve to twenty plants of the latter are usually sufficient for most large places. For standards select the strongest-looking plants; to these place a thin stake, securing the plant before it becomes bent, remove all side branches as fast as they appear until the desired height is obtained, which should not be less than 2 feet; pot into larger pots as required; the final one may be 9 inches in diameter. The soil at the last potting should be composed of two parts fibry loam, one part horse manure, half-part of leaf-soil, with a good sprinkling of finely-ground bones; add some charcoal, which serves to keep the whole porous and sweet.

The final shift will not be required until the plants are housed the first week in October. After the plants are well established in the first pots from the seedling, the position should be changed from behind the north wall to one where more light can be had, shading the plants in the middle of the day. The plants should be well syringed every evening in warm weather; air also should be given during the night. Those plants intended for "bush" growth should have their points taken out when 3 inches high, to induce the formation of side shoots; these in turn should be pinched when 3 inches long. At this stage stakes will be required to support the branches. Some of the plants may be stopped until the end of September; whilst, to prolong the supply of bloom, the stopping may be continued with the remainder for a month later. Pot as required into various sized pots; for the largest plants 10-inch ones should be used, using the same kind of soil as for the standards. Great care should be exercised in supplying the roots well

with water, as neglect of this soon causes the leaves to turn yellow. Red spider quickly infests them. Inattention to these two matters soon renders the plants unsightly. Syringe the plants freely every evening during hot weather. During the first week in October the plants should be housed in a light, airy greenhouse or other structure where they will receive plenty of air. They must be placed near to the glass to prevent the shoots becoming drawn up weakly. If at this period a night temperature of not less than 45°, with a rise of 10° by day, can be given, they will receive much benefit. Some of the plants should be once more stopped, and these will continue the supply of flowers until the beginning of March, or even later, when the standards will come into bloom. The bush plants will have abundance of roots at the time they are showing their blooms, and will require to be freely watered, using weak liquid manure at each alternate application. At the same time the branches must be tied out to prevent crowding. Trellises, of about 2 feet diameter and 1 foot high, upon which to train the shoots of the standards are often used; these should be made of galvanised wire, and supported by a stout stake placed in the centre of the pot, the trellis being securely fixed to the top of the stake to keep it in position. This should be done as soon as the final potting has been accomplished. It is very difficult to fix the trellis after many branches are formed without causing damage to many of the shoots. After the main branches have been tied to the trellis, the points of succeeding shoots must be pinched out as fast as an inch or two of new growth is made, otherwise bloom-shoots will take the lead before the trellis is nearly covered with branches. The growths should be tied down to the trellis even after the flower-spikes are visible. If tied down too soon, the spikes by their weight bend the slender stems. When the flower-spikes are 6 inches long, and sooner in some cases, the seed-pods will form at the base of the stem. If these are removed, the flowering period is much lengthened. E. M.

Tropical Sundews (*Droseras*).—Although these plants cannot be esteemed showy, they are nevertheless very curious. The common British species (*D. rotundifolia*) is a delightful and familiar plant, but its beauties are far surpassed by its tropical allies. We recently observed strong masses of the fine *D. capensis* in Sir Trevor Lawrence's garden. It has stalked oblong-obovate leaves, the whole surface densely covered with red viscid leaves. It rises with age upon a somewhat stout red stem, and sends up a scape bearing medium-sized red flowers. It comes from South Africa. Two species, viz., *D. capensis* and *D. binata*, are also just now in fine condition in Mr. James's nursery at Norwood, growing in company with the cool Orchids. In the latter plant the leaves are borne upon long, erect footstalks, the leaves several times dichotomously divided, the divisions being long and narrow, profusely clothed with red viscid hairs, the scape bearing white flowers. It is a native of Australia. Upon a recent visit to Kew Gardens we observed good examples of the kinds previously named, and in addition *D. spatulata* and *D. auriculata*; the former may be described as a smaller and more caespitose form of *D. capensis*, and is indeed considered as identical by some authors. It is a native of Australia. *D. auriculata* is a distinct and elegant species, and one which we have not observed in any other collection. It rises upon a slender, erect stem, some 6 inches or 9 inches high, bearing alternate ear-shaped or lance leaves on its entire length, these being clothed with delicate pinkish red viscid hairs, and the terminal scape bears rosy pink flowers. It is probably from India. —G.

Clianthus puniceus.—As a greenhouse climber, or rather as a suitable subject for covering a portion of roof or the end of a glass structure, this *Clianthus* is one of the finest plants we possess, yet it is by no means common, and that not from any difficulty in its culture, as it will, if attended to in one or two particulars, grow very freely and soon cover a considerable space. Plants raised from cuttings are the best, for not only do they flower more freely, but the cuttings can be taken from a specimen with the finest flowers whereas

there is a certain amount of variation in the colour of seedlings. The cuttings should be taken at this season, or a little later, according to the position of the parent plant. The young growing shoots must be selected for the purpose, and the weak or medium ones are much preferable to those that are stronger. Each cutting should be about 4 in. or 5 in. long, only the bottom leaves being removed for the purpose of insertion. Pots 4 inches in diameter, well drained and filled with light sandy soil, are suitable for the insertion of the cuttings. From four to six cuttings may be put around the edge of each pot, and they must then be kept in a close case and shaded from the sun till rooted. In about six weeks they will have formed roots, when air must be given, and as soon as sufficiently established the young plants should be potted. An open turfy loam with a fair admixture of peat and silver sand suits this *Clianthus*, and as the plants get larger less of these two last materials will be needed. Where intended for covering a considerable space, this *Clianthus* should be planted out, but it will be necessary to thoroughly drain the bed before planting, as though a liberal supply of water is beneficial when in full growth, yet stagnant moisture is very injurious at all times. Should the atmosphere of the house be dry, the *Clianthus* is very liable to the attacks of red spider, which must be guarded against by a liberal use of the syringe. For this reason the cuttings should be closely examined before insertion, as a few insects will in a close case rapidly spread, and greatly disfigure the foliage. Though a dry atmosphere is favourable to insect pests, too much moisture during winter will tend to encourage mildew on the foliage.—H. P.

CALADIUMS.

WHEREVER there is a warm pit, intermediate house or stove, *Caladiums* should be grown in quantity, as they are amongst the most ornamental of all foliage plants from May until November. The markings of the leaves are very striking, and the general effect of the plants when well developed is exceedingly pleasing. Many choice stove plants could be named that are difficult to keep in good health in ordinary stoves during the winter. *Caladiums*, however, are quite different, as their bulbous roots can be stored away in a room during the winter, and they need not be started until the season is far enough advanced to assist their growth. Unless forcing appliances are very good no attempt need be made to begin their culture until early in April, as their growth in February and March is never satisfactory, and bulbs placed in a moderate heat now will be in full leaf by June. The best way to treat *Caladium* bulbs in winter is to keep them absolutely dry, and in a temperature of 60° or 65°. We always turn ours out of the pots when they die down in autumn, and store them in a box in dry sand, and from November until March they occupy very little space. In starting them we take them from their winter quarters and pot them into a mixture of loam, leaf soil, and sand. Large bulbs are placed singly in 5-inch or 6-inch pots, and smaller ones are grouped in threes, fours, or fives in the same sized pots. The pots are carefully drained, and the bulbs covered with the soil. They are then placed in a temperature of 65° or 70° where the atmosphere is moist, but they are not plunged or watered much until the young growths are observed pushing through the soil. If they can then be placed in a bottom heat of 80° and watered freely the foliage will develop rapidly. The object of placing the bulbs in small pots at first is that they may be more easily repotted into larger ones without disturbing the roots when they require more root room, and when the foliage has gained a good size and the pots are full of roots they may be potted on into larger pots without receiving a check, which could not be done if they were potted in large pots at first and sub-divided before re-potting again.

Last year we had a number of small bulbs which we placed in a cutting-box, started them into growth afterwards, and subsequently lifted and potted them in 3-inch pots. They were handsome little specimens by the month of July. Although it

may be well to pot a quantity to see which of them will grow best, yet I would not advise more being potted into larger pots at the second shift than can actually be grown well, as in the case of *Caladiums*, like many other plants, it is better to have a few well-grown plants than a number of bad ones. In repotting the second time those which have been started in 6-inch pots may be transferred to 8-inch ones. Careful draining of the pots must be observed, and the potting mixture at this time should consist of fibrous loam, with a liberal addition of horse droppings and silver or coarse river sand. The mixture must not be too fine, and it may be rammed very firmly into the pots. Plunging in bottom-heat is an advantage in starting the bulbs, but I do not approve of it afterwards, as, although it pushes the plants rapidly into a large size, they are not robust, which is the stamp most suitable for amateurs and small growers whose *Caladiums* cannot always occupy a warm stove. The largest *Caladium* plants I ever saw were some specimens which had always been grown in a strong bottom-heat, but one day they were taken out to compete at a show, and before the judges reached them the large flabby leaves were hanging over the pots and resting on the stage, and thus the largest plants in the show were consequently left prizeless, as the awards went to sturdy specimens which were admirably adapted for conservatory decoration. It is these which all should grow, and after the second potting, do not replunge, but merely put them in a warm place, syringing freely until they begin to root anew and then administer water liberally. Retain them in a temperature of 65° or 70° until the foliage is well developed, and then they will bear being placed in the warmest end of the greenhouse or conservatory; in fact, from July until the end of September they may be used in these structures, and if placed in more heat in autumn it will prolong the display of leaves. Very handsome little specimens may be grown in 8-inch and 9-inch pots, and we rarely pot them in 10-inch or 12-inch pots, unless very large plants are desired. When the pots are full of roots it is almost impossible to overfeed them with manure water, and the highly beneficial effects of this render the use of large pots almost unnecessary. I never knew *Caladiums* to be infested with any kind of insect, and the trouble of keeping them free from pests of this kind cannot be included amongst their cultural necessities.

CAMBRIAN.

Grevilleas as flowering plants.—Some of the *Grevilleas* are the most persistent flowering of hard-wooded greenhouse shrubs, and among those that bloom nearly all through the year, one kind—*G. Preissi* is at its best during the autumn and winter months. The flowers of all of them are peculiarly curved and borne freely, except those of *G. robusta*, which in most gardens is the only representative of the genus to be met with. This is cultivated for the sake of its foliage, which renders it available for sub-tropical work in summer and for many other purposes, as the quantities brought into Covent Garden Market will testify. *G. rosmarinifolia* is a dense-growing shrub with closely packed clusters of flowers at the end of every shoot. The flowers are of a reddish purple colour, and last a long time in perfection, besides which a succession is kept up for months. In a warm greenhouse this is now in bloom, but under less favourable conditions it is not so far advanced. This *Grevillea* is one of the hardiest among Australian shrubs, for in the south and west of England it will survive the winter out of doors; indeed, the finest specimen I have ever seen was an open-air shrub on the south coast of Devon. Another species of equal hardiness, and flowering at the same season, is *G. sulphurea*, a dense-growing bush with pale yellow-coloured blossoms. A specimen of this against one of the walls at Coombe Wood survived many winters, and flowered profusely every year. Like *G. rosmarinifolia*, it will flower at this time under glass. *G. crifolia* is a dwarf, dense-growing kind with needle-like leaves. The flowers are borne very freely, and are of a bright red colour. As a pot plant it is very suitable, as under favourable conditions it blooms profusely,

and that, too, during the early months of the year. *G. punicea*, a bright red-flowered species, is very showy, but it appears to be a scarce kind. *G. Preissi* is, from a foliage point of view, quite different from any of the others, the leaves being very finely divided, while the growth of the plant is free and open in character. The flowers are borne in dense terminal clusters, of a bright pink colour, with a very prominent curved style of a much deeper hue. This *Grevillea* is also known under the name of *G. Thelemoniana*.—T.

Asparagus plumosus. This elegant climber, although generally treated as a stove plant, will succeed well in an ordinary greenhouse, and seems to do best trained loosely on a flat surface. We have a large plant here which covers nearly 100 square feet of the back wall of a greenhouse. The main shoots only are tied in; the others are allowed to grow at will. It is most useful for mixing with cut flowers, as it lasts a long time when cut, even when the stalks are not in water. It will also stand a few degrees of frost without injury, provided there are no young growths on the plant. We had some very severe frosts in December last, and our heating apparatus having got out of order, on several occasions we had 3° of frost in the house where this *Asparagus* was growing. *Chrysanthemums*, *Heliotropes*, and other plants were cut down while it remained uninjured, and it is now growing as freely as ever I have seen it in a stove. Another advantage in the greenhouse treatment is, that it is not so liable to be attacked by the mealy bug, which generally infests it so much when grown in a warm house. It grows well in a compost consisting of rough fibrous loam, leaf-mould, or rotten manure and coarse sand. As it is a gross-feeder, liberal supplies of manure water will greatly benefit it.—C. RUSSELL, *Inquire Hall, Sedbergh*.

Culture of perpetual Carnations.—When the cuttings, rooted in a hot house during winter, have been hardened in a pit or a greenhouse, they can in April or May stand a long journey without earth at the roots and packed in damp Moss. On arrival the roots must be dipped in water, and immediately planted in a very airy situation, and shaded for five or six days if the sun is hot. They must be kept moist, and when they are in a growing state watered from time to time with liquid manure. When they are about 3 inches or 4 inches high they must be pruned to at least half their size to obtain side shoots and flower-buds. To get plants to bloom in winter and up till April and May, they must in autumn, about the middle of September, be taken up and potted in 6-inch pots, and put on bottom heat in a pit or stove, kept close for about a week, and then aired gradually, when the weather permits, for another week; afterwards as much air as possible must be given, provided there is a temperature of 5° or 6° centigrade (about 40° Fahr.). Of course, the plants destined for this purpose must have a good quantity of flower-buds when taken up from the open ground, and some will have, if properly treated, as many as sixty to eighty. When the buds begin to expand the plants can be used for indoor decoration. Of course, the plants which the first year do not bear a sufficient number of flower-buds must not be potted, and if the winter appears to be severe they must be lifted from the open ground with a ball of earth adhering to the roots, and put close to one another in a pit, uncovered as long as possible, and when frost sets in, covered only to be protected against it, and aired as much as possible. These plants will thus produce flower-buds, and may be potted in March or April and become fit for indoor decoration. If the plants are potted and put in a stove or on bottom heat before they have a sufficient number of flower-buds they grow straggling, lose their leaves, and will bloom badly.—JEAN SISLEY, *Monplaisir, Lyons*.

SHORT NOTES.—STOVE AND GREENHOUSE.

Best manure for pot plants.—Will you have the kindness to inform me in THE GARDEN which of the following manures, viz., guano, nitrate of soda, and sulphate of ammonia, is the best for pot plants, naming them according to their respective merits?—W. M.

Pretty Polly Pelargonium.—Forty years ago, ere zonal and large-flowered Pelargoniums had become so common, the old Pretty Polly, in conjunction with Uniques, Diadematus, &c., were ranked amongst our best greenhouse flowering plants. In those days also a collection of the various cut-leaved and specially sweet-scented Pelargoniums was found in many gardens. We cannot find fault with the changes in taste which the introduction of new things and the whirligig of time brings about; but if those who want specially pleasing objects would take to the Pretty Polly and its old flowering congeners, and grow them as pyramids for lawn and terrace decoration, they would be charmed with the effect produced. Very fine examples of this form of culture of these old favourites may still be seen at Glen Eyre, Southampton.—A. D.

SEASONABLE WORK IN PLANT HOUSES.

SEEDLING FERNS.—Several of the best decorative Ferns are most useful when not too large, and of these stock should be raised from time to time. Amongst these may be named *Lomaria gibba*, *Pteris cretica*, and its variegated form, *P. serrulata*, *Adiantum cuneatum*, and the gold and silver *Gymnogrammas*. Where spores of these and other kinds of Ferns were sown last summer, the little plants will now require pricking off, as, if allowed to remain too long in the seed-pan, they get crowded together and much weakened, in addition to which their roots become entangled to such an extent that in separating them their roots are very much injured. Seedling Ferns may be treated in two ways: either prick them off in pans, or boxes, a short distance apart, and after they have made some growth, pot them. When the seedlings are small it is best to adopt this course, but where large enough, so that their roots will be able to occupy the soil within a reasonable time, it is better to put them in small pots at once. Ferns are not particular what material is used to keep the soil open. I find that coal cinders, broken to about the size of horse-beans, are as good as anything. Where the plants are required to attain size in little time, they must be pushed on in a growing temperature; keep them where they will get plenty of light, and do not shade more than is necessary to prevent the fronds getting injured by the sun. In the cultivation of Ferns that are ultimately to be used in cold houses, living rooms, or for cutting, there is no greater mistake than growing them with insufficient light and air, as, under such conditions, they are much less enduring.

CYANOPHYLLUM MAGNIFICUM AND SPILE-ROGYNE LATIFOLIA. When these two fine-leaved subjects were first introduced, most cultivators of stove plants were anxious to possess them. Now they are seldom met with, as when well grown their noble foliage never fails to be attractive in addition to the contrast they present to everything else. It is only whilst the plants retain their leaves down to the base that they are seen to the best advantage; consequently, it is advisable to propagate them annually, so as to always have young stock coming on to take the place of the old plants, and which, except where very large examples are required, may be discarded. Cuttings, which a healthy plant will produce freely from the lower joints after the top has been removed, should be taken off when they have made a pair of leaves each; they are best put singly into 3-inch pots filled with a mixture of peat and sand. These two plants require the same treatment; viz., plenty of heat, rich soil, a moderately moist atmosphere, shade in bright weather, and, if large specimens are wanted, they must not be stinted for pot room. Plants that have been headed down to within a few inches of the bottom, and after they have broken are partially shaken out and placed in new soil, make the handsomest examples, as in their case the lower leaves are larger than it is possible to get young stock to produce. Where small, or medium-sized plants are wanted, all that is necessary is to restrict the roots by giving smaller pots.

POTTING OFF CUTTINGS OF STOVE PLANTS.—Where an extensive collection of these is grown

this work requires frequent attention during this and the ensuing month, for as soon as cuttings are well rooted, especially when a number have been struck together in one pot, they need separating, as, if allowed to remain, the roots get entangled, so that they cannot be got apart without injury, and in addition, time is lost in getting the young plants established.

CORDYLINA INDIVISA. Although this *Cordylina* is one of the handsomest of all the fine-leaved plants that will thrive in a greenhouse temperature, it has still always been comparatively scarce, owing to the fact that it is not so easily kept in good condition as many things. It likes to be kept a few degrees warmer in the winter—say, about 15° in the night than most greenhouse plants require, as when cooler than this its roots, which are always impatient of moisture, are more likely to suffer. Young plants that have come safely through the winter and that need more root-room should now be potted. Good rich loam with a little sand is the best material for it. Its fleshy roots are more susceptible of injury, if much disturbed, than most things; consequently, when re-potting, it is better to remove one of the old crocks from the bottom of the ball. The soil must be rammed well into the pots, otherwise it will hold water to an extent that endangers the health of the roots. It is better to keep on the safe side by under rather than over-watering. Plenty of drainage must be used, so as to admit of the water passing freely off. As the season advances and growth is more active, more water may be given, but at all times it must be applied cautiously; in this respect this *Cordylina* requires treating much in the way that *Ficus* do. Manure water greatly assists the plant, causing the leaves to come much larger.

CASSIA CORYMBOSA.—Independent of the usefulness of this plant for covering back walls in conservatories and greenhouses, it is one of the best late summer-bloomers we have for flowering in pots, coming in as it does when the bulk of the earlier things are over. Cuttings put in now and grown on with a little warmth during summer will make nice flowering examples next year. Old specimens that are turned out in borders and used as coverings for walls in the way already mentioned produce an amount of bloom that would scarcely be credited by those whose experience of this plant has been confined to pot-grown examples. But to keep large plants that cover much space in sufficient vigour to bloom as they should, they must be well supplied with manure water from this time onwards until they come into flower. The wall on which this *Cassia* is grown should not be too much darkened by other things grown in the body of the house. The present is a good time for turning it out; it does not require so much root room as some things, but the border must be well drained; without this the roots languish, though the plant may not die outright.

CYCLAMENS.—To have these plants in anything like the condition that the market-growers who make a speciality of them produce them in, it is necessary to treat them wholly different from the way that used to be considered right. Under the old course of management, where no more warmth was used than a cool greenhouse affords, double the time was occupied in reaching a flowering stage than is taken under the treatment now practised. From the time the seed is sown in summer, all on through the autumn and winter, alike during the ensuing spring until there is enough sun, fire-heat must be used to keep the house or pit in which they are located in an intermediate temperature; and again when autumn comes round a like amount of fire-heat must be employed, as by the end of the year, or in about eighteen months from the time the seed was sown, they will be commencing to flower. The secret of success is in keeping them going all the time, winter as well as summer. To do justice to them a small pit should be set apart for them, or whatever other plants are located with them must conform to the treatment they require. Young stock that as soon as large enough to handle was put in small pots should now be moved into others 3 inches in diameter. Good turfy loam, with

some leaf-mould, old decomposed cow manure, and sand, form a compost that answers for them. Keep them well up to the glass, now giving them a temperature of 55° in the night, with proportionately more in the day-time. A thin shade must be used when the sun is on the glass, giving air in accordance with the state of the weather. Keep the material on which the pots are stood moist, and syringe overhead in the afternoons. So treated, the plants will grow apace and be in a condition for moving to the pots they are meant to bloom in in summer. Plants that are now flowering must be regularly attended to with water, examining them frequently to see that they are free from aphides, which if allowed to remain undisturbed do much injury in little time.

FRANCOA RAMOSA.—The value of this nearly hardy herbaceous perennial can scarcely be over-estimated where flowers for cutting are much in demand. The long feathery sprays of white bloom which the plant, when strong, produces freely, are an acceptable addition to any arrangement of the choicest flowers. Where a stock is required, if there are no old plants to propagate from, seeds should at once be sown in a good-sized pan filled with sifted peat and a little sand, covering the seed thinly. Stand in an intermediate temperature, covering the pan with a sheet of glass until the plants are up. After this they should be kept close to the glass, giving enough water to keep the soil fairly moist. As soon as the little plants are large enough to handle, prick them off in pans or shallow boxes, now using either peat or good loam—this *Francoa* will grow in either—adding some leaf-mould and sand. Keep in a growing temperature until the weather gets warm, when a greenhouse or cold pit or frame will suit them, giving as much air as will suffice for ordinary greenhouse plants. When they are big enough, move them singly into 4-inch or 5-inch pots, using the soil in a little more lumpy condition. Where there are large, old specimens and more stock is required, they may be divided, securing to each of the pieces as many roots as possible; put them singly into 4-inch or 5-inch pots, or two or more pieces may be put together in larger ones. Keep in a little warmth until they have made some progress, after which a cold pit or frame will be the best place for them during the summer. Where the plants are wanted for conservatory or greenhouse decoration, large examples are easily obtained by giving additional pot room as they increase in size; the larger and stronger the specimens are, the more and finer flowers will they produce. T. B.

PROPAGATING.

ARALIAS. The genus *Aralia* is not a large one, yet several different modes of increase are called in requisition to propagate the various species. The handsome *A. Sieboldii* can be readily increased by cuttings of the weak shoots that are sometimes pushed out from the main stem, generally near the base, and which should be taken off with, if possible, a heel of older wood. These cuttings may be taken at any time during the spring or summer months, except just as the young leaves are pushed forth, and they should be dibbled firmly into small pots, the soil being of a light and very sandy nature. In the case of all cuttings the compost used should be passed through a sieve with a quarter of an inch mesh, as any irregularities in the soil will prevent the cutting being inserted as securely as it should be. When the cuttings are put in they do best if plunged in a gentle bottom heat and kept close till rooted, which they do very quickly. They may also be struck during summer in an ordinary cold frame. In the case of plants that have run up tall and naked, they may, if needed, be shortened by taking off the head and grafting it near the ground, the stock employed being the base of the same plant. The naked stem may be either cut up into lengths after the manner of *Drazenas* or divided into single eyes, as is done with *Vines*. All the above methods are available for the increase of the variegated as well as the green-leaved form, but of this latter seeds are sometimes obtained, and when that is the case quantities

of plants can be raised without difficulty. If the seed is sown as soon as ripe it germinates quickly, but should some time elapse before it is placed under conditions favourable to growth it will often lie in the ground for a lengthened period. *A. papyrifera*, which is very ornamental as a foliage plant, and interesting as being the plant from whence the Japanese rice paper is prepared, can be readily propagated by cuttings of the roots, a mode of increase that is also available for the hardy *A. spinosa*, the last especially growing with the greatest freedom in this manner. For cuttings the stouter roots should be taken and cut up into lengths of an inch or two, taking care when this is being done to keep the upper part of the roots all one way, for it is in many cases difficult to distinguish between the upper and lower portions when cut up, and should they be put in upside-down, failure will be the result. These pieces of roots should be dibbled in pots or pans of soil, and just deep enough to cover the upper portion of the root. If treated as cuttings of the branches, they quickly push forth leaves from the upper part, and numerous fibres from the lower portion. When sufficiently advanced the young plants must be potted off. The stove kinds of *Aralia* include among their number some with beautiful foliage, foremost among them being *A. Veitchii* and its variety *gracillima*, which can only with great difficulty be struck from cuttings, and layers take a long time to root. In that case it is necessary to graft them on some allied kind, and the stock generally chosen is *A. reticulata*, of which cuttings root readily. The grafts chosen should consist of the upper part of a shoot in little more than a half-ripened condition. It may be inserted either by fashioning it in a wedge manner and splitting the stock for the purpose, or by side-grafting. This last is to be preferred, as it is not necessary to cut down the stock till a union is complete, so that should the graft fail the stock is still available for another. At the same time, if the stock when left entire is too tall for the propagating case, it may be shortened back to half its height without injury. For side-grafting a slight incision is made in the stem at about an inch above the soil; then the same distance above this cut insert the knife, and make a slanting cut down to the first incision. The graft must be fashioned in such a way as to exactly fit into the cut portion of the stock, and then tied securely in position with soft grafting cotton. Coarse damping cotton will do very well for the purpose. After the operation is finished the grafted plants must be kept close till a union is complete, when they can be hardened off by degrees, and as soon as the grafts commence to grow the upper part of the stock can be cut away. For grafting, the stem should be from the size of a straw to that of an ordinary lead pencil, and must, of course, be young and vigorous, as when in that state wounds heal rapidly. It will be found a great convenience to have the plants of *A. reticulata* intended for stocks in small pots, as they will then occupy less space in the propagating cases, and also when shifted into larger pots they can be buried rather deeper than before, so that the point of union will be covered with soil. Though several of the other kinds will strike from cuttings, they are generally grafted as above directed, but, except in the case of *A. Veitchii* and its variety, grafting is not absolutely necessary for their propagation, though it is often carried out, from the fact that plants grown in this way attain an effective size in less time than those struck from cuttings. *A. Chabrieri*, elegantissima, leptophylla, reticulata, and the variegated-leaved *A. Guilfoylei* can all be propagated from cuttings; indeed, this last-named strikes freely and may be used as a stock for the others. To strike these different kinds, the cuttings should be formed of the current season's growth, and taken when in a half-ripened condition. A length of from 4 inches to 6 inches is very suitable for the cuttings, and being taken off at a joint and two or three of the bottom leaves removed, all is now ready for insertion. For this small pots are the best, as then each cutting can be put in singly, the foliage being in this way retained in a more satisfactory condition than if several are put together. The pot should be partly filled with broken crocks, and they strike

more freely if some pounded charcoal is mixed with the soil, which should be of an open, sandy nature. The members of an allied genus, *Panax*, some of which are occasionally classed with the *Aralias*, all strike root readily from cuttings.

CHOISYA TERNATA, that has been grown under glass to get the blooms early in the season, will be by now studded with young shoots, which strike root quickly if taken just before they become woody, and treated the same as most soft-wooded cuttings. One particular thing to bear in mind is that, like the variegated *Coprosma Baueriana*, this *Choisya* suffers greatly if the cuttings are at any time allowed to flag, so that they should be put in quickly when separated from the parent plant, and kept well attended to in the matter of water and shading afterwards.

COREA SCANDENS VARIEGATA is a plant that puzzles a great many to propagate, for even where it seeds the plants always die during their earlier stages, and it is by no means the easiest of subjects to strike from cuttings, although this is the method generally employed. The best results are obtained by taking the cuttings at this season, selecting for this purpose the weakest shoots available, as many of the large and stout ones will be almost certain to decay. If the shoots are small they may be inserted entire as cuttings, while in the case of the larger ones two joints should be allowed, leaving one from whence the leaf has been removed for the base of the cutting, and the other with the foliage entire for the upper portion. At the same time I have had a fair measure of success by putting in single eyes, and when this is done stouter shoots can be used, but it is more risky than with the smaller ones. In any case the cuttings may be dibbled around the edge of 4-inch pots, which should be well drained for their reception and filled, but not too firmly, with open sandy compost. The single eyes must have a piece of the naked stem below the leaf allowed to remain on, and this being inserted till the eye is just on a level with the soil will serve to keep all firm and secure. After this the cuttings must be placed in a close case, such as is used for ordinary soft-wooded propagating. The cuttings need careful attention in the matter of shading, air-giving, watering, &c. As the cuttings are very delicate, little air must be allowed to reach them, while, on the other hand, damp and decay must be especially guarded against. A friend of mine who had often unsuccessfully attempted to strike this *Coclea* propagated several by layers, and this method possesses the advantage of requiring but few appliances. A branch or two were loosened, and the shoots layered in 3-inch pots, the buried portion of the stem being cut through for a little distance.

THE OLEANDER (*Nerium Oleander*) and its many varieties strike root if the young shoots are taken and treated as other cuttings, but besides this they possess the peculiarity of striking just as freely in water alone if a piece or two of charcoal is placed therein to assist in purifying it. In the case of cuttings that are struck in water the roots are more delicate than those produced in soil, and require great care in potting them for the first time. T.

Seeding Primulas in the open air.—The placing of *Primulas* in the open air for the purpose of securing a good crop of seed is not, I believe, generally adopted. A large trade grower of my acquaintance stands the plants out of doors early in May, and allows them to take care of themselves, as regards the impregnation of the flowers, with the result that quite as good a crop of seed is secured as from plants which have been altogether grown under glass and the flowers fertilized. When the plants are first placed out doors they are slightly protected at night in all weathers. The plants do not remain out of doors until the seed is ripe, as, if so treated, much of it would be lost. Besides saving the labour of fertilising the flowers this plan saves a good deal of labour in watering, and at the same time renders the space they occupied available for something else. The seed of the plants which are intended to be treated in this way may be sown about the middle of July. J. C. C.

FLOWER GARDEN.

AN AUSTRALIAN BOTANIC GARDEN.

WE engrave this very pretty view of the Botanic Garden at Melbourne, and wish we could give our readers as good an idea of the floral treasures of the Australian woods. The flowers of the land have charms one would never suspect from the way the plants have been grown in our gardens. Pinched carefully, and all their charm and variety of habit reduced to a cushion, one has no idea of their beauty. The drawings brought over last year by Mrs. Rowan showed us how graceful the Australian flowers are when growing in their own way in the bush, and made us long to see them. We have just heard from our friend Charles Moore, of Sydney, who has been over forty years director of the botanic gardens there, and hope he will some day send

varieties, as these have hard, wiry habits of growth, bloom most profusely, and come freely from seed also.—A. D.

VISIT TO A NARCISSUS GARDEN.

WHILE on a visit recently to the south of Ireland, I had an opportunity of visiting the Narcissus grounds of Mr. W. B. Hartland, and though I was pretty well acquainted with his bulbs from his "Little Book," and from having for several years purchased bulbs from him of any of the newly discovered and recently sent out varieties, I was quite unprepared for the feast that was before me. To see the masses of the rarest varieties in such luxuriance and health was a sight not elsewhere to be met with; and above all others this garden is rich in the finest forms of white Trumpet Daffodils. There are some, too, which I expect to hear more of at a future time, and which are not yet obtainable. The vigour and health of the stock all round are enough to induce one to replenish his own garden from such a

culture. The soil and situation of this garden are most favourable to the production of sound and well-matured bulbs, on which the future results in our private gardens altogether depend. Leda, Bishop Mann, and other white Daffodils attain to a height I have not seen equalled anywhere—from 18 inches to 2 feet. Amongst the vast numbers of *N. princeps* (naturalised in Ireland) are found many fine forms, golden, bicolor, &c., so interesting to lovers of the Narcissus. Gerard's double pseudo-Narcissus was well represented by a large bed having quantities of beautifully-shaped perfect blooms.

As my visit was for the purpose of comparing and observing Narcissi, I shall only add that this garden is also noted for rare Hellebores, Primroses, and Polyanthus, which would require a separate notice to do them justice.

A MEMBER OF NARCISSUS COMMITTEE.

Mr. Hartland's Daffodils (p. 297).—In justice to the numerous gentlemen who gave some con-

View in the Botanic Garden, Melbourne, Australia. Engraved for THE GARDEN from a photograph

us some views of his beautiful gardens there, or the plants growing in them.

Petunias.—"Cambrian" in THE GARDEN of March 19 (p. 247) wrote of Petunias as bedding plants in strong terms of disapprobation. It is very likely that in a wind-swept region, and specially where rain is excessive, such strong growers in good soil as Petunias are would do badly. But in many other localities where the wind is less fierce and the rain less persistent, we find beds of Petunias singularly effective and enduring. These plants do best in rather poor soil, because being naturally strong growers they need no stimulants. They bloom early and with wonderful profusion, and if a heavy rainfall does demoralise the flowers, a day of sunshine soon puts all to rights, and the bed is as gay as ever. The large-flowered, and more especially the double kinds, are unfit for bedding. The best are the smaller flowered striped and sel-

source. The profuse bloom of large masses of *N. capax*, the most distinct in form of all the double Daffodils, was a wonderful sight. So early is the bloom in that favourable district, that the myriads of Ard-Righ (Yellow King), some 20,000 in number, were almost all gone out of bloom.

Rip van Winkle was as bright a golden colour as any double *N. Telamonius*. When seen well grown and coloured, as it is here, and as I have it myself, it is a charming little flower, very distinct and most useful for cutting from. The woodcut of it in THE GARDEN (Feb. 21, 1885) is a faithful portrait of the form.

Large masses of the miniature white Daffodil Minnie Warren, which has also been figured, were most beautiful. This I have found very useful for pot culture. Many thousands of *N. moschatius*, collected bulbs from the Pyrenees, were producing blooms of varied form so interesting to compare with the large forms as we know them in garden

considerable time and attention to the specimens which Mr. Hartland sent to the last meeting of the Narcissus committee, I must ask you to allow me to reply to his statement that "they could not be reported on, as the English ones for comparison had to be produced from under glass." The twenty-four varieties which we received from him were gone through most carefully, and I wrote him on the following day a full account of our opinion concerning them. Some were varieties well known to us, others were varying forms of collected species, such as have been received in great numbers lately. One seedling we considered worthy of a distinctive name, and two others we requested to see again. It is true that we could not decide about one variety sent as Ard-Righ, because we had no flowers of Yellow King with which to compare it, but for the white sorts we were pledged to a competitive trial before giving any further names. If the distinctive points in Mr. Hartland's Daffodils are to

disappear when they are removed from his garden and planted elsewhere, I fear it will be of little use our troubling ourselves about them in future. We are perfectly ready to admit that many of the flowers which he sends us are distinguishable from one another, but of course that does not mean necessarily that they are worthy of distinctive names; far from it; the distinguishable features are often points of inferiority between one and the other. The large number of sources from which flowers are sent to the Narcissus committee, and the grateful letters which I receive in answer to our reports give one great encouragement in believing that our work is generally appreciated and of use, and I am sorry that we should have failed to give satisfaction to one who loves these flowers so well, and who possesses so many that are worthy of all attention.—C. R. SCRASE-DICKENS, *Hon. Sec., Narcissus Committee.*

PRIMROSES.

I THINK it was Mr. Douglas who said the other day that it was necessary to the successful culture of hardy Primroses that they should have shade. That is perfectly true as concerns the common or wild Primrose, for it is a weakly thing at the best, and fares badly when grown under the fierce light of day. Naturally a retiring, timid sort of plant, it thrives best in quiet and in shade, but still it likes a cool or holding soil, where the Oak strikes deep and the Hazel and the Bramble thrive luxuriantly. The garden Primrose, if I may adopt such a term, is so diverse from the wood variety, that it seems to thrive best in broad light and flower in the full glare of the sunshine. That, at least, is my experience of it. I do not think that, with the strain which beautifies our gardens now in such rich-hued variety, there is much that is allied or in common with *Primula vulgaris* beyond the fact that it is a family connection. As far as my own kinds are concerned, that beautiful mountain form once known as *Primula altaica*, and without doubt a distinct form of some foreign Primrose, is the chief or seed-parent; and from that, fertilised with what is probably the single red form of the double crimson Primrose, and better known as *Primula auriculiflora*, has come most of the rich-coloured Primroses I now possess. I fear the origin of these two forms which I have named is somewhat lost in obscurity; but at least both have been well known as exceedingly beautiful ones, and if not so common now is due perhaps to the fact that their progeny have given seed somewhat freely, and seed, again, has produced myriads of varieties, all so fine and beautiful as to leave the parents somewhat in the shade. The increase of Primroses by mere division has proved an exceedingly difficult matter. A season or two may prove specially favourable, and yet another season or so may prove very destructive. I write of a stiff soil, which retains water in the winter like to clay, and in the summer becomes quite baked—both conditions peculiarly adverse to the growth of Primroses. Winters, however wet or severe, are seldom so harmful as great heat and drought, because then trips are pretty sure to be rife, and with the loss of leafage comes bareness of crowns, and never afterwards the robustness which previously existed. Last year was a very favourable one, as not a leaf suffered, although the earlier portion of the summer was hot and dry. It happens, however, that plants suffer least before the middle of July, and worst later if the end of the summer be a parching one. However, it is satisfactory to be able to record the kindliness of one season at least, and I hope many more similar ones may follow. As a result, I can show now one of the most beautiful beds of Primroses I have yet had. There may be some 600 strong plants in the cluster, and, with very few exceptions, all of fine quality and blooming profusely; hence it is proved that hardy Primulas will thrive without shade, for I have none, neither do I wish for any.

From the time of making the cross mentioned, several years, perhaps some twelve or fourteen years since, till now I have fertilised no more Primroses. So far, the mere process of selection seems to answer every requirement, for I always

select seed from the finest, richest coloured and chiefly thrum-eyed flowers. No doubt some very interesting information might be obtained in regard to the capacity of thrum-eyed and pin-eyed kinds to reproduce their kind, but busy people can hardly give attention to matters of that sort. Still further, it would be interesting to note what would be the relative proportions of similar flowers from a thrum and pin-eyed cross. Saving chiefly from thrum flowers, because these please me much the best, I find that, on the whole, about one-half the progeny has thrum eyes. But the most satisfactory result is found in the evident gradual improvement of the strain in size and quality of flower through selection from the best flowers for seeding alone. The greatest difficulty is the tendency of the strain to produce Polyanthus stems and clusters. That feature may be due to race, for nearly all members of the *Primula* family carry their flowers in clusters on tall stalks, and this development is but the lengthening, by constant breeding, of the stem, which undoubtedly exists, though in a shortened form, in all true Primroses. It is very possible also that there may be some of the Polyanthus strain running in these coloured Primroses; hence the tendency; and there is the suggestion that as Polyanthus are largely grown near, the infusion of Polyanthus blood through insect agency is inevitable. Of course, all these tall-stemmed kinds are beautiful, but they are not real Primroses. But then in some years the tendency seems more marked than others, as thus the present season's bloom gives 90 per cent. true; that of the previous year was much less favourable, so that it is fair to infer that local causes operate more or less. This much, however, may be said, that it is a hundred times better to trust to seed as a means of perpetuating Primroses than by division or propagation. That much, at least, as far as the southern districts are concerned. Farther north, or in moister regions, diverse conditions may enable plants to thrive after division freely. We know that in some favoured localities the choicer double Primroses do well, and there the best single kinds may thrive well also. On the other hand, I think it doubtful whether seed would in colder or moister districts be freely produced. Here, apart from excessive drought such as now and then occurs early in the season, the greatest enemy to seeding of Primroses is found in late white frosts, the which have sometimes done great harm, but then chiefly when unduly mild winters have excited the plants into very early bloom. Very often have they been a month earlier in blooming than they are this year.

Mention of the effects of frost also reminds me of the fact, that whilst whites, reds, carmines, or similar striking hues suffer least, the deep crimsons, and specially the bluish-tinted flowers suffer most. I worked for blues largely a few years since, but found the defect I refer to so marked, that I have now omitted to select seed from them. Of all colours, especially on sunny days, none tell like the bright reds or reddish crimsons; hence I prefer to save from those tints as much as possible, because these are certain to retain their own hues largely, and yet give many other tints also. Next to these come the pink and carmine hues, the pure whites, and last the pretty tinted lilacs. Of course, all in combination reproduce all sorts of hues, but the above ones predominate. In sowing seed much is gained by doing so as soon as it is well ripened. Gathering may not always be left until the seed is dead ripe in the pod, as much will then inevitably be wasted; still, some will be riper than the rest when it is gathered. A fortnight's exposure under glass in paper bags usually makes the ripeness of the whole even, when it may be rubbed out and fairly cleansed of refuse, and with yet, perhaps, a few days' more exposure to fully harden it, is ready for sowing. Thus, the end of July perhaps is reached, but seed properly sown in shallow pans or boxes and in fine sandy soil, then placed in a frame and lightly shaded during hot sunshine, will germinate freely in about three weeks, and in a few weeks more the plants are strong enough to dibble out either into frames for the winter, or, if preferred, into the open ground. Primroses do not make any considerable amount of roots in the autumn, and may be lifted or disturbed appreciably in the soil

should severe frosts ensue. For that reason it is wise to winter in frames where the plants are encouraged to make growth, and early in the spring they may be dibbled out into their permanent quarters. As spring is the real rooting season, of course they soon become established, and stand the ensuing summer heat well. It is quite easy to ensure that a large portion of the plants will bloom the first spring, or within eight months of sowing, but the real character of the plants is best seen the following year, when being strong they bloom profusely.

A. D.

THE NEW ZEALAND FLAX (PHORMIUM TENAX) IN IRELAND.

AFTER the very severe winter we have just passed through, a few words in favour of the above plant can hardly be out of place. Here it has stood out, unprotected and exposed in several positions, without receiving the least injury, and I am sure, if better known in the south and west of England, it would be more generally grown. We find the leaves last a long time when cut and mixed with the flowers of Pampas Grass, with a spike or two of late *Gladiolus* and *Tritoma glaucescens*. The latter flowers here until Christmas. The above combination in tall glasses, with a few sprays of trailing Ivy to partly conceal the glass stem, has a very pleasing appearance. Planted out in clumps in rich deep soil or on the margins of ponds, where the roots have free access to water, the New Zealand Flax grows freely, and gives a tropical aspect to the landscape which few other plants can excel. When the leaves are ripe, we find them most useful for tying when cut into thin strips, the fibres being very strong. The plants flower and ripen seed very freely.

My experience of the variegated forms is that they are more hardy than the green variety, and in localities where their hardiness is doubtful they are quite worthy of a place under glass. If potted in rich tenacious loam, they will well repay for the little care necessary to keep them in health by giving a pleasing feature to the too-often formal arrangements of plant-houses. I am of opinion that the forms we now have under cultivation are only seminal varieties. I have a quantity of seedlings raised from *atro-purpureum*, many of which are quite as dark as the parent, and many from the same seed-pods are of a light green. I also find that after several years the variegated forms revert to the old green variety, especially when grown in a rich, moist, deep soil.

W. OSBORNE.

Fota Island, Cork.

Allium neapolitanum.—Though the genus *Allium* is a large one, but few members of it are worth growing for their ornamental qualities, and still fewer if a disagreeable odour be taken as an objection. In *A. neapolitanum* this is wanting unless the stem is bruised; indeed the flower possesses a rather agreeable perfume. It is a remarkably free-flowering species, and very useful as a hardy border flower, and what is more it can be very readily forced into bloom, which under glass will remain in beauty a considerable time. The flowers are borne in good-sized clusters, and individually they are about an inch in diameter, pure white in colour, on which ground the dark-tinted anthers stand out conspicuously. It is a plant of the easiest possible culture, and great numbers are now imported into this country for forcing purposes, all that is necessary being to pot them in fairly good soil, and after they are well rooted introduce them into a gentle heat. About half a dozen bulbs in a 5-inch pot will yield a good display. H. P.

Seedling Hellebores.—These do not always take five years to blossom, as mentioned in a note on Hellebores in THE GARDEN on April 2. In September, 1885, I sowed a box of Hellebore seed, covering it with slates and removing to a cold frame in November. During the next month and January, 1886, the seeds came up freely and were planted out the following June. In January, 1887, that is, a year and four months from the time of sowing, eight of them sent up strong flower-stems, and no doubt the remainder will all blossom next December.

The young plants are seedlings of *H. angustifolius*, crossed with *H. maximus* and some of the fine new Bath varieties. Among the eight blossoms, two were pure white, bowl-shaped, with green stigmas. The third, a blossom of lovely form, pure white with pink stigma, and the remainder pure white with pink tinge on the outside of the petals and pink stigmas. All the plants appear to have reddish brown mottled stems. — L.

THE GERMINATION OF SEEDS.

IN his book on "Alpine Flowers," Mr. W. Robinson, under the head of "Raising Plants from Seed," gives this very necessary caution: "Many seeds come up a long time after others; in fact, seed-pots are often thrown away, on the supposition that the seeds are dead when they are perfectly sound, and some will come up a year or two after being sown. All that is necessary with the seeds that do not come up during the spring is to give them an occasional watering, and to guard against the growth of the Lichen-like *Marchantia*." I have just had an illustration of the truth of this remark. Last summer the Rev. A. Rawson sent me from Windermere a few seeds of a fragrant form of *Primula Auricula* he had raised, asking me to sow them, but stating that he feared they would hardly germinate. In about six weeks I had three plants through the soil, but I kept the seed-pot all the winter with a piece of glass over it, and surfaced it about twice with a little silver sand. As soon as my *Auriculas* in the same house commenced to be active I gave the seed-pot a good watering, and again placed the piece of glass over it, doing this rather with the intention of encouraging the three tiny plants to grow rather than expecting that more seeds would germinate. During the past fortnight quite a crop of tiny seedlings has come through the soil, and so numerous are they that I think every seed must have germinated. Had I thrown the pot away in the autumn, I should have lost nearly the whole of the progeny. For some time past I have made a practice of keeping all my seed-pots of *Auriculas* from twelve to fifteen months in order that opportunity might be afforded for the seeds to germinate, if any have not done so, and I invariably secure a crop of stragglers, and I have the impression that these later developments may comprise the very flowers of the flock. I remember once hearing of a gardener who sowed some seed of herbaceous *Phlox* in a pan, doing it in early spring, and then placing it in heat. After keeping it four or five months, and finding that not a single seedling put in appearance, he threw the contents away on the ground of a shrubbery border. Judge of his surprise when passing the spot a few weeks afterwards to see lots of seedling *Phloxes* putting in an appearance, and an excellent crop of plants rewarded him. Since that time he has carefully kept his seed-pans and pots long enough to give the contents a fair chance of germinating. R. D.

Chinese or Indian Pinks.—The fact that these charming and varied perennials flower after the ordinary *Carnations* and *Picotees* have gone out of bloom is one among many reasons why they should be grown. They lack the fragrance of *D. caryophylloides* it is true, but then they are easily grown, remarkably free, and very persistent. *D. chinensis* gives us double and single forms, some of which have been considered good enough to name. A little seed sown thinly in the open air in good soil soon produces plants, and these should be thinned out, and then a good top-dressing of siftings from the potting bench placed on the surface. This is found very helpful. *D. Heddewigi* and *D. laciniatus* are but fine large single forms of *D. chinensis*, the latter having charmingly fringed lacinated flowers, and both give varying colours. Of *D. Heddewigi* there are two fine rich-coloured varieties, viz., *Crimson Belle* and *Brilliant*, the latter a fine vermilion selection from the former. During the past two or three years a pure white variety has appeared, and if it can be permanently fixed it will prove an excellent addition to the group. *D. hybridus*, double blood-red, or *atrosanguineus* is a plant that should have hosts of admirers, so fine

and rich in colour is it. It appears to be intermediate between the Indian and the Mule Pinks, the flowers double and of a rich crimson colour. A small packet of seed can be had very cheaply, and there is no difficulty in getting them to grow. — R. D.

DAFFODIL NOTES.

THE season of the Daffodil is again upon us, and in about a week or so we shall be gay with white and golden yellow trumpets. A few of the smaller trumpet forms, such as minor and minims, are already past, but they can hardly be said to commence the season. I consider the first early to be *obvallaris*, the Tenby Daffodil. This is one of the most useful Daffodils in cultivation. It is of a good colour and has a stiff form, which is very requisite in a Daffodil when it is required for carrying purposes. It is also a fair grower, but is not quite so satisfactory in this respect as might be desired. I have seen whole beds of it almost entirely disappear without any apparent reason. In the autumn of 1883 several beds were planted with this variety. They came up well and flowered splendidly next spring; in fact, everyone who saw them considered them a picture of health. The summer of 1884 was very dry and scorching. This is generally supposed to be favourable for most bulbs, as tending to ripen them; therefore, a fine display was expected in 1885. But on examining them about the month of February, I found they were coming up very irregular, whole patches of them failing to put in an appearance. On digging the ground where they had failed to appear, I found some bulbs half rotten, but could find no maggot or any other vermin which might account for it. The time of blooming of the Tenby Daffodils varies very much in different seasons. About four years ago the first blooms were picked on February 11, while this spring none were gathered before March 25.

One of the finest introductions of late years is *pallidus precox*. It is quite as early as Tenby, but although they are both found wild, the one in Wales and the other in the Pyrenees, in *obvallaris* I have never yet detected the slightest variation in form or colour, while in *pallidus precox* one can find the forms of nearly all other trumpet Daffodils. I noticed two a few days ago in form almost like Tenby and another similar to *bicolor grandis*. In growth it is, however, not so satisfactory as could be wished for, as in a lot of imported bulbs which have been planted three years, about half has died. Neither is it a very free-flowering variety, as I have seen a bed in which there was not more than one flower to four roots. Yellow King, which is now proved to be the same as Mr. Hartland's *And-Righ*, is a variety well worth growing, and should be in every collection. It flowers a few days later than Tenby, but it has a much larger flower, is a vigorous grower, and above all blooms freely. Golden Spur has a larger flower than Yellow King, and has very long petals which do not overlap. It is not quite such a vigorous grower as Mr. Hartland's pet, but still with ordinary care it can be grown successfully.

Umberto I. and Regina Margherita were introduced from Italy a few years ago, but though novel they cannot be considered very striking. They may be easily recognised by the yellow bars in the centres of the petals of the perianth. Regina Margherita is the largest, most distinctly marked, and altogether the best of the two. I have also seen several other forms from Italy. One or two of them are very good flowers, but no improvement on any of our yellow trumpet forms, and some of them are very puny and weak and unworthy of cultivation. Among them I noticed a princeps almost like Mr. Hartland's, also a nobilis. This last variety varies very much in form and colour. Most of them are very bicolors. One I noticed with a trumpet like Horsfieldi, but with a much narrower and flimsy perianth. One is almost exactly in shape like the pseudo-Narcissus I have seen from Dorsetshire. *Pseudo-scoticus* is another sturdy little flower, and is one of the best of the pseudo group.

A variety, which the Rev. Mr. Wilks calls *trilobis* is a neat-shaped flower, and has a I cautiously im-

ported trumpet. It is to be hoped that it will be brought before the Daffodil committee this spring, and passed as a recognised variety. It is a very free grower and a most profuse flowerer. The common form of *spurius* is now in flower, as are also General Gordon and Henry Irving, varieties which have been picked out of *spurius*. The common form is a most unsatisfactory grower, and is much inferior to the two varieties above mentioned. Mr. Hartland's princeps already shows a few flowers, but they do not possess quite so much weight as the Dutch princeps. It is a moderately free bloomer, and at present its growth is healthy. Double Daffodils show a tendency to become single this season. Among some forced blooms of *Telamonius pl.* which I saw in Covent Garden, I noticed some which were almost single, and a great many of them had the trumpet only half filled. They were from, I believe, English-grown bulbs. For the first time, too, I see that pretty little double *albo-aurea* coming with the trumpet unbroken, and in one or two cases it shows a tendency to turn single. This variety is blooming better this season than I remember it to have done; indeed, it is not a very strong grower at best. *Narcissi* in general seem to be throwing up plenty of flower. That useful variety *Leedsii amabilis* in particular is looking remarkably well, and a bed of them is quite thick with buds. A few warm days would bring on a host of varieties which are now being checked by the biting north-east blasts which we have experienced nearly all last week. Those fine varieties Emperor and Empress and the northern champion *N. Horsfieldi* are, as usual, growing very strongly and showing plenty of flower. D. W.

Flowering branches in water. I have been trying the plan of putting large branches of flowering shrubs such as Lilac cut off in winter and put into a warm house with the ends inserted in water, and it is surprising how well they burst into leaf and flower, so that one would think they were well established bushes with all the roots entire. I have no doubt that many amateurs would find it very interesting to watch the bursting of the buds and gradual development of the leaves, without the aid of a single root, but simply by the moisture being carried up by the sap vessels. I have also some Apple shoots in full bloom that have been put in bottles of water to try if they would root better in water than in soil. J. G. Hoots.

Hypericum olympicum.—In reference to the note of "T. C. L.," on p. 319, about the hardness of this plant, I agree with what "W. G." says, on p. 303, that it is perfectly hardy; that is to say, I have kept plants out in Cheshire through such winters as 1880 and 1881. Its ordinary duration of life in gardens, however, is about three years. It is what may be called an herbaceous shrub, dying to the ground-line in autumn, and breaking from the base about the same time; but when the woody base gets very hard and thick it fails to break again, or the circulation between the roots and young shoots is insufficient to maintain them. Under these conditions it dies, generally in its third or fourth winter, whether the weather is severe or not. It is easily kept by taking a few cuttings every year in spring. I do not find either *H. oblongifolium* or *H. patulum* hardy here unless the winter is mild. If killed to the ground they never recover here.—C. W. Dob, *Edge Hall*.

SHORT NOTES.—FLOWER.

Bromus sterilis aurea.—I have found at Sandiacre *Bromus sterilis aurea*, which I think would look very bright in the spring garden. It is a clear yellow, and comes true from seed.—Wm. Elliott.

Primula altaica.—This seeds but sparingly, and may be known by its thin calyx and its thinner foliage, is more subject to red spider, and will grow in a lighter soil than *Primula vulgaris*. If I am wrong, I shall be glad to be enlightened upon this subject.—W. Elliott.

Will you kindly inform me what would be likely to grow in a dark corner in an angle formed by the walls of two portions of a house? No sun ever gets to it. The walls are covered with Ivy, but the piece of ground in the corner is very bare. Would Lily of the Valley grow in such a place? Or how would it do to form a rockery there, and if this is to

succed, what plants would be likely to thrive in it?—T. CARMICHAEL.

Ranunculus bulbosus.—The white *Ranunculus bulbosus* is a charming British plant I found at Sandiaere, and if it comes true from seed, of which I have little doubt, we shall have one plant more worthy of introduction to the flower garden. I have also seen some very pale forms of *Ranunculus acris* in the same locality. I will report further in the season about them.—WM. ELLIOTT.

THE CHIONODOXAS.

Two years ago I received a large number of bulbs, collected by Mr. Edward Whittall, of Smyrna (the discoverer of *Chionodoxa sardensis*), in the mountains near that place. These are now well established at Brockhurst and are blooming vigorously. The well-known forms of *C. Lucillie* and *C. sardensis* are amongst them, but there are several well marked varieties. One is the pure porcelain white, a real gem, which will be a very popular flower, if it can be obtained in quantity. We have about half-a-dozen bulbs now producing flowers. One form has a delicate pink shade of colour, and another has a delicate blue, but in both cases the flowers are pure white when fully opened. There is a single plant of deep purple, like the colour of *Hepatica Barlowi*. There are many varieties in the shading, from the blue of the *Nemophila*, to white at the centres, and of violet-purple, such as could be picked out in any large group of *C. Lucillie*. The plate in your Vol. XVIII., p. 12, is an admirable illustration, and therein is shown also the white variety, a few bulbs of which had been found by Mr. George Maw on the summit of the Nymph Dagh, near Smyrna. In the *C. sardensis* there is but little variety. It has no shading, the perianth being of a deep even blue. A mass of it has a charming effect, even more beautiful than its sister form.

Mr. Whittall sent with these a large number of bulbs of *Scilla bifolia*, and these have interested me greatly for the last two seasons. I have at length come to the conclusion that they are not *S. bifolia*, and that a new name will have to be found for this variety. They are to be found in any large lot of *C. Lucillie*, if the gardener has not weeded them out as rogues.

The *Scilla bifolia* of our gardens is figured in the *Botanical Magazine* (vol. xx., p. 746), where it is stated to be a British plant. It is also to be found in many illustrated works on British botany. The example here given must have been taken from a garden variety, as it certainly differs altogether from the British plant, having a darker colour and a more diffuse habit. It is, however, not unlike the *Smyrna Scilla*, especially as regards the shading of the perianth from blue to white, as in the *Chionodoxa Lucillie*. It differs, however, materially from the plant, which is dwarfer and smaller in every part than *S. bifolia*.

There is another *Squill* figured in the *Botanical Magazine*, *S. pumila* (pl. 3023), which bears considerable resemblance to the *Smyrna* variety, and this is stated to be a native of Portugal. I have searched in vain through all the plates in our botanical literature, and cannot find any likeness of this *Scilla*. If it is to be called *S. bifolia*, it should be *S. bifolia minor*, but even this would not distinguish it sufficiently. It is very likely indeed to be a hybrid with *C. Lucillie*. It blooms three or four weeks before any *Scilla*, and in colour, whether self-blue or shaded, it exactly resembles it; and it is so like it in habit, that, but for the *Scilla*-like disposition of the stamens, I should have said it was a variety of *Chionodoxa nana*, a plate of which is given in vol. ex., pl. 6453, of the *Botanical Magazine*, taken from a plant found in the neighbouring island of Crete. There is a great variety of colouring, although of a minute sort, in this *Scilla*, just as there is in *Chionodoxas*. Some are self-blue, like *C. sardensis*; others shaded like *C. Lucillie*, which again suggests the idea of their being hybrids.

The *Chionodoxas* seed very freely here, and there are hosts of young plants coming up around the old ones. They also multiply at the roots. The long and cold winter we have passed through has not harmed them in the least. They were our earliest spring flowers, and have continued now over two months in great beauty. The *Puschkinias* are fol-

lowing them closely, and now as they are on the wane the numerous varieties of *Scilla bifolia* are beginning to bloom, following the *Smyrna* variety by at least four weeks. WM. EROCKBANK.

Brockhurst, Didsbury.

THE VISCARIAS.

THE season for sowing our annuals is rapidly drawing near, and no time should be lost when favourable occasions offer. The number of these annuals is increasing rapidly year by year, and it may be well to draw attention to a few of the good, though much neglected, kinds that are still grown in places where they found a home on their first introduction to this country. The class, of which the annexed illustration is an excellent example, will be found useful in many ways besides that of a prominent position in the mixed or annual border. They will also be found useful for sowing over bulb beds, &c., during the summer months. These beds are generally of a permanent character, and would otherwise have an unsightly appearance during

Viscaria elegans picta nana compacta.

the best months of the year. The number of these annuals is now so large, and the habit and time of flowering so varied, that if properly selected and cared for they will give a succession of flower through the summer and autumn months. From their hardy nature they may be sown in the open border any time after the end of March for the first batch, and a month or so later for a succession. All the varieties in cultivation at present seem to be derived from the two species *V. oculata* or *aspera* and *cecliorosa*; the former, however, is the race from which the variety figured has originated. Numerous other varieties, all varying more or less in habit and colour of flowers, are at present in cultivation. Among the best may be mentioned *Burridgei*, *cerulea*, *Dunnetti*, *elegans picta*, *cardinalis*, *rosea*, *hybrida*, and among the dwarf or *nana* set are *alba*, *carnea*, *picta*, *rosea*, *caerulea*, &c. They grow from a few inches to a foot or more in height, are compact in habit, and produce abundance of the most charming and brilliantly coloured flowers. They are natives of Algeria. K.

Aubrietias.—Aubrietias are an interesting class of plants, and are useful for the beautifying of the

flower beds in the spring and planting among the stones where these are used instead of Box. On the rockery also they are most useful, filling up spare places between the regular occupants. *A. Campbelli* is best suited for the latter purpose, while *violacea*, *purpurea*, and *graciosa* answer admirably for the other places named. A stock of plants can be readily obtained by sowing the seed during the early part of June in pans in a cold frame. Transplant the seedlings as soon as large enough; by these means sturdy plants are obtainable by the early part of October. The stock may be increased in the following manner, viz.: when the plants are taken up from the beds after blooming in the spring, cut off the growing parts to within an inch or so of the ground line. New growth will spring from the base of each plant, when they should be divided and planted out.—E. M.

CLEMATISES AS WALL CLIMBERS.

As Clematises are among the best plants we have for the embellishment of the fronts of houses, screens, or walls, it is surprising we do not see them more largely grown, and now is an excellent time to plant them. The plants are generally procurable in pots, and in such a manner they are easily transferred to their permanent quarters without occasioning any serious check, the main point being to make sure that any shoots which have started into growth are not broken. Where the soil is poor naturally, it is better to renew it entirely. The compost should consist of some turfy loam, peat, and some partially decomposed horse manure. When the plants are growing freely during the summer months apply copious soakings of water to the roots, and occasionally liquid manure will be of immense benefit. *Jackmanni*, deep purple, is one of the best varieties to plant, as it grows freely in any position, be it a northern or a southern aspect; this is a great consideration, as there are so few flowering climbers that will succeed in a northern position. It should be pruned in closely, say to a single eye, in February of each year; this sort is well suited for low walls. It commences to flower in July, and continues to bloom profusely during that and the next two months. *Lady Bovill* is a capital companion, as it flowers at the same time and requires exactly the same treatment as to pruning; the flowers are large greyish blue. *Venosa* is another of the same section, flowering abundantly, with purple flowers. *Sir Garnet Wolseley* is a good variety of the *patens* section, flowering in May and June, to grow where a high wall needs covering, as it requires no pruning. The flowers are pale blue, with a plum-red bar in the centre of each petal. Varieties of the *lanuginosa* type requiring moderate pruning only are numerous. *Lanuginosa* is pale lavender, having large flowers; *Gem* is a rich lavender-blue, very striking in colour; *Lady Caroline Nevill* is a fine sort, with flowers of a bluish-white colour having many bars. *Duchess of Edinburgh* requires no pruning, is a fine double white variety, blooming freely during the early part of the summer. One of the most useful kinds in a cut state, as the flowers are very fragrant and last a long time in water, is *montana*, for rambling over trellis-work or amongst other deciduous climbers. It flowers during May and June. E. M.

Lotus peliorhynchus, or Pigeon's Beak.

—It may interest those readers of THE GARDEN who have seen the mention and description of this beautiful and rare trailing plant given by my friend, Mr. E. H. Woodall, in his last interesting letter describing the flora of the Fortunate Isles, printed on p. 320 of the last issue of THE GARDEN, to know that they can see a coloured portrait of it on plate 6733, vol. ex., of the *Botanical Magazine*, drawn from a plant flowered in the cold house at the Royal Gardens, Kew, in the summer of 1881, from seeds received, in 1881, from Herr Wildprecht, director of the Botanic Gardens at Orotava, Teneriffe. It is also botanically known under the names of *Heinekenia peliorhyncha* and *Pedrosia Bertheloti*. Its local name is *Pico di Paloma*, or Pigeon's Beak. It bloomed abundantly and well during last summer

and autumn on the open-air rockwork at the Royal Botanic Gardens at Glasnevin, near Dublin, where its bright scarlet flowers were much admired. I have not, however, yet heard from Mr. Moore whether the plant has proved hardy with him or not. I should, however, fear that it would be hardly able to withstand the damp sunlessness of our winters, even if able to bear our frosts with impunity. — W. E. GUMBLETON.

FRUIT GARDEN.

W. COLEMAN.

THINNING CHOICE FRUITS.

To thorough-going practical gardeners a paper on the above subject is, of course, perfectly useless, as all good cultivators know how impossible it is to overload a tree, and yet look for superior quality. So far good, but taking the country through, I greatly question if two-thirds of the best trees in most of the leading gardens are not at times found heavily handicapped by their taskmasters. The question why and wherefore naturally arises, as all good gardeners are well aware of the fact, that the lives of their trees are shortened, the size and flavour of their fruit is depreciated, and last, but not least, their reputation as cultivators is sadly damaged. Although we occasionally walk through the millionaire's garden, in which the head is monarch of all he surveys, to find wall Peaches, of which we have heard so much of late, crying aloud for relief, it is in the smaller places where men who also understand their business, but are not allowed to have a will of their own, that this cruelty is most prevalent. Many of these gardeners would, if they were allowed, thin down to reasonable crops, which, other conditions being right, would not injure the trees in a lifetime; but in more ways than one they are debarred from exercising their own judgment. In some places the employer steps in, and quite within his right, although possibly against his own interest, insists upon this tree or that being allowed to carry so many dozens of fruit. In others, no uncommon case, the supply is unequal to the demand, and the gardener is obliged to lay on the last feather, not only to enable him to meet the pressing orders, but also to secure permission to be allowed to toil. Again, we find gardeners in good old places, from which much of the fruit is sent away as presents, cropping, as though want of colour in Grapes and size in Peaches were the very pivots on which their reputation hinges. To many these remarks may seem overdrawn; but such is not the case, as chapter and verse might be given for these and many more instances of over-cropping were they necessary. These, however, are so frequently chronicled in the pages of every horticultural paper, that all we have to do is to run over a back volume in search of notes and queries, not infrequently bearing their own answer, for strong proof of the disposition on the part of owners to overtax their gardeners' patience, as well as their fruit trees' capabilities. If this overloading brought better Grapes or Peaches to the dessert, or greater bulk to the culinary department, there would be an end of the matter; but it does neither; consequently, the only persons who suffer are the owners, whilst those deriving most benefit are the fruit-tree nurserymen. I have often pointed out the importance of timely thinning, and only last week I directed attention to the thinning of the flowers before they expand, as I know from experience that this operation is the stepping-stone to the greatest weight, the finest quality, and, as a natural consequence, the highest market value.

So far employers may appear to have the worst of the argument, but, unfortunately, it is only half exhausted and the most difficult part has yet to come, as it is generally admitted that prejudice stands firm where intelligence gives way to the mildest practical arguments. If anyone doubts this, let him turn to the question put by a lady ("H. R. C."), who, at p. 317, asks if "her gardener is right in waiting to thin the fruit till it stones, as he says it always drops off then." Further, she says, "may it not be that the fruit falls from being too crowded?" Now, this unfortunate employer is only one amongst thousands who are ready and willing to leave details to their gardeners, were they only competent and ready to wield this discretionary power in a rational way. Failing in this, it is only reasonable to suppose that employers must hold the reins until their gardeners have proved themselves competent to carry out trifling details. The lady is quite correct in her surmise that over-cropping is the most potent, although perhaps not the only, cause of dropping, as it is quite evident that something is radically wrong in the arrangement as well as the management, otherwise Peach trees would not be planted against the back walls of vineries, which are not only too hot and close, but certainly too damp and dark for them. If against his will the gardener has planted Peach trees against the back wall of a vinery the fault is not his; but he does not mend matters by deferring thinning until the fruit has passed the stoning. Indeed, were all the details thoroughly explained, it is just possible much credit may be his due for having induced the trees to set a crop that requires thinning. I once saw a house in which a gardener of some note had planted some Vines and Peaches, but the result was far from satisfactory, as it was simply impossible for him or his successor to induce the sun to shine upon two full sets of foliage at one time; consequently the two crops were reduced to mediocrity. Better, far better, give each fruit its own compartment, be it ever so small, cultivate well, and thin early. Treat the trees as trusty friends, and they will carry their fair complement of fruit to maturity.

LATE-KEEPING APPLES.

At the recent Bath bulb show prizes were offered for the best dishes of Apples, and these attracted several surprisingly good dishes of fruit. The awards were made to Ribston Pippin, the examples of this popular variety being highly coloured, plump, and of excellent flavour. Only slightly inferior to these were the handsome dishes of Cox's Orange Pippin, Blenheim Pippin, King of the Pippins, and Dutch Mignonne. Reinette du Canada and Golden Noble were also shown in good condition. From the Royal Nurseries, Exeter, came several good dishes of Apples, the best being Lord Burghley, Lane's Prince Albert (very strongly recommended as a profitable and good variety), Cornish Aromatic, Royal Pearmain, Annie Elizabeth, Blenheim Pippin, Court Pendu Plat, Cocker Pippin, Wellington and French Crab. In reality, we are not so very badly off for keeping Apples after all, and if more pains were taken in the cultivation, gathering the fruit, and storing, a supply of really good fruit might easily be maintained up to the present time, or even later. None but sound, clear-skinned, fully developed fruit will keep satisfactorily, nor should these, as was pointed out by a successful exhibitor, be gathered prematurely. If they are gathered before they are ripe, shrivelling will in all probability result; whereas if left on the tree till the seeds are brown, they will, other conditions being favourable, keep plump and good. They ought not to be moved about in the fruit-room, nor should they come into contact with straw or hay, either of these substances soon communi-

cating a musty, objectionable flavour to the fruit. Apples may be spoiled, as far as flavour is concerned, almost as quickly as Strawberries; yet, in spite of this, probably half the Apples stored in this country rests on either straw or hay. A cool, yet dry, room, clean shelves covered with paper, careful exclusion of all currents of either hot or cold air, are the conditions best calculated to ensure a long supply of good Apples. Under such treatment the season of good sorts may be made to extend over a period of five months. We had King of the Pippins fit to eat in September, and a few plump, well flavoured fruits were available during the last week in March. Very frequently those who have every facility in the shape of a well appointed fruit room do not keep Apples so well as others having no fruit room of any kind. A gentleman in this neighbourhood usually has choice varieties later than most people, and his simple plan of keeping the fruit ought to commend itself to many other amateur fruit growers as well as professional gardeners. When the Apples are ripe they are very carefully gathered, and all the soundest fruits are at once packed in clean deal boxes, which, after the lids are put on, are stored in a cool, dry room over an outhouse. They are protected from severe frosts, but never disturbed till required for use. Apples always keep better in heaps or in large boxes, only those on the surface being at all liable to premature shrivelling.

W. IGGULDEN.

HARDINESS OF STRAWBERRY PLANTS.

THE remarks in THE GARDEN (p. 333) lead one to believe that Pauline and Earliest of All are hardier Strawberries than President and others named by Mr. Gilbert. It is to be observed that Earliest of All and Pauline were grown in different quarters from the others. Might it not be a matter of local conditions, shelter, or something that makes all the difference? Even if two quarters were adjoining each other the conditions might be more favourable on one than the other; the state of moisture in the soil might tell for or against, and one might be more sheltered from the north and east. I am much interested in the degree of hardiness of Strawberry plants and fruit trees. As to the Strawberry, I have studied it and grown all the most highly recommended varieties during the last quarter of a century. If we dispense with some sorts, we are always trying others, and seldom get below twelve varieties. At present we grow thirteen, in young, well-established plants, all set out at one time as near as we could. I had noted their relative degrees of hardiness by the appearance of the old leaves, for none of them are materially injured in the heart, and the following are the hardiest, viz., Black Prince, Keen's Seedling, President, Sir J. Paxton, Waterloo, a new variety. The second hardy varieties are Pauline, James Veitch, Duc de Malakoff, Mr. Radcliffe, or British Queen, Unser Fritz, Loxford Hall Seedling, King of the Earlies, Frogmore Late Pine suffered the worst. The young leaves are now developing rapidly, and in a week or two it may be difficult to say which suffered most, and the loss of all the leaves seems to incite the plants to greater efforts to make good the loss. The whole of the varieties named have been planted together on an open space of ground. There are two to three rows of each variety containing about thirty plants in a row. March was very cold here, and even now (April 9) we have very cold east winds, with slight frosts every night. The lowest temperature in March was 17° Fahr. We have no vegetables left except some Early York Cabbage plants. Sprouting Broccoli, Scotch Kale, &c., all killed.—J. DOUGLAS.

— Supplementary to the remarks of Mr. Gilbert on page 333, may I be allowed to add the following? By far the hardiest Strawberry with us here in the north-east of England is Sir Joseph Paxton. This excellent variety has a vigorous habit of growth, with strong rooting powers, hence robust foliage, which renders the effect of a severe winter upon it scarcely perceptible. Along with Sir Joseph Paxton we may place in point of hardiness, President, Dr. Hogg, and James Veitch—all strong, vigorous growers, and remarkably large-

fruiting kinds. Another hardly class includes Elton Pine, Eleanor, and Wizard of the North. On the other hand, Sir Charles Napier is cut down considerably, as is also the British Queen; and Filbert Pine has also been damaged. The foregoing remarks chiefly refer to old plants on a strong clayey loam in a fully exposed situation. Amongst young plants Vicomtesse Hérient de Thury is our hardiest and most prolific kind. Keen's Scelling and its ally La Grosse Sacrée nearly always suffer, and their early character exposes the young and unfolding leaves to the cold north-easterly gales. All we can do is to plant them in sheltered situations, thus procuring a healthy growth in autumn; and on the approach of seasonable warm westerly winds and growing weather in the spring they grow away strongly. One of the chief causes of unfruitfulness in some kinds is the severity of the winters. Sir Charles Napier is one of the worst in this respect, and partial bareness can only be avoided by early planting and good cultivation, thus enabling the crowns to ripen before the winter commences. Of course, young plants bear the severe weather much better than old worn-out plants, and this may in some measure account for the appearance of some of the quarters where Pauline and Earliest of All are planted at Burghley. We much question, however, whether the new varieties (we have no wish to speak derogatorily of them) are very much hardier than our older and well-tried standard kinds. — J. LOVELL, *Driffield, Yorks.*

TREATMENT OF GROWING VINES.
